The source and nature of the toxins which give rise to the fatal liver changes in pregnancy have been the subject of much theorizing, but so far without definite results. The gastrointestinal tract, the liver, the kidney, the ovary, and the ovum,⁵ has each been designated as the source of the toxins, but this entire aspect of the subject is still in so much doubt that it is hardly worth while to go into a discussion of the merits of any particular theory. It is sufficient to say that, whatever its source, it is generally conceded that there is a toxin in the blood which is responsible for the morbid process in the liver.

While little or nothing is known of the source or nature of the toxins which cause the hepatic lesions, something more definite is known of the nature of the lesions themselves. Salkowski's classic experiments on autolysis of the liver were followed by Liefmann's⁶ observation of the similarity of the liver changes in fatal cases of toxemia to those of the autolyzed liver. Furthermore, some of the products arising during the self-digestion of the organ, such as leucin and tyrosin, are also present in the blood and urine in many of the fatal cases of toxemia. There is good reason to believe, therefore, that the liver changes in cases of toxemia are in reality due to a process of self-digestion. It is claimed by Wells⁷ that when the upbuilding function of a living cell is abolished by loss of its nutritive supply or impaired by the action of poisons the last function to be destroyed is the property of self-digestion. In Salkowski's experiments anabolism was necessarily abolished owing to the absence of cell nutrition, leaving the catalytic process to go on unhindered. It follows that if the higher vital process of anabolism is impaired or abolished by a poison the cell may attack and destroy itself by autolytic action. The toxins of pregnancy probably induce the liver changes in this way, through the abolition or impairment of the upbuilding function of the liver cells.

Granted that the blood during pregnancy is increasingly toxic, as claimed by Bouchard,⁸ we must then assume an insufficiency of the liver function as an essential factor in the production of the morbid symptoms and lesions of the toxemia of pregnancy. The formula for its production would be insufficient liver and toxemia on the one hand, resulting in failure of the anabolic function and autolysis on the other. The substances in the blood, noxious to the liver cells, would first merely impair the hepatic function, thereby leading to accumulation of the toxins peculiar to pregnancy, as well as those arising from ordinary metabolism, which the liver in its crippled condition is no longer able to neutralize. When the toxemia becomes so severe as to be intolerable abortion or premature labor is apt to occur through the effort of nature to relieve the condition by removal of the cause or perhaps as a direct effect of the toxins. This generally occurs before the development of actual necrosis in the liver. The wide-spread destruction of liver cells, as indicated by clinical symptoms, does not ordinarily occur until after the lapse of a period varying from a few hours to a few days after the uterus

is emptied. In other words, the removal of the primary cause of the toxemia by terminating the pregnancy, appears to have the effect of aggravating the condition, paradoxical as this may seem. This was true in four of my own cases, and is a feature of many of the reported cases of others. This peculiar behavior of toxemia cases is especially noticeable in those which begin as catarrhal jaundice during local epidemics of this disease. These cases do not appear to be at all serious until after delivery, when the symptoms of acute yellow atrophy supervene and lead rapidly to a fatal issue.

This tendency of toxemia cases to become worse after removal of the primary cause is a matter of supreme clinical importance, and it is surprising that it has not attracted more notice from obstetricians. So far as I can learn from the current literature on the subject, there seems to have been no attempt to ascertain its cause or to forestall its effect. Recognition of this peculiarity of these cases forces the conclusion that a new supply of toxins must enter the circulation after the uterus has been emptied. It seems to me that the source of these new toxins is not far to seek. The postpartum uterus loses weight rapidly after being emptied of its contents, the loss during the first week approximating 50 per cent, according to Williams's⁹ figures, the freshly delivered uterus weighing about 1,000 grams and only 500 grams one week later. This rapid atrophic process undoubtedly results in large quantities of waste products being thrown into the circulation. The burden of neutralizing these products, which must be toxic inasmuch as they are excrementitious, falls on the liver, which in its crippled condition is unequal to the task. The impending necrosis of liver cells then becomes actually established.

Of interest in this connection is the fact that there is reason to believe that the process of involution of the uterus is itself essentially a physiologic autolysis of the organ, rather than a simple atrophy or fatty degeneration, as heretofore taught. This idea is borne out by the occurrence of peptonuria during the puerperium. Levene¹⁰ refers to it in his article on autolysis, and something like the same idea must have been in the mind of Fischel,¹¹ before the advent of the doctrine of autolysis, when he advanced the theory that involution is due to the conversion of the hypertrophied uterine muscle into peptone, and its excretion in the urine. Peptonuria presupposes peptonemia, and, as is well known, peptones and albumoses are toxic when present in the blood. It is not to be inferred, however, that these are the only toxic substances resulting from the retrograde process in the uterus. I presume it will be understood that by the terms peptonuria and peptonemia the presence of albumose in the urine and blood is meant instead of true peptone, which is never present in either fluid unless artificially introduced.

Granted that the toxins resulting from the retrograde change in the postpartum uterus are apt to be the determining influence in the actual development of an impending necrosis in the liver, the importance of forestalling their effect is obvious. This can only be done by terminating the pregnancy at an earlier date than would otherwise seem necessary. In other words, it is not enough merely to determine whether the liver can withstand the pregnancy toxemia, but allowance must also be made for the additional postpartum dose. An-

other element which is no doubt sometimes the determining factor in an unfavorable case is the anesthetic. While this applies especially to chloroform, it must not be forgotten that in order to produce complete anesthesia a toxic dose of an anesthetic is necessary, and, as heretofore stated, all the inhalation anesthetics are to some extent liver poisons.

PATHOLOGY

The liver is the principal seat of the pathologic changes induced by the toxemia of pregnancy. The process consists essentially of a degeneration and necrosis of the cells of the liver lobules. Any of the three zones of the lobule described by Virchow may be affected by the necrotic process, but a careful analysis of published reports would indicate that it attacks by preference the central and mid-zonal areas. Schmorl¹² believes that necrosis beginning in the peripheral zone is typical of eclampsia, and his views are confirmed by Williams.¹³ Both observers, however, attribute the necrotic process in eclampsia to secondary changes dependent on thrombosis of the vessels in the interlobular spaces. This explanation of the hepatic necrosis in eclampsia serves to support the view advanced by Williams that eclampsia is due to a different kind of toxemia from that giving rise to pernicious vomiting and acute yellow atrophy. According to this explanation the variety of toxemia which gives rise to eclampsia produces thrombosis primarily, the necrotic changes being a secondary effect, while the toxemia which results in pernicious vomiting and acute yellow atrophy is the direct cause of necrosis of the liver cells. Ewing¹⁴ considers that eclampsia, acute yellow atrophy and pernicious vomiting are simply different manifestations of the same toxemia. While this question remains to be definitely settled, it is my belief that the diversity of the two types of toxemia will ultimately be established. In addition to the well-recognized differences in symptoms and pathology, between acute yellow atrophy and pernicious vomiting on the one hand and eclampsia on the other, there is a striking difference in their behavior after the uterus is emptied. Barring exceptional cases, the tendency of eclampsia is to get better a few hours after delivery, while that of the other variety is unmistakably in the opposite direction. Furthermore, they differ in prognosis, uncomplicated eclampsia being a much less fatal disease than acute yellow atrophy or pernicious vomiting. It is not unlikely that mixed types of toxemia may occur, giving a clinical picture that may be interpreted as eclampsia or acute yellow atrophy, according to the bias of the individual observer. The existence of these mixed types may be the cause of much of the unfortunate confusion in the terminology of this subject.

In addition to the lesions in the liver, degenerative changes are present in the kidneys and heart, and in eclampsia, small thromboses in the brain and lungs.

SYMPTOMS

Vomiting is a prominent symptom of toxemia. When occurring in the early months this symptom dominates the picture to such an extent that the condition is classed as a clinical type under the name of pernicious vomiting of pregnancy. This early vomiting is apt to be confused with the benign type due to reflex or neurotic influences,

but in the later months its significance is not so apt to be overlooked.

Headache is a common symptom, as are also neuralgic pains in other parts of the body. Epigastric pain, probably due to the liver changes, is especially significant. Increased secretion of saliva is an important symptom present in many of the bad cases. It is most noticeable at night during sleep. The patient on waking finds a spot on the pillow, due to the dribbling of saliva from the mouth.

Air hunger, described by Kussmaul¹⁵ is a fairly constant symptom. It was a prominent feature in three of my four fatal cases and in four out of five cases seen with others.

Extreme mental depression is present in many cases. The patient takes a most gloomy view of her condition and frequently expresses a conviction that she will not recover.

Edema of the extremities or face is frequently noted, although it is by no means a constant feature. Albumin may or may not be present in the urine. Evidences of disturbed metabolism, however, may be rather constantly found.

All these symptoms precede the development of the necrotic process in the liver and are due to the toxemia itself. Those which depend on the destruction of liver cells are coma and stupor, black vomit, bile in the urine, possibly icterus, rapid breathing, convulsions (always in eclampsia, occasionally in acute yellow atrophy), failure of renal function, failure of circulation. Death is the rule after the advent of these grave symptoms, though regeneration of the damaged liver cells and recovery is possible.

DIAGNOSIS

Valuable work has been done by Williams, Ewing and others toward establishing laboratory aids to the diagnosis of toxemia of pregnancy. Ewing first called attention to the diagnostic significance of unoxidized proteid derivatives in urine, while Williams was the first to point out the special significance of an increased percentage of ammonia. The normal amount of ammonia in the urine is from 3 to 5 per cent, and Williams considers it a danger signal when the percentage reaches 10 or more. I am in no position to express an opinion as to the practical clinical value of this test, having had no experience with it. There can be no doubt, however, that the test is based on logical grounds. It is well known by physiologists that when in an animal a part of the portal blood is diverted from the liver and carried directly into the general circulation by means of an Eck fistula between the portal vein and vena cava a considerable part of the urea nitrogen appears in the urine as ammonia.¹⁶ Almost all the urea is represented by ammonia if the liver is entirely shunted out of the circulation by ligation of the hepatic artery and of the portal vein on the liver side of the fistula. In the light of this experimental data it is to be expected that hepatic insufficiency in the human subject would result in a similar disturbance of the ratio between the urea and ammonia output. While there can be no doubt that the presence of an increased percentage of ammonia in the urine is an indication of a dangerous hepatic insufficiency, it is denied by Ewing¹⁷ that its absence is necessarily of favorable significance. It is to be regretted that the estimation of unoxidized proteid derivatives,

and especially the ammonia coefficient, is so complex a chemical procedure as to be available only to those who have access to the services of a skilled chemist. The diagnosis must, therefore, continue for the present to rest almost entirely on the clinical symptoms

TREATMENT

Palliative measures, to be effective, must be directed not only against the toxemia but quite as much against the hepatic insufficiency. No method of treatment hitherto employed has appeared to influence favorably the impaired antitoxic function of the liver. Eliminative and dietetic treatment, intended to reduce the toxemia, while sometimes successful, too often merely postpone the crisis, the morbid condition reappearing at a later date in aggravated form. I have seen several cases behave in this way, and many other examples may be found in the literature. In view, therefore, of the impracticability of treating the hepatic insufficiency, and the unreliability of treatment of the toxic condition itself, it seems to me that palliative measures should have no place in the management of a recognized case of toxemia of pregnancy.

Radicalism is, then, the only alternative, and in the interest of the patient it should be resorted to early and without reference to the interest of the fetus. Assuming that the diagnosis is established, the indication to empty the uterus is just as urgent as the indication to operate in a case of recognized ectopic pregnancy before rupture. If the condition arises during the early months the question as to whether to empty the uterus at one sitting or to induce abortion by a slower method must be decided according to the urgency of the case. On account of the possible unfavorable influence of anesthesia, non-operative induction of abortion should be given preference, other things being equal. This rule should also be followed in the later months for the same reason. A protracted labor should not be permitted, however, as the excessive muscular exertion would add its quota to the toxemia already existing. If the case is very urgent, rapid delivery may be accomplished by means of whatever obstetric operation seems to be best suited to the case. Cesarean section may be performed by either the vaginal or abdominal method, provided that the exigencies of the case appear to call for such an operation. If, however, for any reason it is seen fit to perform the abdominal operation, the question arises as to whether it would not be advisable to remove the uterus at the same time in order to avoid a probable increase in the toxemia as a result of the process of involution.

In any operative procedure on a patient with toxemia inhalation anesthesia should not be employed if it is possible to avoid it, for reasons already stated. Spinal anesthesia, free as it is from the disadvantages of general anesthesia in this condition, is worthy of favorable consideration. In any event, chloroform should never be used in a case of toxemia of pregnancy.

REPORT OF CASES

CASE 1—Mrs J P A., aged 19, primipara, was seen with Dr Wyatt Heslin.

History—Pregnancy was uneventful until the beginning of the eighth month, when she contracted what appeared to be an attack of catarrhal jaundice, a disease which was prevalent in the neighborhood at the time. The jaundice continued for two weeks, when labor came on, Jan. 14, 1903, about two weeks before full term. Spontaneous delivery occurred in four hours. The patient's condition was apparently normal except for jaundice, until forty eight hours after delivery, when she gradually

sank into a stupor and died January 17, about seventy two hours after delivery. A few hours before death she vomited a quantity of coffee-ground material. A specimen of urine obtained just before death contain leucin crystals, and this finding, together with the clinical picture, led to a diagnosis of acute yellow atrophy of the liver. The case was reported as such before the Jefferson County Medical Society, Feb 9, 1903. Postmortem was not allowed.

CASE 2—Mrs A. E S., primipara

History—Pregnancy presented no abnormal feature except edema of extremities and face. The urine was examined repeatedly for albumin and casts, but always with negative results. Labor, about full term, began Sept 9, 1904. After twenty four hours' useless labor delivery was accomplished by version. Chloroform anesthesia was used and was somewhat prolonged on account of repairing an extensive perineal laceration. The patient's condition was good until the morning of September 13, sixty hours after delivery, when she was found by the nurse in a partial stupor. This steadily deepened, and jaundice appeared a few hours later and rapidly increased. Death occurred September 14, eighty four hours after delivery. Post mortem was not allowed. Neither leucin nor tyrosin crystals could be found in the urine. A diagnosis of acute yellow atrophy of the liver based upon clinical symptoms alone.

CASE 3—Mrs C H C., primipara, aged 34

History—Nausea and vomiting, with albuminuria, appeared about the end of the third month. The condition improved remarkably on a milk diet and eliminatives. Under this treatment the woman's condition remained apparently normal until the end of the seventh month, when the symptoms returned rather suddenly. After a few days of palliative treatment labor was induced, and after a tedious labor delivery was accomplished by forceps under chloroform anesthesia. Black vomit appeared while she was still under the anesthetic, and consciousness never fully recovered. Urine was very scanty after delivery, and contained albumin, casts, and bile pigment. Death occurred thirty six hours after delivery. No postmortem.

CASE 4—Mrs I L A., second labor

History of Previous Pregnancy—She was attended by me in her first labor, May 16, 1901. She had suffered very much from nausea and vomiting during that pregnancy. Delivery was accomplished by forceps. Twenty four hours after delivery a mild, acute mania developed, which lasted about one week. Convalescence was slow, but finally resulted in complete recovery. She was advised by me not to attempt to go through another pregnancy, but after two years of fairly good health, she again became pregnant in August or September, 1903.

Subsequent Pregnancy—In this pregnancy she almost lost her life from pernicious vomiting. She steadfastly refused to consent to the induction of abortion until she was in a desperate condition. Abortion was finally induced, however, and she made a slow but satisfactory recovery. She became pregnant again five months later, and got through the early months very well compared to the previous pregnancies. At the beginning of the sixth month, however, persistent vomiting set in, accompanied by scanty urine and albuminuria. She again refused to consent to having the pregnancy terminated until she began to suffer from "air hunger." She then consented to have labor induced, but her symptoms rapidly grew worse, and she had already sunk into partial coma before the preparations for delivery had been completed. The delivery was accomplished by version, the necessary dilatation of the cervix being obtained by means of the Bossi dilator. The entire proceedings were completed in thirty five minutes, and without damage to the maternal structures. A very small quantity of chloroform was given, very little being required, owing to the partial stupor. Her pulse was almost imperceptible at the time of operation, and failed to respond to stimulation during and after the delivery. Death occurred four hours after delivery. Postmortem was not allowed.

CASE 5—Mrs W G O., third pregnancy

History—The patient suffered from headache, pressure, edema of face and extremities, insomnia, albuminuria, scanty urine and profuse salivation.

ment occurred under palliative treatment. Labor was induced at the seventh month of pregnancy, and a living child was delivered. Recovery was uneventful.

CASE 6—Mrs J D H., was seen with Dr R B Harkness, third pregnancy.

History—Eclamptic convulsion had occurred after the first labor. The second pregnancy and labor were uneventful. One convulsion occurred at the fourth month of the third pregnancy. Improvement took place under palliative treatment. The woman had an easy labor at full term. Rapid pulse and labored breathing with partial stupor developed a few hours after labor. The condition was exceedingly grave. Convalescence was slow and complicated by endocarditis and thrombosis of the veins of the left arm.

CASE 7—Mrs W H. T. was seen with Dr D F Talley.

History—The principal symptoms were "air hunger" and vomiting of coffee ground material. Pulse was rapid and weak. Premature labor was induced by Dr Talley and recovery was uneventful.

CASE 8—Mrs J O T. was seen with Dr D F Talley.

History—This patient suffered from persistent vomiting of coffee-ground material, which gave the blood reaction with the guaiac test. There were also present mental torpor and profuse salivation. Premature labor was induced by Dr Talley and recovery was uneventful.

CASE 9—Mrs B. was seen with Dr E S Casey.

History—Spontaneous abortion occurred Sept 27, 1906, in the third month of pregnancy. The uterus was curetted on account of retained secundines, Oct 4, 1906, under ether anesthesia. Temperature remained high, and on the day following the curettage, coma and jaundice appeared. The jaundice deepened rapidly, coma became profound and death occurred Oct 6, 1906, eight days after the abortion. Postmortem was not permitted.

INFLUENCE OF THE MOTHER'S HEALTH IN PREGNANCY ON HER UNBORN CHILD *

J W BALLANTYNE, M D, F R C P E

President Edinburgh Obstetrical Society. Lecturer on Obstetrics and Gynecology, Surgeons' Hall and Medical College for Women, EDINBURGH.

There are three epochs of a child's life during which the mother's influence is supreme. The middle period of the three is that of lactation, and it is followed by a time of varying extent, lasting usually till the child goes to school, while it is preceded by an antenatal epoch of at least nine months' duration. It is with the last named of the series only that I am here concerned, but it may make for lucidity if I indicate briefly the kind of influence which a mother exerts during the other two periods, both of which are distinguished from the third by the fact that they are postnatal. I will call the three epochs in their order 1, Antenatal, 2, lactational and, 3, postlactational.

The *postlactational period* of influence extends from the time of weaning, which may, perhaps, be stated roughly as occurring at the ninth month of the child's life, to the year when the child goes to school or in some other way passes from under the immediate supervision and control of the mother. During these years, which may be estimated at five or six, the mother's influence over her child is preëminent, it is not, however, exclusive of all others, for the father, the nurse, or brothers and sisters, may all have a certain degree of control over the health destiny of the young child growing up among them. Nevertheless, the maternal influence far outweighs that of all the rest combined, and it may be stated generally that the mother deter-

mines what shall be the food of her child, what shall be his clothing, what the amount and kind of exercise shall be, what shall be the physical surroundings, and vastly more subtle, what the moral and religious atmosphere. If she be a wise mother she will endeavor to supply him with food suited to his age and requirements, she will see to it that he is clothed in accordance with the needs of exercise, indoors or outdoors, and with the varying conditions of climate and season, and she will take care that his body hygiene, as well as that of his nursery and playroom, be the best that can be obtained. In all these matters she will ask for, and ought to receive, the best advice from her medical attendant, and, if she employ a trained nurse to look after her child's interests during a part of the day or night, she ought to choose one capable of understanding the reasons for the rules of health in childhood. She will endeavor also to shield her child from epidemic and exanthematous dangers, and from the more persistent and pernicious effects of bad habits acquired in early life. It is no exaggeration to say that, for the proper performance of a mother's functions, as they are mapped out above, a very large part of a mother's time must be set aside. That all women who have borne children are not willing to devote so much time to the business of influencing their offspring's future is a commonplace, but such women can hardly lay claim to the name of mother, for a mother's duties do not cease with the close of the third stage of labor.

In the *lactational period*, the first nine months of postnatal life, the infant's welfare is even more dependent on the mother's care and interest. Her influence is now more than preëminent, it is practically exclusive. The child is drawing his entire nourishment from the maternal tissues, he is watched over by his mother day and night, nothing, it may be said, can happen to him without her knowledge and consent. Her dietetic errors are reflected in his arrested nutrition, her emotional disturbances and social distractions are transmuted into his digestive disorders, and the diseases from which she may suffer may either be passed on to him or in less direct ways, by altering the composition of her milk, may affect the performance of his bodily functions. Should she become pregnant while nursing, both the infant at the breast and the fetus in the uterus will feel the strain that is thus put on her organism. I need not linger over this period of maternal influence, for I think every one admits that the state of an infant is a very fair test of the structural and functional integrity of his nursing mother. Neither, unfortunately, is there any need to inform the medical practitioner that mothers, some of them perhaps from inability, others more likely from disinclination, too often are not found standing in this close relationship to their young infants. There may be dangers to the infant from drawing his supply of milk from her breast, but the dangers are multiplied when he has to depend on the cow or the manufacturer of artificial food, although I freely admit that the cow has often proved a benefactor and that the manufacturer has sometimes shown ability and ingenuity.

THE ANTENATAL PERIOD

But it is more with the influence of the mother on her child in the antenatal period of his existence that I have to do here. The extent and character of this influence are to a large degree unknown to or unconsidered by many medical men. Too often physicians allow notions of the

* This paper was prepared to be read in the Section on Diseases of Children at the Fifty-seventh Annual Session held at Boston June 1906.

potency or impotency of maternal mental and emotional impressions to prejudice their whole conception of the prenatal relationship existing between mother and fetus. While I do not affirm that a mother's mental and emotional state during pregnancy has no influence on her unborn child (indeed, I believe there is such an influence), yet I deplore the fact that scientific men have been led away from the plain facts and ascertainable phenomena of the transplacental transmission of maladies, predispositions and immunities to the consideration of such a will-o'-the-wisp as the effect of the mother's imagination.

While, no doubt, mental depression and emotional disturbances take their place among other etiologic factors and have an effect on the mother's general health, and so on that of the fetus, just as on that of the suckling, yet the influence of such states is probably slight compared to that of, say, toxins in the mother's blood and diseases of the placenta. But that a maternal mental picture, pleasant or unpleasant, can impress itself on the body of the fetus as a photographic negative is reproduced on a print is, in my opinion, entirely without scientific basis. Such a belief has been the cause, direct and indirect, of a great deal of misdirection of inquiry, and the nature of the results obtained has been such as to bring to the whole subject a certain measure of disrepute.

The subject I shall endeavor to discuss is, then, how the state of the mother's health in pregnancy influences that of the child to whom she is to give birth, and, with what I have said above, I shall dismiss the ancient but discredited theory of maternal impressions and pass to views which can commend themselves to the scientific mind.

THE RELATIONSHIP OF FETUS TO MOTHER

First, it is necessary that a clear conception exist as to the relationship of the offspring to the mother before birth. I do not intend to consider the manner in which the ovum in the Graafian follicle is influenced by the maternal metabolism, nor do I intend to deal with heredity at all, I shall limit the discussion entirely to the influence of the maternal on the embryonic and fetal organism, during the nine months of pregnancy, which is a completely different matter from heredity, as heredity is generally understood. It is true that heredity and the influence of the mother on her offspring in pregnancy are constantly being confused and even regarded as one and the same thing, but they are distinctly different, unless, indeed, we are prepared to call the influence a woman has on her child at the breast, through her milk, a hereditary one, and this assumption, I think, few will allow. I exclude heredity, therefore, not because I do not admit its action, although I believe we know extraordinarily little about it, but because I wish to focus attention on the much less hypothetical effect produced by the state of the mother's health on that of her infant *in utero*.

THE PHYSIOLOGIC RELATIONSHIP

In the early weeks of pregnancy the impregnated ovum, embedded in a mass of cells which may be conveniently termed the trophoblast, is attached to the wall of the uterine interior, processes from the trophoblast push their way into the uterine blood sinuses in the mucous membrane at the site of attachment, and embryonic blood vessels invade the processes and so come to be bathed in the maternal blood with only a layer or two of trophoblast cells intervening. As the

weeks pass by, specialization takes place and there is formed a definite placenta in which villi, with continued fetal vessels, lie in pools of maternal blood, but the essential character of the relationship remains the same. The fetal and maternal bloods do not mix, unless, indeed, a hemorrhage into the placenta takes place, but they are sufficiently near each other, and the intervening tissues are sufficiently porous, to permit the passage of fluids, gases, and even of solids from the one blood to the other. This is what I mean when I speak of the transplacental interchanges. The laws of these exchanges are not yet fully known, but enough has been ascertained to lead us to believe that there is a constant flow from the maternal into the fetal blood of oxygen, water, chemical substances (such as lime, iron, potash, and soda) in solution, proteids, fats, and even of white blood corpuscles. From the fetal into the maternal blood there is a reverse current consisting mainly of effete materials to be ultimately got rid of by the mother's excretory organs. It also is known that under exceptional circumstances other things pass over from the one organism to the other, among which may be mentioned poisons, toxins, microbes, and agglutinins. Why in one case these exceptional substances pass over and in another case do not we are not in a position to state. The easiest explanation of their passage, as the occurrence of a hemorrhage or of disease in the placenta breaking down the tissues intervening between the two bloods apparently does not apply to all cases, although it may be accepted for some. We must, no doubt, look on the peculiar states of the fluids on the two sides of the placental barriers as the cause, and the discovery by physiologists of the regulating factors in the transmission of fluids through animal membranes in other parts of the body, will very likely aid us before long in the solution of this antenatal problem, unless, indeed, the solution of the antenatal problem antedates that of the postnatal one.

It is an interesting question whether or not there is any other route by which materials may pass from the mother to the fetus or in the reverse current from the fetus to the mother. I think there is some evidence to show that in some instances, at least, there may be a circulation of the liquid amnion and that in this way substances may so pass, thus escaping the placental barriers. In other words it seems likely that some chemical substances in solution may transude into the amniotic fluid from the maternal tissues of the uterine wall and be swallowed by the fetus and so reach the fetal tissues.

COMMUNICATION BETWEEN MOTHER AND FETUS

I am now in a position to refer to the influences which by one or the other or by both of these routes may pass from the maternal to the fetal organism. The most familiar instances are those in which the mother has an infectious disease, such as smallpox or measles and gives birth to an infant with obvious signs of the disease in question on it. There are two possibilities in such an occurrence. Either the cause of the maternal disease has passed through the placental or amniotic barriers and affected the fetus also, or else the infecting substance whatever be its nature, has affected both the maternal and fetal organisms at the same time. In other words it is not certain whether the mother is first infected and then infects the fetus, or whether the latter is simultaneously infected with her. It may be said that the incubation period in the case of the fetus will show which is the correct view, but there is a difficulty for the data

are difficult of ascertainment and there is always a probability that the incubation period may be shortened in the case of two organisms so intimately in contact with each other as those of mother and fetus

Other instances are those in which a disease, caused by a special microbe, is transmitted from mother to fetus, as is proved by the discovery of the microbe in the placenta and in the tissues of the fetus if it should be born dead. Such maladies are fetal sepsis and fetal tuberculosis. It is true that the latter is extremely rare, but it is also true that a few absolutely proven cases have been recorded. Further, when the tubercle bacillus surmounts the placental barriers, there is abundant evidence that it finds in the fetal tissues a suitable culture medium, for in the authenticated instances of fetal tuberculosis the disease has been of that virulent type which is usually seen only in birds (avian tuberculosis). We are forced, then, to conclude that the placenta plays a strongly protective rôle in connection with the unborn infant of a tuberculous mother. Perhaps other microbes attack the placenta itself, rather than other tissues, and so more readily overcome its opposition while the tubercle bacillus is held in check by some chemical substance in the placenta or by an essential weakness in itself. The vitality of the placenta is probably very high, on account of the large amount of epithelial tissue it contains, and so perhaps its resistance to bacilli is great. If this be so, it will account for the ready passage of microbes which thrive in strong tissues and for the difficulty of passage of such as breed best on devitalized structures.

Again, there is another group of diseases which are not transmitted to the fetus in the same form as that which they exhibit in the mother. Typhoid fever, for instance, is known to have an effect on the fetus, for the germs of it have been found in the fetal tissues in cases in which the mother has suffered the disease and given birth to a dead infant. But, probably on account of the inactive state of the fetal intestine, or by reason of the umbilical mode of entrance of the germs into the fetal body, the malady takes the form of a general blood poisoning rather than that which is associated with typhoid in the adult. Here, then, it may be that the mother's disease causes morbid changes in the unborn infant which are not those occurring in the maternal organs, but which are due to the same microbe. Possibly, also, diseases not yet shown to be due to a microbe, such as eclampsia, influence the fetus in this obscure manner, perhaps toxins pass the placental barriers and disturb the nutrition of the fetus. It may be difficult to find a name for these diseased states, they are semi-diseases, but I think that their existence is undoubted and I have given a chapter to their consideration in my recent work "Manual of Antenatal Pathology".¹ The occurrence of morbid states in the fetus due to the passage of toxins from the mother, due in their turn to diseases of the mother leads me to refer to fetal maladies caused by the invasion of the body of the unborn infant with toxic materials—such as lead, alcohol and mercury. There is every reason to believe that the placenta acts as a barrier to the passage of these substances also, but it occasionally fails either by reason of the great amount of the poison or on account of the presence of disease in the placenta. The placenta also seems to save the fetus by storing up the poison in itself, as does the liver in the adult, and this fact, I think, explains how it is that the usual result,

when the placental safeguard is broken down, is the expulsion of a dead fetus and not a diseased one. The poison has spent its force on the placenta, and by destroying it has killed the fetus, there has been no time for the poison to produce its specific effects on the fetus.

It must never be forgotten in dealing with fetal pathology that the placenta is one of the fetal organs, and a very vital one, and that when it is attacked and injured the results to the unborn infant are very serious, much more immediately serious than if, for instance, the fetal lungs, stomach, brain or kidneys were grossly degenerated. This is probably one of the chief reasons why maternal syphilis has so terribly disastrous an effect on antenatal life, for it causes such marked lesions in the placenta.

I have here attempted the merest sketch of the influence which maternal maladies, alcoholism, drug habits and the like may have on the unborn infant, and I have not touched at all on the effects which these same morbid agents may have on the organism in the embryonic stage of its antenatal existence. I believe the latter changes to be teratologic, not pathologic, but into that very large question I do not propose to enter.

SUMMARY

1 All diseased conditions of the mother in pregnancy, whether due to microbes, toxins, toxic agencies or diatheses, are, I believe, dangers to the fetus.

2 The fact that the fetus sometimes, perhaps often, escapes must be largely ascribed to the protective influence of the placenta.

3 The morbid influence may either force its way through the placental barrier and so reach the fetus and cause disease, etc., in it or, by destroying the integrity of the placenta itself, it may cause death of the fetus.

4 The laws that regulate the placental interchanges, normal as well as pathologic, have not yet been discovered.

5 The great safeguard of the fetus, if the mother be diseased, is a healthy placenta which opposes the passage of germs and toxins and which is not itself liable to the attacks of these morbid agencies.

6 We do not yet know if there are any medicines which act, as it were, as placental tonics, perhaps potassium chlorate and mercury are of this nature and possibly some of the organic extracts may be found to have this action.

SURGICAL ANESTHESIA,

WITH SPECIAL REFERENCE TO POSTANESTHETIC NAUSEA AND VOMITING

W. TURNOR WOOTTON, M.D.

Attending Physician Ozark Sanatorium, Secretary U. S. Medical Commission

HOT SPRINGS, ARK.

Much has been said and written on the important subject of anesthesia. Still there has been one particular point that has as yet never been satisfactorily settled, so far as I am able to learn. I refer to the distressing nausea and vomiting that so often follows the administration of ether and chloroform.

After having exhausted such methods as lavage, filling the stomach with water prior to the operation, pungent odors to nostrils, hypodermic medication, etc., without any apparent beneficial result, I began experimenting with a measure at once simple in use, logical, harmless and, to my mind, expedient.

¹ Illustrative instances of the statements made in this article will be found in abundance in this work especially in Chapters XI to XVI.

servations, histologic studies, all lead to this view that a cooperation of all constituent portions of the brain is necessary for a normal function of intellect and that only a diffuse alteration of the brain is able to produce a modification in intelligence. Nevertheless, the anterior portion, the so-called prefrontal lobe, has been recognized since Gall, as the preponderantly better developed in highly intellectual individuals and that mental deficiency goes hand in hand with abnormal frontal lobes. According to Meynert, the weight of parietal and occipital lobes together, is to the frontal lobe as 3 to 6.

Pathologic studies of the brain have thrown considerable light on the question of localization of higher psychic function. Sifting all the accumulated data, especially those concerning cerebral tumors, the conclusion can be drawn that while a lesion of any portion of the brain is capable of giving place to mental disturbances, yet on the other hand most pronounced lesions are sometimes unaccompanied by disturbed psychic functions, nevertheless it is generally admitted by the majority of observers, that a tumor or any lesion of the prefrontal region, particularly of the left (Phelps) is more frequently attended by mental disturbances than a lesion of any other portion, except, perhaps, of the corpus callosum. Attempts have been made to determine whether or not, among all possible normal mental

Apparently recent hemorrhagic area in the white substance of the left prefrontal lobe.

phenomena, there are some that are especially characteristic of the function of the prefrontal area, also whether in pathologic conditions of the same region special abnormal mental phenomena are present.

Among all possible lesions of the prefrontal lobe, tumors are the best studied and indeed the majority of observations concern those of prefrontal neoplasms. Léonora Welt¹ made a careful study of eight cases of various lesions of the prefrontal lobe and noticed the following mental symptoms. The patient is morose, taciturn suspicious, and at times violent. L. Steven² concludes from his studies that patients thus affected are very facile in temperament, unable to concentrate their attention and present loss of memory for recent events. Bianchi, who made exhaustive studies of the subject, points out the following mental symptoms: Restlessness, indifference, great irritability, want of criticism, automatism. Flechsig, who places in the frontal lobe one of his association centers, finds in diseases of this area a loss of sense of relation of personal consciousness to outside influences, inability to discriminate possibilities from impossibilities and, finally, loss of self-control.

Summing up the opinions of all observers, the following are the principal symptoms: Mental hebetude, automatism, excitement and irritability, or else depression, disorientation and loss of power to concentrate attention. The German writers long ago called attention to a special symptom, which they found in a large number of cases in diseases of the prefrontal lobe. Jastrowitch gave it the name *Moria*, Oppenheim calls it *Witzelsucht*. The characteristic feature of this symptom is the humoristic spirit which is seen in the patient's actions and words. Although it is not present in every case, and this symptom was observed in tumors of other areas of the brain, it is nevertheless admitted by many writers³ to be present more frequently in affections of the prefrontal lobe than of any other region of the cerebrum.

The patient, whose history, I am about to relate, presented during life in addition to excitability, disorientation, motor restlessness, indifference to surroundings, inability to concentrate attention, all symptoms to some extent characteristic of prefrontal lesions (see above)—a state which can be called "euphoria." This term is a more general expression of the happy, contented state of mind. It is certainly allied to *Moria* and *Witzelsucht*, but it is broader in its conception. The case is highly interesting because of the appearance of mental phenomena shortly before death and at autopsy a recent hemorrhage was found in the left prefrontal lobe.

History—J. M. R., aged 34, upholsterer, had a hemiplegic attack at the age of 25. He improved rapidly, so that at the end of six weeks he returned to work and remained at his place of business until about five days before death. The hemiplegia persisted to a mild degree, but his speech was somewhat impaired. The mental faculties were intact, as he was able to carry on his business, his transactions with his customers and his relations to his family being perfectly normal. About five days before death, while seated at the table, he suddenly became unconscious. A few minutes later, when his consciousness returned, he showed marked confusion. On the following day he became restless and violent. He would strike any one who approached him.

Examination—When I saw him he presented no new localized symptoms in addition to the old mild hemiplegia on the left. The mental phenomena were very interesting. He was indifferent to surroundings. It was almost impossible to hold his attention for longer than one minute. Questioned about events or objects familiar to him he would give one or two answers, but would immediately take up another subject. He was very restless, threw off the bedclothes, then sat up, lay down and so on. He ignored the presence of females, as he frequently uncovered himself. Asked where he was, he replied, "in Paradise." The most striking symptom was the constant passing of his hands over his face and putting his hair and moustache in order. He insisted on having a mirror on his table, would incessantly look in the mirror, and express pleasure at seeing himself in good shape. He often repeated the word "pretty" or "handsome." When any one would enter the room he would sit up suddenly, grasp the stranger's hand, pull him and twist his fingers, repeating continuously the words "glad to be with you." Every act and word expressed enchantment. Whoever appeared at the door, he claimed to know well and asked to remain. At times he would attempt to joke with the stranger, saying he sent him flowers or a check the day before, and then would laugh aloud. Then again he would forget it and return to his mirror and to putting himself in good shape, totally ignoring every one around him. This was evidently done in an automatic manner. Any article of food tasted delicious, he expressed pleasure at anything offered him. He was unable to sleep. The condition lasted four days when

3 Schuster, Psych. Störung bei Hirntumor and Glaucom II. Pölslein, 1907.

the patient gradually became comatose and expired at the end of the sixth day

Autopsy—At autopsy I found, besides an old softening in the right internal capsule, a recent hemorrhagic area in the white substance of the left prefrontal lobe (see illustration). Microscopic examination of the brain and the spinal cord shows the descending degeneration traced from the right internal capsule. It may be of some interest to know that the patient had a tendency to bleed easily and profusely on the slightest occasion. This factor probably was the immediate cause of the cerebral hemorrhage.

The present case is interesting therefore, because of the causal relations of a lesion in the left prefrontal region to the mental phenomena and because of the special character of the latter, similar to those observed by other authors. The euphoria of the patient was striking, he expressed a psychic childishness in his acts and words. Since an analogous symptom was observed by others, viz, *Witzelsucht*, *Moria*, and since in my case it was the most conspicuous phenomenon throughout the man's brief illness, perhaps it could be considered to some extent as pathognomonic of diseases of the frontal lobe. This contribution to the study of pathology of the prefrontal lobe adds a new, although not absolute, proof of the localization of the higher psychic functions in this region of the brain.

ACUTE OVERSTRAINING OF THE HEART *

THEODOR SCHOTT, M.D.

FRANKFURT-ON MAIN, GERMANY

It is now about thirty years since Peacock, as a result of observations made by him on Cornwall miners, acquainted us with a special form of heart disease, the etiology of which he tried to connect with previous muscular straining.

His observations were confirmed later on by the investigations of Myers, Clifford Albutt, Da Costa, Joh Seitz, Munzinger, etc. Nevertheless, there were other authors that did not admit of a condition of excessive heart-straining, or at least were very doubtful about it, as, for instance, v Schroetter, E Seitz and Strumpell. It was the investigation of Leyden and Fraentzel which again gave new impulse in this domain, and in one of my publications I was enabled to mention these observations of cases which correspond with those of both last-named authors.

We naturally have to distinguish between a chronic and an acute overstraining of the heart, and it is hardly necessary to mention that the first can result only from an accumulation of repeated single overstrainings, the investigation of the latter is, therefore, of extraordinary interest. Many former doubts have been dispelled by a series of observations (Leyden, Fraentzel and myself), as well as by a better knowledge of the physiology of the heart. Nowadays we possess a better knowledge of the innervation of the heart and are also better acquainted with the functions of the pneumogastric and sympathetic and of the extra- and intracardiac nervous centers—I refer, among others, to the coordination center of Kronecker-Schmev, etc. All this may help to clear many misunderstandings which may be of consequence in the different manifestations of heart-overstraining. The numerous investigations on the intracardiac as well as on the intravascular pressure command attention

also the exact determination of the time-limits of the rhythmic cardiac movements, and above all the reflex actions which may influence the activity of the heart from the lungs, the blood vessels, the abdominal viscera and other organs. Such investigations have become so numerous and so many well-known names are connected with them that it is impossible to mention them in detail and superfluous to report on the conclusions which have already become the common property of medical science.

Let us now consider the question whether or not an acute overstraining of the heart ever actually occurs. According to Leyden, Fraentzel and myself, we must admit of such a possibility. Still, in spite of all the histories of cases published so far the objection was raised that the heart itself had already undergone some previous change either in structure or in function and that the subsequent straining was only a determining cause for further aggravation. Although former investigations, as well as a number of old and recent cases left me hardly a doubt that a pure acute overstraining of the heart actually does occur, I considered it advisable to investigate this important question more closely. For through the solution of this problem we obtain definite conclusions regarding not only acute and chronic overstraining of the heart but also many other obscure points concerning the pathology of chronic heart diseases. On these grounds I have instituted a number of experimental investigations.

When we look at the literature we find, apart from the psychical influences which later on we shall also consider more closely, that all those causes which lead to an injury of the heart through bodily overstraining were referable to muscular actions of different kinds such as the lifting or carrying of heavy burdens, dancing, straining marches, etc. These always had in common the one fact that a dyspnea of longer or shorter duration had invariably been called forth by the most varied muscular movements.

In order to study the influence on the heart of such muscular actions as lead to dyspnea I selected wrestling which I had performed by healthy, strong men in such a manner that they alternately inhibited their movements by forcibly resisting each other or by each lifting his antagonist. I might also remark that for my experiments only such persons were selected whose clinical histories as well as local examinations showed them to be possessed of absolutely normal organs.

Before the wrestling began the heart limits and the point of the apex-beat were correctly outlined, sphygmographic curves and blood pressure registered, the position of the diaphragm and the posterior pulmonary limits located, the frequency of the respiration and of the pulse, the quality of the pulse-waves and of the heart sounds accurately determined. As long as no dyspnea appeared only an increase in the frequency of respiration and pulse were noticeable, everything else remained as before. But even a very few minutes after actual dyspnea had manifested itself the picture was changed. The heart limits were removed outward for 1 cm or more, the apex-beat was shifted visibly and perceptibly toward the axilla, the respiration was often more than doubled, the pulse pressure which at first was increased was ultimately reduced to the amount of 10-20 and more mm Hg according to the increasing severity of the dyspnea. Both tables A and B illustrate this as well as other observations made during the wrestling.

As shown (Figs 1 to 8) increase in cardiac pressure

* Read before Johns Hopkins Medical Society in Baltimore, Jefferson Medical College in Philadelphia, Medical College of Ohio and Medical Department of the University of Cincinnati.

sure manifests itself by arrhythmia, and we even notice a pause (Fig 2), once after three, again after four pulsations, this has also been mentioned by Knoll in his investigations on the alterations of the heart-beats. In the experiments of which I speak the retardation could naturally not take place on account of the strong dyspnea, and it was obviously impossible to obtain curvetracings of the pulse during the act of wrestling itself.

The relaxation of the vascular wall is very evident (Figs 3, 4, 5 and 6), as this manifests itself by a greater ascension and stronger diastole (Sommer-

lated heart is not longer able to send a sufficient quantity of blood into the arterial system even with accelerated and deeper respiration, the pulse becomes small (Fig 8), even occasionally thready, the blood pressure falls excessively (as is also evident in the pulse-tracings), or the increased intracardiac pressure which is still present after a longer period of rest continues to manifest itself by arrhythmia.

I should like to call special attention to the change in size which the heart undergoes, since this appears to me to be of great importance. I mean the dilatation

brodt) Whether we have to deal here simply with an effect of a reflex action dependent on the magnitude of the intrabronchial pressure with conditions of irritation due to deficiency of oxygen or of accumulation of carbon dioxide or with still other reflex relations, has not yet been determined.

We certainly possess in the vascular system itself a powerful factor which is able to interfere compensatorily but this is possible only to a certain extent, beyond which it is no longer able to establish an equilibrium. Thus I have often seen that the strongly di-

lated heart which takes place to the right as well as to the left and which you may be able to recognize by the diagrams¹ (Figs 14-19).

The following may be mentioned for clearer information. The heart limits in H B (which correspond also to Table A and the tracings in Figs 1-6) were determined by a renowned colleague² well versed in the art of physical diagnosis by the ordinary percussion

¹ These diagrams as well as the above tables and series of curves in all cases refer to the same two persons.

² This colleague partly made all the observations referred to in the foregoing tables or tested their accuracy.

method, then also by myself according to my late brother's method of percussion with lateral limitations. These latter limits correspond to the total cardiac boundaries as has been fully demonstrated elsewhere. The cross near the nipple marks the place of the perceptible apex-beat in all cases. You will see by the diagrams how wrestling, when once it has called forth dyspnea, is able to dilate the heart, both to the right and to the left to the amount of 1 to 2 cm and more. It is evident that this dilatation is produced only by the accumulation of blood in the cardiac cavities, a so-called congestive or passive dilatation having taken place. The ordinary method of percussion requires a cautionary measure. Then, when we percuss immediately after wrestling during the state of highest dyspnea, it may happen that we find not only no broadening of the originally determined heart limits but even a transitory narrowing of these limits, in other words, the highly inflated lungs cover up the real heart limits. But after a short

Fig 1—H B (Table A) 4 33 p m before wrestling

Fig 2—H B (Table A) 4 45 p m, after three rounds of severe wrestling

Fig 3—H B (Table A) 4 55 p m continued wrestling

Fig 4—H B (Table A) 4 56 p m renewed wrestling

Fig 5—H B (Table A) 5 22 p m after severe wrestling with tightened belt

Fig 6—H B (Table A) 5 42 p m after 20 minutes rest

lapse of time (1 to 2 minutes) the real cardiac outlines appear, this proves that the extended dullness is not caused by a retrocession of the pulmonary margins, but that it corresponds to the real limits of the dilated heart-muscle itself. When the wrestling is allowed to be continued in such a manner that dyspnea is produced along with cyanosis a further lowering of the blood pressure may be observed besides the increasing dilatation as well as a still greater frequency of pulse, respiration etc. The heart sounds, however, remained clear in both experiments only in one instance was the first sound very dull at the apex.

Since it has been proved by various authors among these ¹ Frev and Krehl² that compression of the ab-

dominal viscera with upward displacement of the diaphragm is of great influence on the amount of blood contained within the cardiac cavities, on the intracardiac pressure and on the activity of the heart in its entirety. I have instituted a second series of experiments during which a belt was fastened about the bodies of the wrestlers below the costal arch and then tightened until they experienced the sensation of great constriction. In the wrestler H B (Table A) the diaphragm was pushed upward in this way to the amount of 2 cm and in the wrestler F S (Table B) to the amount of 4 cm. Even this simple lacing of the abdomen was sufficient to call forth dyspnea and tachycardia. Especially the outward displacement of the apex-beat and the heart limits as they have been determined by my colleague and myself before the wrestling show how great an increase there was in the amount of blood in the heart cavities and how thus the clinical picture of acute dilatation had developed itself.

When the further wrestling movements were carried out energetically enough to lead to dyspnea the apex-beat was displaced very materially outward in one instance even to the extent of 5.5 cm beyond the mammillary line. Then the ventricles and especially the auricles (see heart tracings) expanded considerably, all this within a few minutes. In the first case we have again an arrhythmic pulse in the second where I had to forbid severer wrestling on account of the greater cyanosis only the smaller amount of blood in the radial

Fig 7—F S (Table B) 1 35 p m before wrestling

Fig 8—F S (Table B) 1 44 p m after 4 minutes severe wrestling and lifting

artery, along with regular rhythm, was observable. And here it was worthy of notice, that at the time of greatest heart dilatation and most marked dyspnea with cyanosis, the first sound at the apex was not accompanied with a murmur, yet it could not be called definite, being rather somewhat dull at a period when the left auricle had become extended to the amount of 3 cm and the left ventricle to 2 cm, as compared to that which was already present during the pause, the wrestler still being laced.

For more explicit data concerning the frequency of pulse and respiration, the blood pressure the heart extension etc. I must refer to the accompanying tables and diagrams.

All the symptoms gradually recede again in healthy and strong individuals. With greater tightening of the abdomen and more intense wrestling, also when the dyspnea eventually with the cyanosis and concurrently with a strongly dilated heart was very marked, it required considerable time for normal conditions to reappear, in some cases I was even able to note a few abnormalities of heart and pulse etc., after the lapse of two hours. In other cases where the group of symptoms does not develop itself so forcibly it often happens that even after a short rest entirely normal conditions are re-established.

Nowadays through sport carried on to excess we often have occasion to observe the effect of such excessive strainings on the heart and breathing is here of great importance. It was therefore of special interest to me

3. In their investigations on the Pulse they describe this fact in the following words: "When in animals with opened thorax the abdominal viscera are being pressed against the diaphragm the heart may be seen to arch itself high up during its rhythmic pauses the manometer in the artery showing a simultaneous increase of pressure. The pressure on the abdomen must be even and not too strong otherwise the great afflux of blood to the heart brings about irregular beats. In the auricles especially a degree of reptation is easily attained which deprives them of the faculty of contracting or at least allows only incomplete contractions. Ordinarily the rhythm of the ventricular beats is then also interfered with."

to study more closely the influence cycling had on the heart. To that effect I selected healthy, strong boys of the age of 13 to 15 years, who steadily bicycled, either on bad roads or on ascending grades or against strong winds. Pulse tracings showed the markedly increased frequency of the pulse, though all the boys felt well subjectively. In one case even we had arrhythmia, in another the pulse wave was very small or the elevation of elasticity scarcely recognizable. Here and there the systolic ascension amounted to only about one-third of that which the curves showed before the bicycling, the blood pressure being lowered, the heart expanded either in one or the other, or in both directions exactly in the same manner as shown in my investigations with wrestling. Here also all symptoms of heart insufficiency disappear in a short time after one single overstraining. In healthy persons this occurs sometimes after a few minutes, but when, by continued excessive sport, these symptoms frequently recur, they naturally increase in intensity and in duration, and then lead to the well-known chronic overstraining.

I also made such an investigation with a young bicyclist, 18 years old, who had a compensated mitral insufficiency. I had him run 10.6 kilometers in fifty-two

Fig 9—Cardiac neurosis before bicycling

Fig 10—Cardiac neurosis directly after bicycling

Fig 11—Cardiac neurosis after 1 minute rest.

Fig 12—Cardiac neurosis after 3 minutes rest

Fig 13—Cardiac neurosis, after 15 minutes rest.

minutes on a bad, muddy road, here a still greater dilatation was manifested both to the right and to the left, this even persisted after one-half hour's rest.

The tracings are shown (Figs 9-13) pertaining to a case of motor neurosis in a young man of 18 in whom rapid bicycling also caused a strong cardiac dilatation, a small pulse and strong palpitation, and even after fifteen minutes the sensation of cardiac fatigue had not entirely vanished.

In recent years I have also tried to investigate acute heart straining by means of the Roentgen rays. I have also succeeded, with the ordinary precautions in showing the changes of form already mentioned. This procedure is easily carried out by means of the fluorescent screen. These changes of form naturally disappear rapidly in healthy individuals.

On the ground of their orthodiagraphic investigations, Moritz and Hoffmann denied these cardiac changes due to acute overstraining. But the fact that for the purpose of carrying on their investigations they placed the subjects in a horizontal position and the uncertainty, whether this position was always exactly the same before and after the experiment make the method unreliable.

Then the fact that the overexcited heart is able to undergo strong lateral deflections in the supine position also gives the possibility of error. My experiments have been fully confirmed by the observations of Starck, Baldes, Heichelheim and Metzger regarding the influence of great bodily straining on the circulatory apparatus, the kidneys and the nervous system. The last-named authors found that in persons from 17 to 27 years old, who had previously been examined and found to be healthy, the former normal heart limits had undergone a considerable expansion after a march of 100 kilometers, within one day and with hardly a rest, a few of them had not even resorted to the use of alcohol in any form. The

Fig 14—Heart outline tracing of wrestler H. B. (Table A). Simple wrestling percussion with lateral limitation. Solid curved line heart-outline before wrestling. Broken line, heart-outline after wrestling. The x represents the perceptible apex beat.

frequency of the pulse was markedly increased, and the blood pressure considerably lowered in all the subjects of experiment, in some cases even to the amount of 25 per cent.

I trust I have proved by the above described experiments that acute overstraining of the heart really does occur, even in healthy individuals, in the latter this naturally disappears readily. In what manner and how rapidly normal conditions may again be re-established is a matter which depends essentially on the elasticity of the tissues, on the compensatory arrangements gov-

Fig 15—Same as Fig 14 only ordinary percussion

erning the vascular system, etc. Further experiments will have to determine what are the extreme limits of overexpansion of the heart, where the cardiac muscle has lost its normal capability of contraction. According to my experience, these limits seem to lie far apart in the living muscle in healthy, and especially in young, individuals. The same applies to the vasomotor compensatory appliances. With older persons when the tissues especially the muscles, have lost a considerable part of their elasticity and the vascular walls have acquired a certain degree of rigidity another condition prevails. Here one single and rather trifling overstraining may

call forth permanent deteriorations, as clinical histories illustrate. And when further pathologic changes of the tissues, and especially of the heart itself, have taken place this organ becomes exposed to the dangers of overstraining to a still higher degree.

When even a healthy heart may be injured by an acute overstraining, how much easier must this be the case in a heart-muscle which is already diseased or whose nutrition or innervation has already been interfered with by disturbances of all sorts.

I was interested in knowing whether an acute overstraining of the heart was also possible in animals. Professor Schutz, pathologic anatomist of the Veterinary College at Berlin, has made inquiries for me of several

race horse weighed $13\frac{1}{2}$ pounds, whereas the normal heart of a common horse nearly twice as heavy only shows a maximal weight of from 8 to 10 pounds. Such a hypertrophied heart-muscle might easily be able to overcome even severe overstraining without being subjected to the dangers of overexpansion.

The prognosis depends above all on the age, the degree of overstraining, the nutrition and the occupation of the patients as well as on pre-existing complications. The more elastic the tissues, the better the nutrition and the care of the patients, the quicker will the disturbances disappear and normal conditions re-establish themselves. Patients that are run down or are compelled to contin-

pathologic anatomists and veterinary surgeons. From the answers received and collated by me it is apparent that an overstraining of the heart does occur in animals, especially in horses and hunting dogs. But the physical examinations of the heart in animals meet with so many obstacles and the clinical observations are so difficult that it is easily understood why conclusions in this matter differ so much. Nevertheless so much may be gathered from all reports in question that overstraining in animals may also lead to dilatation of the heart and to

usually expose themselves to noxious influences, those also in whom valvular lesions, alterations of the heart-muscle, arteriosclerosis or other deteriorations are present, not only need a longer time for recuperation, but are also exposed to the danger that irreparable damage may be done.

As far as therapeutics are concerned it is hardly necessary to dwell on the fact that after an acute overstraining of the heart absolute rest is the first indication. Even the simple raising of the body in bed may call forth an

Fig. 17—Same as Fig. 16 only ordinary percussion.

Fig. 19—Same as Fig. 18 only wrestling with a tightened belt around abdomen.

valvular insufficiency (mostly of the tricuspid, less frequently of the mitral valve) which later on may disappear entirely. Irregular and unequal pulse and similar disturbances appeared in the same manner as in man.

So far as exact investigations have revealed rupture of the aorta was always the cause of sudden death in horses during racing, whereas an overdistention of the heart-muscle never could be noted postmortem. The latter instance seems to find an explanation in the fact that in race horses the heart-muscle shows an extraordinary degree of development, and it is certainly of interest to learn that the heart of an English full-blooded

aggravation. When an examination of the posterior parts of the lungs is required this should be made in the lateral position. Strong nutrition is always of importance.

Among medicines digitalis takes the lead; no substitute of any kind can approach it. For quieting the action of the heart the application of ice or of snuff on the anterior pectoral surface is indicated. It will hardly be possible to dispense with the use of morphia in order to alleviate the severe pains in the cardiac region, nevertheless it is advisable to be cautious in its

long continued use of large doses of this drug I have had many cases where I was able to dispense with morphin and to replace it with the application of heat. All data concerning the above I have repeatedly given in some of my writings. The use of stimulants is indicated in excessive cardiac weakness and in threatened heart failure.

When by such therapeutic means we have succeeded in saving the patient from the threatening condition and when recovery from the injuries already present has taken place, it might be advisable to resort to tonics to counteract the heart weakness, this being liable to persist for a considerable time. Here also a generous nourishing of the patient is one of the most important tasks of the physician. A rational balneologic treatment, the careful use of gymnastics, suitable exercise in the fresh air, with the avoidance of any kind of straining, all come into consideration.

I shall now give the clinical histories of a few cases bearing on the subject.

CASE 1.—Farm laborer, 24 years old, came to me in August, 1879. Excepting the measles, the patient claimed never to have had any illness, he disclaimed using spirituous liquors to excess. He was of short, compact figure and gave the impression of being a strong man with well-developed muscles and but little adipose tissue. About four hours before he came to me he had been busy lifting several heavy sheaves of wheat at a time with a pitchfork instead of only a lesser quantity, as he had been used to do. These sheaves were heavy, even to rise from the ground, and when he came to lift them higher he had to drop them on account of sudden pains in the chest, dizziness, etc. The man rested for a short time and tried to raise a smaller load, but this also was impossible, for not alone pain but palpitation of the heart and dyspnea interfered. It even forced the patient to lie down. Since the symptoms did not cease he came to me four hours later, led by a friend. It took him about two hours for a walk of about twenty to twenty-five minutes on a completely even road. Walking caused great disturbance, and only with difficulty did he succeed in mounting the stairs to my apartment. The status as follows: Facial cyanosis, marked dyspnea, small pulse. Investigation of the thorax the strong ictus cordis was very striking, apex beat could be felt outside of the mammillary line. The heart was dilated both to the right and to the left, heart sounds clear. Patient was taken home in a carriage, was given digitalis, absolute rest being enjoined and strengthening nourishment being prescribed. The following day he only complained of palpitation and the second following evening he felt perfectly well, resting quietly in bed. Objectively I found the heart action still somewhat increased, though two days later an examination again revealed normal conditions. Nevertheless, the patient was not yet able to work because any kind of straining immediately called forth palpitation and shortness of breath, so that he left for home. I never learned anything further about him.

CASE 2.—B. F., aged 15½, had always enjoyed good health and was said to have grown very rapidly of late. It was claimed that he was insufficiently nourished, even while undergoing considerable mental straining, still he never complained of being weak or not being well. For several years the patient rode a bicycle without noticing anything, in the beginning of the present year he began triecycling, which strained him considerably more. Once in the beginning of this year, having ridden more than two hours on his triecycle, he complained of an attack of dizziness and claimed to have perceived a purring noise in the region of the heart. This, however, was said to have disappeared spontaneously in a short time. A few days later he strained himself considerably by a long ride uphill on a steep and very bad road. In consequence of this not only did that purring noise in the cardiac region recur during the ride but he experienced attacks of dizziness and fainting spells and had to dismount and lean against a tree. In this condition he was found and it was only with assistance that he could find his way home. The examining physician found

a cardiac dilatation along with a systolic murmur at the apex, which, however, is said not to have been heard any more after a few days. The patient is said to have been very pale in the early stages. A few days later, when I first saw the young man, he complained only of dizziness. In the examination the cardiac hyperkinesis was very evident, the heart being still dilated to the left to the extent of 1 to 1.5 cm. With absolute rest and a strengthening diet, combined with slight resistance exercises, complete normal conditions set in within a few weeks, and with proper care he remained in good health, as was reported to me some months later.

When we consider both of these cases we find that we have to deal with persons that had always enjoyed good health. In the first of these cases one single stronger bodily straining sufficed to call forth dilatation, tachycardia, dyspnea, etc., in the second case these effects were produced by a preliminary smaller, followed soon after by a much greater strain, this being excessive for the youthful, mentally overworked and badly nourished organism. Acute overstraining of the heart takes place much more easily when the heart, through preliminary or existing alteration of the total organism, has already been disturbed in its nutrition or innervation.

CASE 3.—F. H., aged 18, was under my treatment from May 15 until June 27. Apart from measles at 8 years of age, she was always well until the previous year, when she complained of great fatigue, her physician diagnosing chlorosis. This chlorosis improved, but did not disappear entirely. She could climb hills without disturbances of any kind. Four months ago the young lady danced all night, and she admits having been tightly laced and the hall having been oppressively hot. Sometimes during dancing she had a sensation of darkness before the eyes, she experienced palpitation and shortness of breath. Nevertheless, and in spite of this group of symptoms constantly increasing in intensity, she only desisted from further dancing when she found herself compelled to drive home. The disturbances persisting, the following day the patient had to keep in bed. Her physician then noted the existence of a dilatation of the heart, and gave digitalis, also iron. The condition improved, yet walking sufficed to again bring on palpitation and shortness of breath. When I saw the patient there was still a dilatation of the left ventricle, amounting to 1.5 to 2 cm., some chlorosis was still present. With suitable baths and gymnastic treatment, a diet rich in albumin and fat, seven more weeks elapsed before normal conditions could be ascertained. Since then the patient's health remained undisturbed. She married and went through four confinements without the occurrence of any further heart trouble.

Here also we find the one solitary severe straining calls forth the same group of symptoms, the essential difference being that this one single injury of the heart—and I have seen several such cases in chlorotic girls resulting from dancing—caused disturbances that lasted several months. It certainly must be considered here that the long duration of those symptoms is to be ascribed in a great measure to the anomalous composition of the blood and, as evidenced by my experiments, to tight lacing. It is not impossible that the narrowness of the aorta so often found in chlorotic patients and which by itself increases the labors of the heart may also be considered as a factor in the quicker production of cardiac overstraining.

Of course, cases of overstraining of the heart are apt to be followed by much more serious consequences where a severe cardiac or valvular lesion already exists. Such lesions often lead to long invalidism, sometimes even to rapid dissolution.

Similarly to bodily straining strong emotional disturbances, especially fright, may also act suddenly on the heart. Although I have at my disposal many clinical

AVULSION OF THE SCALP—HAUBOLD

1129

cal histories of cases bearing on the subject, I must refrain from considering this matter any further at present, it being somewhat too far removed from my present theme. I hope, however, to be able to report on this very interesting chapter in cardiac pathology.

Clinical Notes

EXTENSIVE AVULSION OF SCALP FOLLOWED BY TETANUS WITH RECOVERY

H A HAUBOLD, M.D.

Professor in Clinical Surgery New York University and Bellevue
Hospital Medical College Surgeon to Harlem Hospital
NEW YORK CITY

The case forming the text of the following communication illustrates certain points in the treatment of conditions which, while not frequently met, may and do occur in the practice of most surgeons, and, although no new principle is submitted here, the application of accepted ones deserves mention. Following so closely on the excellent summary¹ of the treatment of tetanus with serum by Jacobson of Syracuse and Pease of Albany, a discussion of greater length in this connection would burden unnecessarily the literature and serve no useful purpose. In looking over the cases forming the basis of Jacobson's and Pease's work, it would appear that they, like all of us who compile and deduce from the publications of others, were confronted with the fact that most important details are lacking in the reports of cases submitted by the various authors, and if this contribution seems somewhat protracted it must be ascribed to my desire to escape the fault of inaccuracy which may be the outcome of an effort to be brief.

Patient—B S, aged 7, was admitted to Harlem Hospital July 16, 1906.

History—On the day of admission the patient had been knocked down by a trolley car, the fender of which pushed him along for a considerable distance, his head was ground along the rail and the scalp torn off from the left side of the skull.

Examination—This disclosed a denuded area measuring about four by five inches. The wound was symmetrically egg shaped and the periosteum corresponding to the surface indicated was also avulsed. The edges of the wound were deeply stained with the mixture of mud and grease which covered the street in the vicinity of the car rails. There were many contusions over the entire body, but at no place, other than the scalp, was the skin broken. There was considerable shock, but no evidence of cerebral involvement and no bones were broken. Reaction from shock was rapid and complete in a few hours.

Operation—The wound was cleansed and dressed in the usual manner and eight days after admission a plastic operation for repair of the scalp was made. The entire wound fortunately was within the hair area of the scalp, and permitted the application of a flap sliding method practiced by Volkmann and Messner. A study of the accompanying illustration will make the method employed sufficiently clear to render unnecessary further attempt at elucidation in the text. Mention may be properly made here however that early plastic operative effort in injuries with considerable loss of substance is a wise measure and should perhaps be more frequently performed than is usually done. More especially is this the case when ultimate cosmetic effect plays an important part in the problem presented. In this instance the flap was all taken from portions of the hairy scalp so that when healing had taken place there was no visible evidence of the

injury. In this case delay may have seemed permissible on the ground that necrosis of bone would be the result of the loss of periosteum. It is, however, to be remembered that the external table of the calvarium is supplied with nutrition by the diploë and that extensive necrosis rarely follows even severe and extensive injuries to the scalp and periosteum. Indeed, this is what happened in our case if the rapid repair of the injury is to be regarded as an indication of the absence of this complication. There were no disturbances of importance following the operation and repair seemed to progress satisfactorily.

Postoperative History—On August 3 nineteen days after receipt of the injury the patient complained of pain in the throat and inability to open the mouth fully. Up to this time the rectal temperature had been about 99.5 F and indeed showed no increase at this time but the pulse rate which had up to this been about 80 per minute rose to 98. The latter symptom we regarded as indicative of the first expression of toxemia.

The following day the mouth was firmly closed but could be opened sufficiently for the purpose of taking food. While protruding the tongue for inspection a spasm of the muscles of mastication caused the tongue to be bitten. The pulse rate remained near 100 but there was still no rise of temperature beyond that mentioned.

August 5 about forty eight hours after the first manifestations the temperature rose to 103 F and several convulsions of moderate severity occurred in rather rapid succession. The rigidity extended to the entire body and the pulse rate rose to 128 per minute. There was no disturbance of cerebration. The wound which up to this time had been healthy, lost its bright red color the granulations looked slabby and there was some secretion but no pus discharged from the raw surfaces. The line of union of the flaps remained firm however and did not at any subsequent period break down. I concluded that this was a clear case of tetanus which because of the long period of incubation (nineteen days) its gradual development and rather moderate expression would probably run a rather favorable course. On this day the house surgeon administered antitoxin in two injections of 7 cc each into the buttock and one injection of 10 cc into the spinal canal. In the latter instance about an equal amount of spinal fluid was previously withdrawn. During the night an injection of 20 cc into the spinal canal was made.

August 6 the rectal temperature was about 103 F, and the other symptoms about the same. There was rigidity and occasionally a slight general muscular spasm but the mouth could be opened for nourishment. Twenty cc of the antitoxin were injected into the spinal canal.

August 7 Dr S. J. Meltzer saw the case with me. The temperature was still about 103 F and the pulse rate 139 per minute. There was rigidity of all the muscles but no distinct opisthotonos. The mind was clear. There were some sordes on the lips and the cornea was dull. The patient at this time had received 14 cc of the antitoxin injected into the buttock and 30 cc injected into the spinal canal in four days. I had Dr Meltzer see the case with the view of determining the advisability of making injections of magnesium sulphate solution into the spinal canal.

Following the publication of Meltzer's experimentation with magnesium sulphate injections into the spinal canal for the purpose of producing anesthesia and my own observations on human beings. I like of New York City had a patient with tetanus and found that spasm was controlled almost entirely after twenty nine to thirty seven hours.

After examining our case it was concluded that there was no special indication for the use of the magnesium sulphate as spasm was not a marked symptom and that if any unfavorable outcome was to be anticipated it was probably more the result of a general enfeebling toxemia which probably interfered with metabolism and not as the outcome of a direct effect on the central nervous system. It is this latter view which perhaps rather the report of this case is a healthy one. We are inclined to look at our case from a different point of view what generally happens in our cases for a tetanus which is more in which has a different course.

of a certain land, when in a particular instance the special indication lies in another direction

Dr Meltzer suggested giving one intravenous injection of 200 cc of antitoxin on the theory that it was through the circulation that we should attack the disease. At the same time it was borne in mind that the blood already contained an antitoxin of its own creation, and that this rather heroic dose should not be repeated hastily, for fear of poisoning the patient with antitoxin. Accordingly, the patient was placed under chloroform narcosis, the median cephalic vein was exposed and 200 c.c. of the antitoxin slowly and carefully injected into the circulating fluid. That evening the rectal temperature had fallen to 99 F and the pulse was 96 per minute. The next day the patient had no spasm and the muscular system was less rigid.

August 9, forty eight hours after the intravenous injection, a slight convulsion occurred and the jaw became very rigid again. The symptoms, however, were not alarming.

August 10, three days after the intravenous injection, there was considerable rigidity and a more severe spasm. Twenty c.c. of antitoxin were injected into the spinal canal, the general condition was about the same.

August 11 the wound was dressed and appeared healthy. The patient had been very quiet, but when disturbed had a distinct opisthotonos. Twenty c.c. of antitoxin were injected into the spinal canal.

By August 14 there was still some rigidity, but no spasm for forty-eight hours. Trismus still persisted, but the general condition was favorable, the pulse was between 90 and 100 per minute and the patient took nourishment by mouth.

Volkmann's Plastic Repair of Scalp (From Tillmann's Surgery)

August 15 (the twelfth day of the disease) the patient had a convulsion and his temperature rose to 104 F, with the pulse 124. An intraspinal injection of 20 c.c. of antitoxin was given, and during the night the temperature dropped to normal.

From that time on the patient's condition gradually improved, although there was some trismus which persisted for several weeks after he was up and about. No more antitoxin was given.

Throughout the treatment the patient received 14 c.c. of antitoxin into the muscles, 100 c.c. into the spinal canal and 200 c.c. into the venous circulation.

The wound of the scalp healed completely, without untoward symptoms, beyond the unhealthy appearance alluded to, which occurred when the toxemia was perhaps at its height. This is probably ascribable to the modification of nutritive processes which occur during a toxemia.

The case may be regarded as teaching us that early plastic repair in extensive loss of substance is a wise measure, that, when muscular spasm is not a marked symptom, magnesium sulphate need not be administered and that in a certain class of cases, such as is represented in this instance, the toxin of the disease may be counteracted by the introduction of a considerable quantity of antitoxin directly into the blood current.

MODIFIED CRILE ARTERY CLAMP,

PERMITTING BOTH SCREW AND DIRECT PRESSURE
ADJUSTMENT

FREDERIC WADE HITCHINGS, S.B., M.D.
CLEVELAND

The fact that the temporary closure of blood vessels by means of instrumental compression requires careful regulation of the pressure employed is fully recognized in the idea embodied in the Crile artery clamp. In this instrument the pressure brought to bear on the vessel is regulated by means of a small thumb screw acting against a spring resistance. In order either to apply or to remove this clamp the thumb-screw must be turned several times, the number depending on the size of the vessel and the thickness of its wall. This is the antithesis of the non-adjustable spring clamp commonly used in experimental work which may be instantly applied or

Fig 1—Showing position of the jaws with the thumb screw loosened

removed by compressing it with the thumb and forefinger, but which always has the same pressure whether too strong or too weak, and which is, therefore, entirely unsuited to clinical work.

As a result of clinical observation and of work on transfusion of blood done in Dr Crile's laboratory, it occurred to me that it might be possible to construct a clamp which would combine the screw adjustment of the Crile clamp with the more rapid adjustment of the laboratory clamp. The illustrations show such a clamp as made from my model by the J. C. Ulmer Company of this city.

When the thumb-screw is loose there is lack of approximation of the jaws and hence no pressure is exerted

Fig 2—Showing the thumb screw tightened and the jaws pressed together. The arrows indicate where the pressure is applied by thumb and forefinger to release the jaws.

(Fig 1) Then if the thumb-screw be tightened pressure will be exerted by the jaws on a vessel lying between them which will vary with the extent to which the screw is made to impinge on the opposite jaw (Fig 2). Finally, when this degree of pressure is obtained, the clamp can be instantly released and removed, *without loosening the screw*, by pressing the jaws together with the thumb and forefinger at a point between the screw and the blood vessel.

When the clamp is once adjusted to a given vessel so as to exert force enough to prevent the flow of blood through it without injuring the vessel wall, it is permanently adjusted to that vessel, and may be removed and

replaced with no fear of injury or of insufficient force being exerted. This will be appreciated when, for example, an anastomosis by Carrel's method has been completed and it is desired to test the connection before finally allowing the blood to pass from vessel to vessel. It is very true that it does not take long to do this with the Crile clamp, but the shortening of an operation even by seconds is to be desired, and, whereas in replacing the Crile clamp in a hurry an inexperienced operator may apply too much pressure, this can not be done with the modified clamp if properly adjusted in the first place.

Euclid Avenue and East One Hundred and Fifth Street.

A CASE OF BILATERAL BEZOLD MASTOIDITIS FOLLOWING ANGINOUS SCARLET FEVERS*

ADOLPH O PFINGST, M.D.
LOUISVILLE, KY

The following case presents so many clinical features of interest that a full report seems justifiable.

History—When I first saw this child the following history was obtained from the family physician. A girl, aged 11, previously healthy, began, on the third or fourth day, after the onset of a well developed scarlatinal eruption, to show signs of involvement of the nasal, pharyngeal and faucal mucous membranes. Several days later the patient began to complain of pain in her left ear and on the following day both ears were discharging pus.

Examination—There was marked involvement of the mucous membrane of the upper respiratory tract, especially of the nose. The turbinates were swollen, blocking the nares. They were bathed in a yellowish pus, which had caused an excoriation of the nostrils and skin beneath. A stringy muco-pus could also be seen on the posterior pharyngeal wall. Both faucal tonsils were enlarged and partially covered with a thin grayish yellow deposit. A peculiar disagreeable odor was noticeable, emanating from the mouth and nose of the child. There was no glandular enlargement at the time. A rather thick pus was discharging from both ears through large openings in the posterior-inferior quadrant of the drums. There was no swelling of the ear canal nor over the mastoid and no tenderness over the bone. Temperature 99.5 to 100.5 F. The urine was normal. Owing to the obstruction, nasal respiration was interfered with. The enforced mouth breathing added to the discomfort of the child by causing a dryness of the buccal mucous membrane. There was some pain and considerable difficulty in deglutition.

Treatment—The mucous membranes of the nose and throat were treated by spraying with a warm carbolic solution, the nasal passages being previously opened by the use of cocaine. The tonsils were swabbed with a solution of potassium permanganate and potassium chlorate, and the ears were irrigated every two hours with a warm saline solution under low pressure. The child continued to have from one to one and a half degrees of fever. She grew weaker and more emaciated daily, but showed no other symptoms, except the enlargement of the lymphatic glands of the neck. In two weeks the swelling had reached considerable proportions. Three weeks after the beginning of the otorrhea, the patient complained for the first time of pain in and behind the right ear, the left one being unchanged. She had been growing more irritable and resented any effort to manipulate the glandular mass. Pressure over either bone did not seem to elicit pain. There was slight swelling just at the tip of the mastoid which was apparently part of the general swelling of the neck. There was no swelling over the region of the mastoid antrum and no ragging of the superior posterior wall of the external auditory canal. On the following day, however, there was decided swelling over the

lower end of the bone, so that an operation on the right side was decided on.

Operation—The conditions found were interesting. No pus was present external to the bone. The antrum was rather large and was filled with foul pus. After cleansing this and removing the neighboring diseased cells and curetting the aditus, I was about to dress the wound when, with the searcher a small rough area was detected low down on the median side of the bone cavity. The removal of this area led to several apparently healthy cells and their removal uncovered another pus cavity. When this was thoroughly exposed by the removal of overhanging ledges of bone, a small opening was found leading into the digastric fossa, from which a small quantity of pus exuded when pressure was made below the tip. The entire tip was removed and the case dressed in the usual manner. Although the only symptoms of mastoid involvement noted on the left side were slight swelling and questionable tenderness. An exploratory operation was decided on. Conditions prevailed almost identical with those on the other side. Pus had not perforated the outer table of the bone. The rather large and superficial antrum was full of pus and communicated through several smaller diseased cells with a smaller pus cavity. This in turn was found to communicate by a small opening with the digastric fossa. The mastoid tip was removed entirely on this side also and the wound treated as it was on the right side. Both wounds closed in seven and one half weeks and the drums were restored. The hearing, two months later, had returned to almost normal and the child is the picture of health, the glands in the neck having almost disappeared.

This case exemplifies the destructive nature of middle-ear abscesses complicating scarlet fever of the anginous variety. The other feature of interest was the development of the mastoid abscess with few or no symptoms. It would be impossible to determine how long the perforation into the digastric fossa had existed before the operation. The swelling and tenderness along the sterno-mastoid muscle characteristic of Bezold mastoiditis were entirely obscured by the marked glandular swelling in the neck. It is rather infrequent that the mastoid operation is demanded on both sides at once and a unique condition that both had perforated into the digastric fossa, especially in childhood when the antrum is superficial and situated high up.

A HOSPITAL SIGNAL SYSTEM

P C H PAHL, BS, MD
LOS ANGELES, CAL.

In October, 1904, I devised, for the Hospital of the Good Samaritan a signal system for calling nurses to patients, which has the following advantages:

1 Noiseless. There being no bells, the call is absolutely silent.

Fig 1—Diagram of wiring signal system Good Samaritan Hospital Los Angeles

2 Monitor board. This is in the office of the superintendent of nurses and enables this officer or her representatives to observe each call for the nurse, thus making it possible to see at a glance the number of patients desiring the services of the nurse and the length of time elapsed since the call.

* Read before the Jefferson County Medical Society Feb 17 1907

3 Lights in the corridors These are placed above the door of each patient's room, making it possible for the nurse, if she happens to be in the vicinity, to observe and answer the call without having to go to the indicator in the nurse's room

4 Lights in the rooms These are placed in such a manner that they may be readily observed by the patients, who may thus know, when attempting to signal for a nurse, whether they have been successful or not

5 Specially constructed switches These are placed in the rooms in connection with the lights and are operated by means of two cords One of these cords passes through hollow moulding substituted for ordinary picture moulding, and leaves the moulding at the side of the bed, being so arranged as to be readily grasped by the patient who pulls it, thus closing the switch and putting on the signals The other cord is placed in such a posi-

Fig 2 —Switch for signal system

tion that, while it is impossible for the patient to reach it from the bed, it is easily accessible to the nurse as she enters the room Pulling this cord restores the switch and indicates that the call has been answered

6 Signal boards The hospital is divided into five distinct departments each under the charge of a head nurse who has her headquarters in a nurse's room In each of these rooms is placed a signal board which contains the number of each patient's room in that department so that only those calls are registered.

7 Pilot lights Each department has its subkitchen in which is placed a pilot light which lights with every call in that department thus enabling the night nurse, who spends considerable time in the subkitchen preparing diets, to observe when some one is signaling On the ceiling at the intersection of the cross hall is placed

another pilot light which lights simultaneously with the one in the subkitchen, this light is visible from any point in the halls of an entire department

Figure 1 is a diagram of the wiring, *a* represents the switch (Fig 2) located in the patient's room, *b* the light in the patient's room, *d*, the light in the corridor, *e*, the light on the signal board in the nurse's room, *f*, the light on the monitor board in the office of the superintendent, *g* is a relay in the common return to the signal board in the nurse rooms Each time a call is made in that department this works buzzer *B* and pilot light *P* in multiple with it *h*, located on the monitor board, is a relay in the common return of the entire system and causes buzzer *c* to operate when a call is made from any room in the entire hospital The buzzers *B* and *c* are ordinarily not used, the pilot lights and the lights on the monitor board being sufficient. *m* is the common return and *n* the source of energy, which may be anything over fifty volts and which charges the storage battery.

Figure 2 represents a specially constructed switch, the body of which is made of wood in which the two terminals are platinum points mounted on two German silver springs The contact is made by causing a fiber cylinder to revolve on an eccentric of one-eighth of an inch

This system has been in operation over two years and has proved to be a great help in giving prompt, efficient and noiseless service Concerning the source of energy, if direct current exists in a hospital, the storage battery may be charged through a bank of incandescent lights, if only alternating current is available, however, it is necessary to install a small motor generating set with which to charge the batteries

THE INFLUENCE OF ALCOHOL AND CHLOROFORM ON PHAGOCYTOSIS IN VITRO *

GEORGE RUBIN, M.D.
CHICAGO

In a previous communication¹ I have shown how the natural defenses of the animals employed in the experiments were lowered or suspended when subjected to thorough narcotization In the several series of experiments it was noted that the narcotized animals reacted poorly to various infections artificially produced It was also shown that the recovery or death of the rabbits depended apparently on the condition of the leucocytes Narcotized rabbits when infected showed a hypoleucocytosis of various degrees, whereas the controls usually showed a pronounced leucocytosis which was followed by complete recovery or at least survival of their narcotized fellows by a considerable space of time

These phenomena suggested the possibility that the narcotics had a detrimental influence on the phagocytic function of the leucocytes It was also shown that there is a more active intraperitoneal phagocytosis of carmine granules in normal than in narcotized animals

It was now thought advisable to study the effect of narcotics on phagocytes *in vitro* The technic employed is as follows

* From the Pathological Laboratory of Rush Medical College University of Chicago

¹ Read before the Chicago Medical Society March 27 1907

¹ Influence of Alcohol Ether and Chloroform on Natural Immunity in Its Relation to Leucocytosis and Phagocytosis, Jour Infect. Dis May 30 1904

Suspensions of various bacteria, especially staphylococci, pneumococci and streptococci, are added to defibrinated dog blood containing alcohol or chloroform in varying proportions (table), the tubes are then carefully corked and placed in the incubator at 37 C for 30 to 40 minutes. Then smears are made and the bacteria in leucocytes counted and averaged. In every case control experiments were made with mixtures of normal blood and bacteria.

We see that 1 to 50 of alcohol and 1 to 200 dilutions of chloroform suspend phagocytosis *in vitro* completely. With the necessary dilutions there is an increase of phagocytosis, which, however, does not always appear to be proportional and the effect of the alcohol is practically lost at a dilution of 1 to 1000 and chloroform at 1 to 2000.

I will quote the work of Moore and Roaf² on the mode of action of the narcotics on the cells, which seems to agree with the results obtained in these as well as in my previous experiments.

From their numerous and ingenious experiments, these authors conclude that chloroform forms an unstable chemical aggregation with the proteids experimented with, and that it is carried on in the blood in such a state of combination.

Since proteids build up the protoplasm of the living cells it appears to be probable that chloroform and other anesthetics must form similar combinations with protoplasm, and that anesthesia is due to the formation of such compounds which limit the chemical activities of the protoplasm. The compounds are unstable and remain formed only so long as the pressure of the anesthetic in the solution is maintained.

The action of the various anesthetics occurs not only with nerve cells but with ciliated and other epithelial cells with muscle cells of all types, with bacteria, with imbr and with unicellular organisms.

In all these varied types of living cells activity decreases alike with increasing dose of the anesthetic, and with sufficient concentration all signs of life become obliterated.

Hence the action of the anesthetic must be due to some change brought about in the only material which is uniformly present in all these types of cells, that is the cell protoplasm.

We can easily see from the foregoing explanations how the phagocytic function of the leucocytes may be suspended or entirely destroyed by the toxic agents in question.

It was shown in the previous communication how alcohol ether and chloroform alike affected the natural defenses of rabbits to various infections. The prominent

role the leucocytes appeared to play in connection with their immunity was also pointed out.

With the experiments *in vitro* recorded in this paper together with the excellent work of Moore and Roaf we can conceive more clearly the influence of anesthetics on cell life in general and particularly on those cells which interest us most at this time—the phagocytes—both the fixed and circulating. The influence of the agents in question on the opsonins has not been studied so far. The behavior of the phagocytes in my experiments with inert substances (carmin granules) proves that so far as the above experiments are concerned the opsonins seem to play no rôle at all.

In conclusion I desire to thank Professor Hektoen for his invaluable suggestions and courtesies.

DEATH FROM ACETANILID POISONING

A. I. SMEDLEY, M.D.
HAMILTON, OHIO

Patient—F. H. H. male aged about 29, height 5 feet 11 in., weight about 190 pounds.

History—When I returned to my house at 12 30 p. m., I found that the patient had been waiting for me about thirty minutes. During that time he had vomited twice and had asked for smelling salts, as he felt very ill. I found him very weak and cyanotic with a slow pulse and slow and shallow respiration. He stated that he had an intense headache and asked for something to relieve it. From the symptoms and general appearance of the patient I suspected acetanilid poisoning and asked him how many headache powders he had taken. He stated that he had taken three between 9 and 12 o'clock and that his headache became worse after each dose.

Treatment and Result—I administered 1/20 gr. strychnin nitrate with 1/60 gr. atropin sulphate and told the patient to let me know how he felt in thirty minutes. The man left my house and walked home—about two blocks. As I did not hear from him in thirty minutes I left for my office and as soon as I got there I received a telephone message asking me to go to him at once as he seemed worse. I found him weaker and more cyanotic, with cold extremities and a pinched look. The respirations were almost imperceptible. The man scarcely breathed unless roused and told to breathe deep. At 2 p. m. I gave 1/20 gr. strychnin nitrate 1/50 gr. digitalin, and 1/100 gr. nitroglycerin hypodermically. The man was given a hot pack, the feet elevated and cold applied to the head. He was also given 20 drops of spirits of camphor in a teaspoonful of whisky every half hour.

I called Dr. F. M. Barden in consultation about 4 p. m. At that time the man was in a severe convulsion and very cyanotic. The pulse was very weak. The convulsion lasted about ten minutes when edema of the lungs developed and death ensued at once.

Postmortem—Autopsy the following day showed edema of the lungs, dilatation of the heart and congestion of the kidneys—a condition of acute cloudy swelling. All other organs were normal. There were about twelve ounces of urine in the bladder and examination showed marked traces of albumin.

The man's wife stated that he had not been feeling well for three or four days and it is possible I think that he had suffered from grip which left an acute nephritis.

The powders in question were put up by a local druggist who informed me that each powder contained acetanilid 5 grains, citrate of caffeine 1 grain and sodium bicarbonate 3 grains. The amount of acetanilid taken by the patient therefore was only 15 grains. I think the powder caused nausea and vomiting within an hour after he had taken them and his headache was very

EFFICIENCY IN HEALTH ADMINISTRATION

It is a significant sign of the times that the New York Academy of Medicine has established a section on Public Health. In an address¹ delivered at the opening of this section Dr George A Soper discusses the sanitary engineering problems of water supply and sewage disposal for New York City and certain other matters of general interest. He points out that authentic sanitary information is now desired by the public, but that it is difficult to obtain it, in the first place, because great universities have neglected to teach in an adequate manner sanitary science or preventive medicine, and, secondly, because physicians do not fully recognize their importance as sanitary teachers. For these reasons, a vast amount of technical knowledge has not been popularized sufficiently and public opinion has not been directed to the proper consideration of many topics relating to public health. One of the functions of the new section, therefore, must be to assimilate data and to help in the more rapid diffusion of knowledge in sanitary matters.

Unquestionably there is much of truth in what Dr Soper says concerning the failure of universities and physicians to teach sanitary knowledge. It should be remembered, however, that a great deal, indeed a remarkably great deal, of efficient work in this very line has been done and is being done by institutions of various kinds as well as by physicians individually. The reason, or, rather, one highly important reason, why the public has not profited to the fullest extent from the available sanitary knowledge seems to lie in the general failure under our political system to secure as public officials men with the necessary special training and expert knowledge. This, of course, is true not only with respect to health officers of various kinds, but to an equal degree with respect to many other departments of public service.

In our political life it is unfortunately the usual thing that men are installed for a brief period in important positions for the efficient exercise of the duties of which they are fitted neither by experience and training nor special natural gifts. One consequence is that while the established routine work of various offices may be carried on in a fairly satisfactory yet often crude way, new and progressive policies in harmony with changing con-

ditions and increasing knowledge are not introduced so promptly as they should be and the necessities of the future and of more or less unexpected emergencies are left without adequate provision. It is only too true, as Soper says, that "thus far, in the history of sanitation, the great strides of progress have usually resulted from emergencies. Unfortunately this method of progress still prevails to a large extent through the country." In evidence of the truth of this statement it is necessary to mention only the sudden changes in water supplies so often precipitated by avoidable and predictable epidemics of typhoid fever.

Progress in other branches of public service also commonly seems to proceed from analogous causes. The better way, and the way more likely to be followed when departments of public service are managed by men with special training and expert knowledge, is to make the schemes necessary for improvement while there is ample time for careful investigation and preparation. Hence, public opinion and the attention of those with appointive powers should be continuously directed toward the vital importance of special, technical qualifications in our public services. This applies with especial emphasis to the departments charged with public sanitation, because in their particular case prevention is the peculiar function, and the conditions to be prevented must be foreseen and removed so far as possible before they result in disease. "The highest skill and wisdom are none too great to enlist" in the practical application of technical knowledge derived from diverse sources in order to prevent disease and to render human life pleasant and healthful. The city of New York is able to furnish us a fortunate example in the way of efficiency in health administration.

TYPHOID FEVER IN THE DISTRICT OF COLUMBIA

There have been few greater surprises to sanitarians than the singular prevalence of typhoid fever during the past year in the District of Columbia. In the autumn of 1905 a modern sand filter, designed by and constructed under the supervision of some of the most eminent sanitary engineers in this country, was put in operation in the city of Washington. The particular mode of treatment adapted for the water of the Potomac River, the character of the plant and the details of operation had been long and thoroughly discussed and studied by qualified experts. It was confidently expected, therefore, that the operation of this filter would be followed by the same results that have been observed in Lawrence, Mass., Albany, N. Y., and other places in this country where a filtration plant of similar character has been installed. Surprise and consternation resulted when, in July, 1906, the number of cases of typhoid fever in Washington suddenly increased so that the disease was regarded as prevailing in epidemic form. Since the Potomac River water had long been known to be polluted, and since sand filtration elsewhere had

been shown to purify effectively waters of a similar character, the recurrence of the disease under the greatly improved conditions was a matter of keen disappointment to both the medical profession and the public at large.

In view of these rather extraordinary conditions, a commission was appointed by the Surgeon-General of the Public Health and Marine-Hospital Service, comprising a number of capable officers of the Hygienic Laboratory and the Public Health and Marine-Hospital Service. In fact, during the summer of 1906 almost the entire force of the Hygienic Laboratory concentrated its energies on this problem.

The investigation included a sanitary survey of the Potomac watershed, a searching epidemiologic study of the 866 cases of the disease occurring in the District of Columbia between June 1 and October 31, 1906, daily chemical and bacteriologic examinations of the public water supply, a special study of the pumps, wells and springs in the District and also of the bottled waters on sale in Washington, inspection of dairies and laboratory examinations of the milk supply, inspection of ice factories and analyses of the water from which the ice was made as well as of the ice itself. Special attention was directed to the communicability of the disease from person to person by direct or indirect contact. The agency of flies and other insects as carriers of infection was a subject of special investigation.

As a result of this comprehensive study certain conclusions and recommendations were arrived at by the board of commissioners, which will soon be printed in a bulletin of the Hygienic Laboratory, an advance copy of which has been sent to us through the courtesy of Surgeon-General Wyman. Only a few of the findings of the commission can be mentioned here. The commission notes in the first place that the prevalence of typhoid fever in the District of Columbia during the period covered by their investigation was due to several causes, about 15 per cent of the cases being imported, 10 per cent being attributed to infected milk and 6 per cent to contact, leaving 69 per cent unaccounted for. Particularly interesting, in connection with the contact cases, are the observations on the inefficiency of measures for the disinfection of the discharges from the bodies of typhoid fever patients. The report of the commission is definite and emphatic on this point. "The destruction of the infection as it leaves the body is the most important measure to prevent the spread of typhoid fever. In our opinion it is the duty of the attendant physician to see that these measures are effectively carried out. It is evident from the above figures that this important prophylactic measure is not carried out as it should be in the District of Columbia. If this condition of affairs can not be corrected then we should recommend its enforcement by legislative enactments."

We have more than once had occasion to call attention to this important subject. There is no reason to think that in this respect physicians of the District of Colum-

bia are less insistent than physicians of other cities in having the details of prophylactic disinfection carried out. The warnings of the commission can not be too often repeated and insisted on. There can be no doubt that rigorous disinfection would diminish enormously the transmission of typhoid fever, although in view of the recent developments regarding bacilli carriers it is certainly not fair to assume that the disease would completely disappear if known cases are properly disinfected and cared for.

Another thoroughly investigated question was the milk problem and the report of the commission on this subject is explicit and well considered. Although the evidence that was secured indicated that not more than 10 per cent of the cases studied were due to infected milk, the commission does not hesitate to state that "While the present outbreak of typhoid fever is by no means wholly attributable to milk, the wonder is, judging from our observations of the milk business in the District of Columbia, that more illness and disease is not spread through this medium."

One of the most interesting sections of the report discusses the probable relation of the public water supply to the recent epidemic, and a number of arguments in favor of the view that the filtered Potomac water played an important part in the dissemination of typhoid fever are marshaled in an impressive manner. On the other hand, reasons in favor of the view that the Potomac water had little, if any, share in the dissemination of typhoid fever in Washington are likewise considered. This perplexing matter is summed up finally as follows: "In view of the foregoing, it is evident that at present it is not possible to present satisfactory proof of the part played by the Potomac River water in the spread of typhoid fever in the District of Columbia, therefore the commission reserves final decision on this subject until investigations now in progress at the Hygienic Laboratory, have been completed."

While this verdict leaves the country in suspense as to the actual situation in Washington, it seems to venture about as far as is warranted by the evidence presented in this report, and it certainly has not been proved that the filtered water supply was responsible for the recent epidemic. The weight of evidence that has been accumulated in connection with the installation of successful filtration plants in other cities would seem rather to throw the burden of proof on the other side. Some stress has been laid in the report on the seasonal incidence of typhoid fever in Washington, the disease being here as in many other places particularly a summer infection. The coincidence of the maximum amount of typhoid fever with the prevalence of the house fly has not been overlooked but we believe that even more significance might be attributed to this point. On the other hand the hypothesis of an increased susceptibility to typhoid fever in warm weather has something to recommend it, especially in view of the seasonal increase of infantile diarrhea. Such is

ceptibility doubtless plays a rôle Inconclusive as the report is, it must certainly take rank as one of the most thorough and extensive studies of an outbreak of typhoid fever, not due to water pollution, that has ever been made That the Washington situation is still a puzzling one is in no wise the fault of the authors of this important document, but is rather due to our incomplete epidemiologic knowledge

CATERPILLAR RASHES

The introduction of the brown-tail moth, *Porthesia chrysorrhæa*, into Massachusetts and New Hampshire, and its almost certain spread into neighboring states, needs comment at this particular time, as summer is approaching, and the peculiar skin eruption resulting from contact with the insect has not yet become widely known in the United States The results of the action of certain poisonous plants of the *Rhus* family are widely known both by the laity and the profession, but even physicians have not yet become acquainted with the irritant effects produced by these moths and their caterpillars

The knowledge of skin rashes due to caterpillars dates back to the time of the ancients, in modern times the matter has been commented on mainly by the entomologists, who, in making their collections, have occasionally been poisoned In recent years the attention given to nature study, even in the primary schools, has rendered the collection of caterpillars and moths by children common, and the bright colors of some of the poisonous varieties have added to the collector's zest In places, too, as recently in the states named, the brown-tail moth, one of the poisonous species, has flourished exceedingly, and opportunities for poisoning have consequently increased This will be better understood when it is explained that actual contact with the caterpillar or moth is not necessary, and that underclothes dried in the open in the neighborhood of infected trees may become the receptacles of the poison

Clinically, the poisoning appears in two forms, as Tyzzer¹ has pointed out in his interesting study If the poisoning results from direct contact, as when a caterpillar falls on the neck and is brushed off, a marked local dermatitis appears, confluent in character, and characterized by reddening and thickening of the skin with the formation of papules and vesicles Children who handle caterpillars and then, as often happens, rub the eyes and face with the infected hands, develop more discrete lesions often associated with conjunctivitis When underclothes become infected, too, the lesions are more discrete, and in the form of papules which change to vesicles

That the hairs of the caterpillar, or to be more exact the barbed or "netting" hairs, are the poisoning agent

has been known for some time The transmission of the irritant by these hairs, even when dried and detached from the insect, explains the occurrence of the rash after wearing underclothes dried in the open, and the occasional occurrence of the dermatitis after merely walking in the neighborhood of thickly infested trees The older writers were of the opinion that the irritant quality of the hairs was purely mechanical and due to their barbed shape, but the careful studies of Tyzzer have shown that this is an erroneous view A definite toxic substance of an irritating character is contained within the netting hairs, it can be destroyed by heat, is soluble in water at certain temperatures, and produces peculiar and characteristic changes in red blood corpuscles brought into contact with hairs which contain it The intensity of the lesions produced by the introduction of the barbed hairs into the skin depends to a certain extent on the number of hairs introduced, the character of the lesion is always the same, consisting in a necrosis of the epidermal cells about the hairs, the formation of microscopic vesicles about the site of injury, and the production of inflammatory changes around the vessels of the corium As in most toxic diseases there are marked individual variations in susceptibility, and in caterpillar dermatitis, just as in rhus poisoning, some are very susceptible, and others apparently immune

JUDICIOUS LUNG GYMNASTICS

Some pertinent criticisms of the chest-swelling drill so dear to English army traditions have recently been expressed by Lieut Col F A Davy, M D,¹ who finds the "setting-up" drill, by which the military bearing is attained, to be wrong in theory and injurious in practice This army surgeon asserts that rigid shoulders and protruding chests interfere with the normal course of the circulation The exercises which bring about these results really invalid many men, they do not benefit the defective, but, on the contrary, often harm even the strongest "Holding the breath" is condemned as disturbing the balance between the respiratory and circulatory systems and as being directly in contravention of physical laws Dr Davy declares that soldiers would be stronger and healthier if they were permitted to abandon the attitude they have worked so hard to attain, and to carry themselves much as the man on the street does He finds that increased chest measure is often gained at the cost of motility and vital capacity, the young recruit much too often presents on examination a rapidly beating heart, a shortness of breath and a very decided discomfort

It is common to find men who have been athletes during their college days to be suffering from hypertrophied and even chronically dilated hearts, with blowing murmurs especially pronounced at the carotids These men pant easily and tire in a most distressing

¹ Jour of Med. Research March 1907 abstracted in this issue of THE JOURNAL p 1460

¹ Davy (F A) Army Medical Dept Report for 1905 Lancet Feb 16 1907

way on slight exertion. They are not nearly so "fit" as men who have lived normally, without attempting to "build muscle" by means of inordinately severe exercises. Woods Hutchinson tells us that, according to statistics, athletes are two and one-half times as liable to cardiac diseases, 60 per cent more liable to kidney diseases, and 25 per cent more liable to die of the three main infectious diseases of adult life than the average man. No doubt the same will be found true of those workmen who most frequently subject their bodies to heavy and exhausting strain.

For phthisical individuals lung gymnastics should certainly be interdicted in the presence of a decidedly subnormal temperature, or when there is fever (certainly when 100 degrees is reached), in cavity formation, in all acute processes, in evidently advanced disease, in tuberculous laryngitis, in rapid pulse and tumultuous heart, in fatigue or dyspnea on exertion, in hemoptysis or blood-streaked sputum, in pathologic blood conditions, in recent pleuritis, in other intercurrent or complicating diseases, when the weight is much below the normal for the patient's height, when strength and vitality are much reduced. It must be always remembered that in phthisis the organism is on the verge of bankruptcy, and may easily collapse with immediately fatal issue when the imposed exercises are excessive or beyond its strength. Of course, before prescribing "deep breathing, with the lips closed," the upper air passages should be examined for hypertrophies, exostoses or other obstructions to respiration.

THE DIAGNOSTIC DOSE OF TUBERCULIN

It is an unfortunate fact that the manner in which tuberculin first came into use led to a revulsion of feeling against it on the part of many physicians. Once introduced, and if it had not been that Koch's hand was forced its introduction doubtless would have been delayed, it was hailed with acclamation and used without discrimination, with the natural result that its good features were overshadowed by the resulting catastrophes. Notwithstanding the manner in which the majority of physicians have since held aloof from it many of the lung specialists have used it continuously for both diagnostic and therapeutic purposes. Its value in diagnosis can be readily understood when it is stated that from 50 to 80 per cent of the patients who enter the German sanatoria for pulmonary tuberculosis have no tubercle bacilli in their sputum. Many of them have very slight physical signs of tuberculosis and in many of these cases it is doubtful whether the signs represent an active process or are the result of healed tuberculosis or a pneumokoniotic process. The necessity of a correct diagnosis in these and other doubtful cases is especially great from the patient's standpoint for it may mean the difference between freedom and a long sojourn in an institution.

One of the most serious errors which attended the administration of tuberculin in the early days after its introduction related to dosage. There can be little doubt that too large amounts were given, with resulting severe local and general reactions and positive harm to the patient. Wright's work on the opsonic index has exposed the fallacy, so far as the therapeutic use of tuberculin is concerned. Whether or not we have been giving too large doses for diagnostic purposes is still under discussion. At the Tuberculosis Congress in Paris in 1905 Lowenstein and Kauffmann claimed that the dosage used to-day was much too large, and that 2/10 milligram repeated three or four times at intervals of a few days was sufficient. The old Koch method was to begin with one milligram and gradually increase to ten.

The relative value of the different doses has been tested by Roepke¹ on over 700 patients. He soon came to the conclusion that the dose advocated by Lowenstein was much too small, as it entirely failed to produce reactions in most of the patients with early lung signs on whom it was tested. Roepke also concluded that the doses used in the old Koch method were unnecessarily large, and that it was not entirely the question of dose but also the matter of sudden increase in dose which decided the reaction. He found 2/10 milligram was enough for an initial dose and recommends giving five times this dose in a few days, i. e., one milligram, and a few days later, if no reaction has occurred, five times the second dose. This gives results equally as good as the old Koch method and with only half the maximum dose. The tuberculin reaction is unquestionably of great value in diagnosis, and it is to be hoped that the profession at large will recognize that the procedure is not dangerous if properly carried out.

GRADUATE MEDICAL STUDY

The need of graduate technical instruction has been apparent for some years. The introduction of new methods of diagnosis and treatment requiring the use of new instruments and apparatus has rendered the education of the physicians, as given at the medical schools of ten to twenty years ago entirely inadequate for the needs of the present day. This need has been but imperfectly supplied by the graduate school and to meet it more perfectly there has been developed in Prussia and extended over the German Empire a system which is in striking contrast with those formerly in vogue. In the first place it is designed to furnish what is essentially free instruction to all physicians. A small registration fee is charged for some courses amounting only to two or three dollars. Secondly, instead of concentrating the instruction in large cities it is aimed to carry it to the less populous centers where the physicians from the smaller towns and villages can attend without having to travel far. The course usually is about two years long and the distance being small the cost for board and

home once during the course and could be called in case of emergency without great loss of time. Thirdly, the courses are for the most part didactic and technical but not clinical. The reason for this is that while the necessary apparatus for demonstrations and practical laboratory instruction can be found in the smaller places, or can be easily transported, and the specialist may go without inconvenience to the smaller town to deliver a lecture, clinical material can be obtained in sufficient abundance only in the large city. The system is managed by a central committee located in Berlin and is brought to public notice by a special journal¹ which appears twice a month. In addition a center for the direction of the movement has been provided in a building, known as the Kaiserin Friedrich House, devoted to the purposes of such technical instruction. This central building serves as a central office for information and direction of the movement and as a storehouse for collections of specimens, etc., to be loaned gratis to the various local centers where courses are to be given. It also provides laboratories for technical instruction, lecture rooms for didactic but not clinical lectures, and it contains, besides, a permanent exhibition of instruments and apparatus for the use of physicians where the visitor may see and examine the newest and best devices and determine what he needs. The plan has been successful from the first so that about one-third of the physicians of the empire have taken part in the courses. The subjects include in some cases a review of the entire medical curriculum, while in others special work is done in medical chemistry, bacteriology, electricity, Roentgenology, physical therapeutics, etc. There appear to be many features of this scheme for post-graduate professional education that are applicable to American conditions. The busy physician who can not get away to take a course in some large city is usually within easy reach of some college town where laboratory facilities could be provided and where he could go and return to his home at night. Specialists who could expect to receive patronage from a group of village or country physicians would doubtless give demonstrations of methods of instrumentation with which the practitioner should be familiar. County societies could easily arrange short courses with the help of a central organization which could take advantage of the resources of the universities whose aid in carrying out such a plan could confidently be relied on.

HOSPITAL MANAGEMENT IN ST. LOUIS

St. Louis is presenting a gratifying spectacle of a united profession attacking one of the important medico-political problems, that of hospital management, and endeavoring to free the municipal hospitals from the interference and domination of practical politicians. In 1905, according to the *St. Louis Medical Review*, the eleven medical societies of St. Louis, embracing all branches of medicine and all therapeutic creeds, formed a joint medical council for the purpose of effecting reforms in public medical matters. The first subject chosen was hospital management, and the council found

certain defects which it traces to the fact that under the present system all appointees, from the hospital superintendent down to the most humble employé, are subjects of political patronage. The results, which are unsatisfactory under a good administration, become chaos when the administration is a bad one. To remedy these conditions the council proposes: 1, separation of the health department from the hospital department, 2, vesting of control over the hospitals in a board of trustees, similar to the present school board, and elected by the people, 3, provision for an executive superintendent or steward, 4, provision for a medical staff of experienced physicians appointed by the board of trustees for a term of years, 5, provision for an interne body of physicians, to be chosen on the basis of competitive examination conducted by the staff, such internes to be responsible to and under guidance of the medical staff. These proposals have been modified in a bill to be presented to the municipal assembly providing for submission to the people of the necessary amendments to the city charter. The council has received assurances of support from over a dozen of the most intelligent representative bodies of citizens, and apparently the only evidence of lack of unanimity in the good work is the attitude of the politically constituted health board. This body, although it has formerly busied itself in legislative matters for the good of the public, suddenly discovered that "its functions are purely administrative, it had no jurisdiction whatever over matters of this kind, and that, under the circumstances, nothing could be gained by a further discussion of the subject." That hospitals should be taken out of politics needs no argument. They are semi-educational institutions which have important functions in the way of clinical teaching and research work in addition to the care of the sick, and they need the peace and permanence of administration essential to the carrying out of definite policies. It is to be hoped that the efforts of the St. Louis physicians will be successful and will serve as an example and encouragement to other communities, showing what physicians can accomplish for the public welfare by united effort, and pointing to the ideals of management of medical institutions, toward which all ought to strive.

THE PRESERVATION OF MOSQUITOES DURING WINTER

It has long been known that mosquitoes hibernate during winter, and are thus preserved from season to season. In view of recent experiments conducted by Passed Assistant Surgeon Francis¹ of the Public Health and Marine-Hospital Service, it appears very probable that the *Stegomyia calopus* is also preserved in another way, thus in two ways being able to survive a southern winter. Francis collected eggs of this genus of mosquito in Mobile, Ala., Aug. 16, 1906, and preserved them in the dry state at practically outdoor temperatures until Feb. 27, 1907, a period of six and one-half months. Water was then added, and the eggs developed into adult mosquitoes, these in turn laid eggs which hatched into larvae, thus completing the life cycle. The length of

¹ *Zeitschr. f. aerztl. Fortbildung*

¹ *Public Health Reports* xxii No. 14

time stegomyia eggs can withstand desiccation has been variously stated Theobald mentions two months² Reed and Carroll³ kept them for ninety days without destroying their fertility The latter observers also noted that freezing did not destroy their viability Observations regarding the habits of this mosquito are of much importance, since it is responsible for the transmission of yellow fever, and Francis' studies are of value to sanitarians, as they readily account for the propagation of this species in our southern latitudes Francis also reports having found this species during every month of the year—an important point which indicates the necessity of continued efforts looking to their destruction In view of our present knowledge it is fortunate that the statements of Marchoux and Simond⁴ regarding the hereditary transmission of the virus of yellow fever have yielded only negative results in the hands of other workers

DEATH OF THE EDITOR OF THE LANCET

We are called on this week to chronicle the death of Thomas H Wakley, F.R.C.S., Eng., senior editor of the London *Lancet* His death removes from the journalistic field one of its great men, one who has helped to build up a great paper, and one whose personality had its influence on every department of the business under his direction The *Lancet's* work in the analysis of foods and medicines has been a most valuable contribution to progress We can speak no better eulogy of Mr Wakley than to quote from the "In Memoriam" of the *Lancet*, April 13 "He was bold in exposing evils of a general or public character, hearty in helping forward every public advancement, zealous to make the *Lancet* the first chronicler of any new and promising progress in the science and art of medicine, and especially anxious to make it useful in works which were of a sound philanthropical and beneficent nature"

PURE MILK OR BLENDED WHISKY

As we go to press we learn that the substitute pure food bill now pending before the Illinois Legislature has been advanced to third reading in the House This bill is a makeshift substitute for a carefully drawn and thoughtfully considered bill formulated by the state Pure Food Commission The original bill contained practically the same provisions as the national Food and Drugs Act, modified for state purposes It also contained special provisions for a pure milk supply and regulated conditions in the dairy farms as well as methods of transportation and delivery The substitute bill contains none of these provisions It is stated in the daily press that the chairman of the committee on manufactures induced the speaker of the House to omit these provisions on the ground that they would interfere with the butter milk and cheese business It has also been stated that the Flgin Board of Trade, which practically controls the butter market, was influential in bringing about this change The position of the business men seems to be that cleanliness is expensive and will lay too heavy a tax on the business and that the people of the state in order to protect the profits of the business should take the consequences in the shape of dirty milk

The *Chicago Daily News* charges that a lobbyist, who is also interested in blended whisky, played an important part in the substitution of the emasculated bill for the original It might be well for the medical profession in Illinois to ascertain whether the pure food bill now pending is for the benefit of the people or was drawn in the interests of dirty milk and blended whisky

Medical News

ILLINOIS

Epidemic Diseases—Three new cases of scarlet fever were discovered in Rockford, April 15 all on the West Side The center of infection from which the cases originated has not yet been discovered—An epidemic of measles is reported at the Soldiers Orphans' Home, Bloomington, where 45 cases and 4 deaths have occurred

Personal—Dr David C Kretzer after three years duty with the Philippine constabulary has resigned and returned to his home in Decatur—Dr Frank H Gardner has been elected president Dr Henry S Bennett, vice president and Thomas J Lamping secretary treasurer, of the Moline City Hospital—Dr John W Dryer, Aurora while bicycling was thrown to the pavement by a runaway horse and suffered severe cuts and contusions of the face and body—Dr Charles C Rayburn, Kewanee, has decided to go to the West for the benefit of his health—Dr John J Rigg, Mount Pulaski, will leave in a short time for Europe

Chicago

Personal—Dr Frank Billings and daughter returned from Europe April 18—Dr L Harrison Mettler has resigned from the faculty of the Chicago Clinical School

City Physician Reports—Dr Joseph T Todd, city physician, has submitted a report of the work of his department for the fiscal year There were 2705 visits and inspections made, 87 of which were for alcoholism Aid was rendered to 104 injured persons

Visiting Nurses—The annual report of the secretary of the Visiting Nurses' Association of Chicago shows that the year has been successful A number of bequests have been received and the association aided in the establishment of the Edwards Tuberculosis Fresh Air Sanatorium at Naperville The question of a central home for the nurses is now being considered

Iroquois Memorial Hospital Plans—The committee of the Iroquois Memorial Hospital Association has outlined to the president of the Cook County board the plan of the association for a memorial emergency hospital in the downtown district The committee proposes to lease the ground at 13 and 45 La Salle Street at an annual rental of \$5000 and to erect thereon a three story building to cost about \$30000 The committee asks the county to pay for the lease of the land and states that the hospital association will pay for the building

Reduced Death Rate—During the week ended April 20 100 fewer deaths were reported than during the preceding week The deaths for the week numbered 617 equivalent to an annual death rate of 15.26 per 1000 Pneumonia still headed the death list with 103 followed by consumption with 81 heart diseases with 60 Bright's disease with 47 acute intestinal diseases with 42 violence (including suicide) with 28 and cancer with 27 Of the communicable diseases diphtheria caused 12 deaths scarlet fever and whooping cough each 11 measles 7 typhoid fever 4 and influenza 3

INDIANA

Gives Hospital Site—Dr George W Pence Greener has offered to the Putnam County Hospital Association a building site for a hospital on the condition that the hospital shall bear his name that it shall be used for hospital purposes only that it shall be used only by regular practitioners and that the association shall raise a fund sufficient for its erection and maintenance

Personal—Dr Nelson D Praxton Indiana director of the physicians in the employ of the Isthmian Canal Commission has returned to his duty in Panama after a vacation in Ecuador and the Columbian republic—Dr Lyman T Law's, Hometown was shot and seriously injured in the lower part of his home by a man believed to be insane—Dr T H Gray

⁴ Ann de l'Institut Pasteur xx p 16

Davis, Richmond, has resigned as a member of the State Board of Health, to take effect May 1

March Mortality and Morbidity—The deaths for March amounted to 3,502, or 272 more than were reported in March, 1906. During the month measles was prevalent in 82 of the 92 counties of the state, and 15 deaths were reported. Influenza was still more prevalent, 204 deaths being reported, while only 46 deaths were reported in the corresponding week of 1906. The order of prevalence of diseases was as follows: Influenza, tonsillitis, rheumatism, measles, pneumonia, bronchitis, diphtheria, scarlet fever, pleuritis, intermittent and remittent fever, typhoid fever, diarrhea, smallpox, whooping cough, inflammation of the bowels, erysipelas, dysentery, typho malarial fever, cerebrospinal meningitis, puerperal fever, cholera morbus and cholera infantum. The deaths from pneumonia numbered 575, or 106 more than for the corresponding month of last year. There was an increase also of 6 deaths from cancer and 54 from violence. Tuberculosis caused 431 deaths. Smallpox was reported from 20 counties with no deaths, in the corresponding month of last year 97 cases were reported from 11 counties, with no deaths. There were 210 cases of typhoid fever reported, with 40 deaths, from 33 counties, in the corresponding month of last year there were 211 cases, with 34 deaths, from 62 counties.

KANSAS

Addition to Medical College—An addition is proposed to the medical building of Kansas University at Rosedale, to cost \$45,000.

State Society Meeting—The annual meeting of the Kansas Medical Society will be held on the third floor of the Banking Trust building, Seventh Street and Minnesota Avenue, Kansas City, Kan., March 7 to 9.

Personal—Dr. John C. Rudolph, Lawrence, has been appointed health officer of Douglas County, vice Dr. Hiram T. Jones, resigned.—The following health officers of Salina County have been appointed: Drs. Howard N. Moses, Salina, Louis O. Nordstrom, Assaria, Enos R. Cheney, Gypsum, and Wilber E. Fowler, Brookville.—Dr. Josiah P. Lewis, Topeka, is seriously ill at his home.

College Graduation—The class of 1907, numbering 15, was graduated April 11 from the Kansas Medical College. Dr. H. B. Ward, Lincoln, Neb., dean of the College of Medicine of the University of Nebraska, delivered the general address, and Theodore W. Peers the faculty address. Dr. William L. Lind, sav. dean of the college, was master of ceremonies, and the diplomas were presented by the president of the institution.

KENTUCKY

Epidemic of Meningitis—It is reported that 20 more deaths from cerebrospinal meningitis have occurred in Harlan County during the last month.

Library Donated—Dr. Joseph M. Mathews, Louisville, has donated his personal medical library, consisting of 800 volumes, to the local public library.

Personal—It is announced that the resignation of Dr. James W. Hill, superintendent of the Institution for the Education of Feeble Minded Children, Frankfort, has been received and accepted by the state board of control. Dr. Louis H. Mulligan, assistant superintendent of the Eastern Kentucky Asylum for the Insane, has been called to Frankfort by the state board of control to take charge of the institution until a superintendent can be elected.—Dr. David T. Stuart, Paducah, has arrived in Shanghai.—Dr. William A. Keller, Louisville, city physician for the West End, is reported to be critically ill at his home with typhoid fever.

LOUISIANA

War on Mosquitoes—The New Orleans city board of health has begun an investigation of mosquitoes not the *Stegomyia calopus* but the ordinary mosquitoes which are a source of discomfort during the entire year, and their extermination has been systematically planned.

Medical Department of State University—At a meeting of the executive committee of the board of supervisors of the Louisiana State University it was announced that progress had been made and that the medical department would be inaugurated in New Orleans this fall under most favorable circumstances.

Havoc Wrought by Cyclone—The cyclone which swept over the Gulf states April 6 wrecked several buildings of the Louisiana Insane Asylum, Jackson. The damage to the institution was about \$100,000 and four female patients were killed. The governor of the state immediately sent tents and cots for

the temporary housing of the inmates of the asylum, and measures have been taken for rebuilding.

Personal—The office of Dr. Mark L. Johnson, Hackley, was burned to the ground, with a loss of \$1,100 and no insurance.—Dr. James M. Batchelor, house surgeon at Charity Hospital, and Dr. Waldemar T. Richards, New Orleans, were severely injured in an automobile accident, March 30.—Drs. C. Milo Brady, New Orleans, medical inspector for the State Board of Health, and Henry A. Veazie, shipping inspector for New Orleans, have concluded their service for the state. Dr. Brady will enter on private practice and Dr. Veazie has been appointed to the U. S. P. H. and M. H. Service.

Sanitary Conference—A conference of the parish and municipal health officers has been called for May 2, 3 and 4 at Opelousas, under the auspices of the Louisiana State Board of Health, to consider important questions of public health and hygiene. One of the most important matters to come before the conference is the outlining of a bill to be presented before the next legislature, giving parish health officers reasonable authority and fair compensation. In addition to health officers the commercial bodies of the state and women's clubs have been invited to send delegates to the conference.

MAINE

Grenfell in Portland—Dr. Wilfred Grenfell spoke on his mission to the deep sea fishermen of Labrador, at St. Luke's Cathedral, Portland, April 14.

Personal—Dr. G. Gilmore Weld was inaugurated as mayor of Old Town, March 25.—Dr. Walter L. Hunt, Bangor, has succeeded to the practice of Dr. Frederick W. Mitchell, Island Falls. Dr. Mitchell, after pursuing postgraduate work in Baltimore, will locate in Houlton.

Contagious Diseases—It is reported that diphtheria is prevalent in the Capsuic and Rangeley Lake regions. Many lumber camps are in quarantine. The Franklin County Board of Health is cooperating with the State Board of Health to check the spread of the disease.—At Westbrook 25 cases of scarlet fever have been reported to the board of health, and on this account the public schools have been closed.

MASSACHUSETTS

Feeble-Minded Institution Site Bought—Valuable properties in the town of Wrenham have been purchased by the state for the establishment of an institution for the feeble minded. About 500 acres have been secured.

Bill to Lower Milk Standard Defeated—A bill introduced into the senate to lower the standard of the milk supply in the state was defeated. Dr. Charles Harrington, Boston, secretary of the State Board of Health, opposed the bill.

Personal—Dr. Henry William Miller, Taunton, has been made psychopathologist in the Cook County Institutions, Dunming, Ill.—Dr. S. Alphonse Daudeln, who sailed for Europe on *La Savoie*, April 18, was given a dinner at Worcester, April 16, in honor of his appointment as high commissioner to the Maritime Exposition, Bordeaux, France.

Management Approved—The investigation of the State Hospital for Dipsomaniacs, Foxboro, has resulted in a report by the governor's executive council, approving the management. It is advised, however, that an age limit should be established and that there should be a separate institution for the care of hopeless inebriates without criminal records. With these two changes, the present institution will be much more efficient in accomplishing the purposes for which it was established.

MINNESOTA

Few County Health Boards—Dr. Henry M. Bracken, secretary of the State Board of Health, states that only 30 out of the 85 counties in Minnesota have appointed county boards of health, as required by law.

Proposed Fund for Sanatorium—A request is to be made to the legislature at this session for the creation of a fund of \$50,000 to be used for the maintenance of the State Sanatorium for Consumptives near Walker. One wing of the main building is nearly completed and about 25 acres of land, on which cottages may be constructed have been cleared. The building already erected is almost ready for occupancy at a cost of more than \$200,000.

Personal—Dr. and Mrs. Charles P. Robbins, Winona, have returned after eight months abroad.—Dr. O. Edward Linjer has been elected city physician of Minneapolis, vice Dr. Emil H. Beckman, resigned.—Dr. Charles Malchow, Minneapolis, imprisoned on a charge of sending improper literature through the mails was released from the state penitentiary, March 30.—Dr. John B. Dunn has been elected chairman of the

board of health of St Cloud—Dr Thomas H. Wimer, Marshall, is reported to be critically ill—Dr Adolph O. Bjelland has been appointed health officer of Mankato.

MISSOURI.

Brown Gets Loving-Cup.—On April 11 the staff of the St Louis City Hospital presented a silver loving cup to Dr John Young Brown, who recently resigned from the superintendency.

Hydrophobia Ward Opened.—The hydrophobia ward of the St Louis City Hospital was opened April 12. St Louis is now thoroughly equipped for treating patients afflicted with rabies.

Smallpox.—Five cases of smallpox have occurred at the Young Women's Christian Association boarding house, Kansas City—The health officer of Greene County reports 25 cases of smallpox at Republic.

Senior Student Dies.—Joseph H. Magana, a native of Mexico and a senior student at the St Louis College of Physicians and Surgeons, died at Jefferson Hospital in that city, April 4, after an operation for appendicitis.

Tuberculosis Prevention.—The St Louis Society for the Prevention of Tuberculosis has been incorporated with the aim of disseminating, by means of lectures and literature, information concerning tuberculosis, how it spreads and how it may be combated. The association expects to formulate plans for a tent sanitarium for the treatment of tuberculosis.

Physician Fined.—Dr F. W. Lanoix, Kansas City, was fined \$25 April 14, on the charge of practicing medicine without a license. A complaint was made that he had entered into the practice of medicine and surgery in the city without having filed a copy of his certificate with the State Board of Health, and that he was not authorized by the board to practice medicine and surgery.

Personal.—Dr Emmett P. North has been appointed to succeed the late Dr Augustus Von Liew Brokaw as superintendent of the United Street Railways Company, St Louis—Dr Edmund A. Donelan, St Joseph, for several years president of the board of education, has been re-elected medical supervisor of public schools by the board—Dr John F. Chandler, Forest City, has been elected secretary of the Holt County Medical Society, vice Dr Samuel W. Aiken, Oregon, removed from the county.

MONTANA.

State Board Election.—The newly formed State Board of Health met in Helena, perfected its organization and elected Dr William Tracey, Helena, president, and Dr Thomas D. Tuttle, Billings, secretary.

Personal.—Dr William T. Scott, Great Falls, has resigned as secretary of the Cascade Medical Society, and has gone to Europe—Dr Robert L. Stokes, Lewiston, has moved to Washington, D. C.—Dr Thomas H. Pleasants, Lewiston, formerly of Helena, is reported to be dangerously ill with pneumonia in Chicago.

Elections.—The Silver Bow County Medical Society, at its annual meeting held in Butte, elected the following officers: President, Dr Josiah S. Hammond, vice president, Dr Creswell T. Pigot, secretary, Dr Grace W. Cahoon, treasurer, Dr McCormick Smetters, and executive committee Drs Josiah S. Hammond, Laura L. Keisker, Richard C. Monahan and Thos. J. Murray, all of Butte—The Madison County Medical Society, at its annual meeting, held in Virginia City April 5, elected Dr Cay F. Tidman, Ennis, president, Dr Limer L. Sutherland, Sheridan, vice president, Dr Edgar I. Bradley, Virginia City, secretary treasurer, and Drs Tidman and Bradley delegates to the State Medical Association.

NEBRASKA.

Bill for Tuberculosis Hospital Passed.—A bill introduced by Representative Howard providing for the establishment of a tuberculosis hospital at Hastings and appropriating \$25,000 to pay for the site and construction, has passed the House of Representatives.

Personal.—Dr Joseph W. Bourne, South Auburn, has been appointed physician for the west half of Nehama County, including Auburn and Dr W. W. Frazier, Nehama, physician for the east half of the county, including the poor farm—Dr Allen T. Hill, Lyons, while making a professional call, was attacked by highwaymen and lost \$15 and a hypodermic syringe.

Official Organ of State Society.—The *Western Medical Review* recently transferred from Lincoln to Omaha has been made the official organ of the state medical society. At a meeting April 11 the following directors were elected: Drs

August F. Jonas, Frank E. Coulter, Henry L. Akin, Henry L. Burrell, and George H. Bicknell. On the following day the board of directors met and elected Dr August F. Jones, president, Dr Henry L. Akin, secretary, and Dr Archibald L. Muirhead, editor.

NEVADA.

Personal.—Dr John A. Ascher Sparks has been appointed physician of Washoe County—Dr William L. Berry, Carson City, has been re-elected physician of the Nevada state prison.

Hospital Notes.—The local Catholic parish of Reno will undertake the construction of a hospital, to be placed in charge of the Dominican Sisters, and to cost \$70,000—The Miners' Union Wonder, has started a movement toward the erection of a hospital in the camp.

NEW HAMPSHIRE.

Loss by Fire.—A recent fire at Newport destroyed the house of Dr J. Leavitt Cain, with a loss of more than \$4,000.

Epidemic of Influenza.—The physicians of Nashua report that there are at least 200 cases of influenza, affecting especially the eves, in Nashua and vicinity.

New Hospital Building.—Laconia is to have a new hospital the erection of which will be begun in a short time. The structure will be of brick with stone trimmings. The administration building will be the first to be erected.

College Graduation.—At the annual graduation of Dartmouth Medical School, Hanover, March 29, a class of 11 received diplomas. Dr William H. Keith, Lancaster, delivered the address to the graduates and diplomas were presented by Dr William T. Smith, Hanover, dean of the medical school.

NEW YORK.

New District Society Organized.—The Fifth District Branch of the State Medical Society has just been organized, including the counties of Oswego, Onondaga, Lewis, Oneida, Herkimer and Jefferson. The first meeting will be held in October.

Academy Anniversary.—The fifty-fifth anniversary of the Elmira Academy of Medicine was celebrated by a dinner at the Elmira City Club, April 4. Dr Charles H. Trazier, dean of the Medical Department of the University of Pennsylvania, read a paper on "Surgical Complications in Typhoid which Affect the Abdominal Viscera."

Personal.—Dr Charles W. Pilgrim, Poughkeepsie, has decided to retain the position of president of the State Board of Lunacy Commissioners—Dr Henry W. Carpenter, for 55 years a practitioner of Oneida, suffered a cerebral hemorrhage recently—Dr Edward H. Hutton, Corning, is seriously ill at the Corning Hospital with pneumonia.

Deaths from Respiratory Diseases.—This class of diseases was mainly responsible for an increase in the February death rate. The death rate was 18.8 per 1,000 for the month of February, compared with 18 for the same month last year. In the entire state there was a decrease of 228 deaths from pneumonia as compared with February, 1906, but an increase of 974 from other acute respiratory diseases. In New York City there were 463 fewer deaths from pneumonia, but an increase of 668 from other acute respiratory diseases. The mortality from influenza was also high, 618 deaths being recorded from this cause. There was also a slight increase in the number of deaths from these diseases during February as compared with January. Deaths from external causes increased from 518 in February, 1906 to 715 in February, 1907.

Matters Before the Legislature.—Representatives of humane societies have made a strong appeal for a favorable report on the Francis bill which restricts vivisection to such experiments as shall be performed under the supervision of the state. A delegation of New York surgeons appeared in opposition to the bill. They argued that the bill might bring about experimentation on human beings and check the advance of science. Such a bill would close the laboratories in the medical colleges and discourage surgery. After a debate characterized by considerable bitterness the senate on April 18 advanced to the order of final passage. The public health committee's bill substituting a single medical examining board for the three boards now representing the allopathic, homeopathic and eclectic schools of medicine. Dr D. B. St. John Roo says in regard to the passage of this bill through the senate that a ridiculous climax in medical legislation is evidently near. The following paragraphs have crept into the bill somewhere along its course:

Where the application be for a license to practice osteopathy the applicant shall produce evidence that he has studied osteopathy not less than three years, including three full years of study, not less than nine months in three different calendar years, in a college of osteopathy maintaining at the time a standard of

tory to the regents. After 1910 the applicant for a license to practice under this act shall produce evidence that he has studied not less than four years, including four satisfactory courses of not less than seven months each in four different calendar years, in a college maintaining at the time a standard satisfactory to the regents.

It is further provided that any person who shall be actively engaged in the practice of osteopathy in the State of New York on the date of the passage of this act and who is a graduate in good standing of a school or college of osteopathy within the United States which at the time of his or her graduation required a course of study of two years or longer including the subjects of anatomy, physiology, pathology, hygiene, chemistry, obstetrics, diagnosis and the theory and practice of osteopathy, with actual attendance of not less than twenty months, which facts shall be shown by his or her diploma and affidavit shall on application and payment of \$10.00 be granted without examination a license to practice osteopathy provided application for such license be made within six months after the passage of this act. A license to practice osteopathy shall not permit the holder thereof to administer drugs or perform surgery with a knife. Licenses to practice osteopathy shall be recorded in accordance with the provisions of this act and the word osteopath shall be included in such registration and such license shall entitle the holder thereof to the use of the degree D. O. or doctor of osteopathy.

The New York milk committee and the committee on the prevention of tuberculosis of the charity organization have decided to cooperate in seeking to get a law passed this session to stamp out tuberculosis in the cattle of the state. It is thought that with not less than \$200,000 to be spent by the state department of agriculture in testing and condemning cattle, a long step would be taken in securing milk free from tuberculosis germs. A bill to increase the compensation to be paid to farmers for condemned cattle has led the committee to believe that some law can be passed providing for a strict quarantine on all cattle coming into the state and that all cattle shall be tuberculin tested. The proposed bill, in addition to this, would forbid the sale of all milk handled by a person having an infectious disease and would make it illegal for any one who has been exposed to such disease to be employed in a dairy farm until such person had received a clean bill of health from the local health authorities.

New York City

Personal—Dr Charles H. Peck, the senior attending surgeon to the French Hospital of this city, has recently received from the French government through the minister of public instruction and fine arts the decoration of "Officier de l'Instruction Publique."

Object to Tuberculosis Hospital—The taxpayers of Richmond, Staten Island, have asked for a permanent instead of the temporary injunction obtained last December, restraining the charities commissioner from building a tuberculosis sanatorium on Staten Island.

Contagious Diseases—There were reported to the sanitary bureau for the week ended April 13, 469 cases of measles, with 3 deaths, 466 cases of tuberculosis, with 200 deaths, 438 cases of scarlet fever, with 14 deaths, 341 cases of diphtheria, with 39 deaths, 80 cases of typhoid fever, with 8 deaths, 55 cases of whooping cough with 7 deaths, 17 cases of cerebrospinal meningitis, with 15 deaths, 69 cases of varicella and one case of smallpox, a total of 1,036 cases and 289 deaths.

Contagious Diseases and the Bellevue Staff—The records of Bellevue Hospital for the past three months show that six members of the house staff have been stricken with diphtheria, three with scarlet fever and one with blood poisoning, which may result in the loss of a finger. During the same time 13 nurses have been stricken with diphtheria or scarlet fever while on duty. This would indicate that the hospital interne in New York takes more risk of death than a fireman, and more chances in one day than a policeman takes in a year.

Hospital Conference—The annual hospital conference of the City of New York was held April 24 at the Academy of Medicine. Dr S. S. Coldwater gave an address on "Dispensary Ideals with the Plan for a Dispensary Reform Through the Adoption of Restricted Numbers." The address dealt with the literature of dispensary abuse, the New York dispensary law, the newer dispensary ideals, the work of dispensary nursing association, the district work of New York dispensaries, the opinions of prominent dispensary workers and the authors own proposed program.

City Has Low Death Rate—The lowest death rate for the year was reported for the week ended April 13. It was 18.47 per 1,000 or 1,517 deaths as compared with 20.35 per 1,000 or 1,620 deaths for the corresponding week of last year. The highest number of deaths thus far this year was for the week ended January 5 when there were 1,721 deaths. The number of deaths from typhoid fever for last week was 8 as compared with 10 in the corresponding week of last year. The number of cases reported last week was 51, which is encour-

aging as compared with the 120 cases reported two weeks previously.

Anniversary of German Dispensary—On the occasion of the fiftieth anniversary of the German Dispensary, Dr Charles H. Jaeger founded three prizes, to be known as the Marie Jaeger Memorial Prizes. The prizes are for medical essays and are of \$100, \$75 and \$50, respectively. The competition is to be open to members and collaborators of the German Dispensary and to members of the house staff of the hospital. The prizes are to be awarded December 31 of each year. The essays are to be based on cases occurring in the service of the hospital and dispensary. The object is to stimulate research and promote scientific study.

Watershed Dangers—The department of health has given out the report of a conference at which Dr Darlington, health commissioner, John H. O'Brien, the water commissioner, and Dr Eugene H. Porter, state health commissioner, were present to consider conditions existing at Mount Kisco and Katonah, on the Croton watershed, which have been threatening the pollution of the water supply of this city. The report says that the State Department of Health has been endeavoring to have a sewer system constructed at Mount Kisco. The village authorities maintained under the law that New York City should pay for the sewer system and sewer disposal. The corporation counsel of New York City has advised that this city is not liable. The matter has been placed in the hands of the attorney general, who will shortly render an opinion. Commissioner Porter has written Dr Darlington urging the construction of a filtration plant as being the safe way in which the water supply can be protected. Experiments in infiltration are being made, as it is estimated that a plant will cost the city \$10,000, 000, which is more than well can be afforded unless it is assured that the plan adopted will be entirely satisfactory.

OHIO

Joint Commencement—On May 8 the sixtieth anniversary of Starling Medical College will be celebrated. At this time the joint commencement of the newly combined Starling Medical College and Ohio State University will be held. Seventy-two applicants for degrees will be presented.

Lectures on Nervous and Mental Diseases—Dr Frank W. Harmon, superintendent of Longview Hospital for the Insane, Carthage, has instituted a course of lectures from the immense mass of material on nervous and mental diseases collected in the institutions. These lectures, delivered on Mondays from 4 to 5 p. m., are by Dr Philip Zenner, Frank W. Langdon, Herman H. Hoppe and David I. Wolfstein. The lectures are free and are intended for practitioners and senior students.

In the Hands of the Law—"Dr" T. P. Hanley, Kinsman, arrested for practicing medicine without a license was found guilty and fined \$200 and costs. Dr James G. Ambrose, Dayton, charged with performing a criminal operation, is reported to have been found guilty and released on bail, pending the disposition of a motion for a new trial. "Dr" C. R. Greiner of Toledo, charged with practicing medicine without a license, is said to have been found guilty. He has taken an appeal.

Personal—Dr A. W. Foeltmeyer has been appointed resident physician to the Cincinnati City Hospital. Dr Samuel S. Wilson Xema, has returned from Europe. Dr J. Thomas Elliott, East Liverpool, goes to Johns Hopkins University for two years postgraduate work, June 1. Dr Oliver H. Pinney, Norwood, will leave for Assonet, Central Africa about the 1st of June. Dr Adam B. Howard, formerly superintendent of the Cleveland City Hospital, will leave April 29 for a trip to Great Britain. Dr Frank McCafferty, Columbus, has been appointed a member of the local board of public safety. Dr Harry E. Welch, health officer of Youngstown, is seriously ill with septicemia.

PENNSYLVANIA.

Decrease of Typhoid—Superintendent Edwards of the Pittsburgh Bureau of Health, reports that during March 144 cases of typhoid were reported while during March, 1906, more than 400 cases occurred.

Bills Passed—On April 17 the senate passed the bill legalizing the practice of osteopathy in the state, providing for a State Board of Osteopathic Examiners and allowing them a member in the State Medical Council. On the same day the Senate Appropriations Committee reported favorably the bill appropriating \$20,000 to the York Hospital.

Expenditure for State Hospital—At a special meeting of the Board of Trustees of the State Hospital for the Insane, Norristown, held April 10, it was decided to expend the

\$412,000 appropriated by the legislature as follows: Home for men nurses, \$75,000, convalescent home for men, \$60,000, chapel and amusement, \$50,000, bard extension and storage house, \$15,000, two ward buildings, \$200,000, and enlargement of refectories, \$30,000.

Personal—Dr Martha S. Everitt has removed from Scranton to York.—Dr Jonathan L. Forwood, Chester, completed his first half century of practice of medicine and was the guest of honor at a banquet at the Keystone Club in that city April 8.—Dr Milton A. Hengst has been elected president and treasurer of the Birdsboro Board of Health.—Dr John W. Beck, Peckville, who has been seriously ill with peritonitis, is reported to be convalescent.—Dr B. H. Warren, state dairy and food commissioner, has resigned.—Dr William T. English, Pittsburg, has returned from an extended tour in the South.—Dr Joseph K. Weaver, Norris town, surgeon general of Pennsylvania, was recently presented with a loving cup by the officers and teachers of the Baptist Sunday School, of which he has been superintendent for 25 years.—Dr Charles W. McConnell, Altoona, is seriously ill as the result of a shock from a heavy current of electricity, April 6.—Dr Henry H. Riegel, Catasauqua, will finish half a century of practice of medicine early next month.—Dr Frederick H. Evans, Chester, has been elected advisory physician of the Eddystone Board of Health.—Dr Samuel G. Dixon, State Health Commissioner, Harrisburg, has been elected honorary member of the Academy of Physics and Chemistry, Palermo, Italy, and has been awarded a medal of the first class for scientific and humanitarian merit.

Philadelphia

School of Anatomy Competition—On April 15, Dr W. Wallace Fritz announced the result of the competitive examination of the Philadelphia School of Anatomy. The best thesis was presented by Dr James F. Kelly of Bridgeport, Conn., who received as a prize a case of surgical instruments.

Reception to Gilder—A reception was given by the Medical Club of Philadelphia April 19, to Richard Watson Gilder, who made a short address, in which he urged the establishment of an institute for the investigation of faith cure and other treatments not recognized by the medical profession.

Presentation to Resident Physician—The physicians and nurses of the University Hospital gave an informal dinner to Dr George Morris Piersoll, chief resident of the hospital, April 19. On April 20 he completed his two years' service and a silver loving cup was given him as a testimonial.

Donation of Land to Hospital—Mr Felix Isman has donated to the Jewish Hospital Association a triangular piece of ground at the corner of Tenth Street and Clarkson Avenue adjoining the property owned by the hospital. This conveyance enables the Hospital Association to square the lines of the property which it owns.

Personal—Dr Frank H. Gatchell, prominent in medical circles for many years, is reported to be critically ill as the result of a fall on ice coated steps five weeks ago.—Dr J. William White has been selected by the directors of the Pennsylvania System as advisory surgeon for the company. He will have the general supervision of the medical department of the system and its hospitals and equipment will be organized in accordance with his views.—Dr John H. Gibbon has been elected associate professor of surgery in Jefferson Medical College, vice Dr John Hill Brinton, deceased.

Society to Support Dispensary—At a meeting held April 16 a new society was formed whose object is to solicit funds for the support of the Southeastern Dispensary of the University of Pennsylvania. Dr Barton Cooke Hirst, who as professor of obstetrics is by arrangement, honorary president of the society and the active chairman of the board of directors presided. An appeal is made to the Alumni and friends of the university to support this project aside from further increasing the efficiency of the obstetrical department and the benefit to medical students. The inhabitants of the southeastern section of the city are most deserving poor, and the dispensary has been of great service to them.

Cerebrospinal Meningitis—On April 14 Dr Jay T. Schamberg addressed the medical inspectors of the Bureau of Health on measures to be taken to detect cases of spinal meningitis and to prevent the spread of the disease. Dr Schamberg declared there is no need for public alarm over the number of cases of spinal meningitis. He regards it as unlikely that the present ratio of cases will keep up. In the week ended April 20 there were 36 new cases of cerebrospinal meningitis reported to the Bureau of Health. This is an increase of 8 over the number reported for the previous week. Director

Clay of the Department of Public Safety has issued orders to flush the streets in the districts where the disease exists.

Semi Centennial of Society—The Pathological Society of Philadelphia, one of the oldest, if not the oldest of its kind in America, will celebrate its semi centennial May 10 and 11. On the first day addresses will be delivered by Dr Frederick G. Novy, Ann Arbor, on "The Role of Protozoa in Pathology," by Dr Simon Flexner, Rockefeller Institute, New York, on "The Newer Pathology," and by Dr Alonzo L. Taylor of the University of California, San Francisco, on "The Dynamic Point of View in Pathology." In the afternoon a commemorative meeting will be held in the Pennsylvania Hospital where the first meeting of the society took place in 1857. At this session Dr William Osler, Regius Professor of Medicine in Oxford University, will deliver an address on "Pathology and Practice." A dinner will be given in the evening and the next day will be devoted to an exhibition meeting of interest to pathologists, clinicians and surgeons.

GENERAL

Carroll Made Doctor of Laws—The Board of Regents of the University of Nebraska has recommended that the degree of Doctor of Laws be conferred on Major James Carroll, surgeon, U. S. Army, at the annual commencement exercises in June.

Data on Diet and Endurance Wanted—Prof. Irving Fisher of Yale University desires us to announce that he is engaged in collecting all available statistics and facts bearing on the question of diet in relation to endurance. Physicians who have had experience with more than one system of diet whether personally or through patients are invited to address him at 400 Prospect Street, New Haven, Conn. He will then submit definite questions.

Railway Surgeons Meet—At the annual meeting of the physicians of the Cotton Belt Railway System, held in Texarkana, Texas, April 8, the following officers were elected: President, Dr C. M. Ludlow, Hillsboro, Texas, vice presidents, Drs William H. Blythe, Mount Pleasant, Texas, Amos W. Troupe, Pine Bluff, Ark., J. W. Beall, Malden, Mo., and Oscar Dowling, Shreveport, La., and secretary treasurer, Dr H. H. Smiley, Texarkana, Texas.

Control of Typhoid Fever in the Army—Medical officers of the Army have become more and more impressed each year with the importance of contact infection as a means of spread of typhoid fever among troops. This fact was clearly shown in the report of the typhoid fever board of 1898. Of 1,609 cases which they were able to definitely locate in particular tents, 62.80 per cent were connectable directly or indirectly. Of recent years the attention of medical officers has been frequently called to the importance of the patient as the source of infection and recently they have been instructed that for practical purposes the disease must be considered contagious and patients affected with it isolated as far as practicable in separate wards. This point together with early recognition and careful attention to detail in the disinfection of all discharges as they leave the patient are emphasized in the directions for the control of the disease.

Education Conference—The third annual conference of the Council on Medical Education of the American Medical Association will be held in the Auditorium Hotel, Chicago, Monday, April 29, 1907. Committees will report on the advisability of allowing a year's advanced standing in the medical school to graduates of colleges of arts and sciences and also on details as to the requirement, in addition to a four year high school education, of a year to be devoted to physics, chemistry, biology and one language as a prerequisite to the study of medicine. The following papers are also announced:

Conditions Controlling General and Medical Education in the South—Chancellor J. H. Kirkland of Vanderbilt University, Nashville, Tenn.

Inspection of Preliminary Credentials by an Officer of the State Examining Board—Dr Dudley Salt, President, California State Examining Board, San Francisco.

What Constitutes a Creditable Medical College?—Dr Howard J. Rogers, First Assistant Commissioner of Education, Albany, N. Y.

Methods of Conducting the State Board Examinations—Dr Bruce D. Hurler, Secretary, Michigan State Board of Health, Detroit.

A Plan for a License Examination in Two Parts—Dr W. T. Means, Chairman, Judicial Council, Association of American Medical Colleges.

National Health Department—Steps have been taken by the Committee of One Hundred, appointed in June by the American Association for the Advancement of Science toward stirring up the public sentiment in favor of federal supervision of the public health. It is probable that a new department or through an already existing twenty member committee will be organized at a meeting and an executive committee will be appointed.

MEDICAL NEWS

be vested with the prosecution of the movement. Other meetings will soon be held and local committees to cooperate with the central committee will be named. If this scheme is successful it will include bureaus on infant hygiene, school sanitation, pure food, registration of physicians, drugs, drugists and drug manufacturers, and on public and private institutions of correction, detention and residence. There would also be a bureau of national sewage and one of organic disease.

Tuberculosis Association to Meet—The third annual meeting of the National Association for the Study and Prevention of Tuberculosis will be held at the New Willard Hotel, Washington, D C, May 6 to 8, 1907. The secretary is Mr. Irvington Farrand, 105 East Twenty second Street, New York. The general meeting will open at 11 30 a m, Monday, at an address by the president, Dr Herman M Biggs. Dr Lawrence F Flick will make a report on the International Congress on Tuberculosis, 1908. In the evening Dr Herman M Biggs will speak on "Compulsory Notification and Registration on Tuberculosis" Discussion will follow. On Tuesday, "The Campaign Against Tuberculosis in the United States" is chairman, and Christopher Easton, Mt Vernon, N Y, secretary, will meet Monday at 4 p m and Tuesday at 11 a m. The subjects announced are:

Tuberculosis Classes and Day Camps Dr Joseph H Pratt, Boston
Country Treatment of City Cages Dr B H Waters New York
Working Program for a Small City Dr Oscar H Rogers
Schools and Tuberculosis Dr John H Lowman Cleveland
Factory Inspection for Tuberculosis Dr Frank T Fulton Providence

The Clinical and Climatological Section, of which Dr George Dock, Ann Arbor, Mich, is chairman and Dr Joseph Walsh Philadelphia, secretary, will meet Tuesday at 4 p m and Wednesday at 11 30 a m. In addition to the reports of the committees on clinical nomenclature, medication and mixed infection, the following papers are announced:

Some Experience with Tuberculin L Rosenberg Bedford Station N Y
The Varieties of Tuberculin Dr Woods Hutchinson Redlands Cal
Phagocytosis etc in Sputum as a Measure of Resistance in Tuberculosis Dr Albert H Allen Saranac Lake N Y
Examination of Feces as a Means of Diagnosis in Tuberculosis Dr Myer Solis Cohen Philadelphia

The Pathological and Bacteriological Section, of which Dr Frank F Westbrook, Minneapolis, is chairman, and Dr S Marx White, Minneapolis, is secretary, will meet Tuesday at 11 a m and Wednesday at 9 30 a m. The following subjects are announced:

Split Products of the Tubercle Bacillus and Their Effects on Animals Dr Victor C Vaughan Ann Arbor
Further Notes on the Technique of the Tuberculo-Opsonic Test Drs Hugh W Kinghorn and David C Twichell Saranac Lake N Y
Homologous Bacteria as a Vaccine in Tuberculosis (Preliminary Report) Dr Albert H Allen Saranac Lake N Y
Report from the Rockefeller Institute Dr Simon Flexner New York
The Pleura Dr W B Stanton Philadelphia
Acute Villous Tuberculosis without Tubercle Formation Dr A S Warthin Ann Arbor
Occult Blood Findings in Tuberculosis Dr H R M Landis Philadelphia

The Section on Tuberculosis in Children, of which Dr Thomas M Rotch, Boston, is chairman and Dr Samuel S Adams Washington secretary, will meet Monday at 2 p m. The following papers are announced:

The Living Pathology of Tuberculosis of the Bones in Early Life Dr Thomas Morgan Rotch Boston
Recent Advances in the Knowledge of Tuberculosis in Children Dr Charles Hunter Dunn Boston
The Present Status of the Transmissibility of Tuberculosis in Children as Illustrated by Infants and Young Children Dr Henry L K Shaw Albany
Tuberculosis of the Cervical Nodes and Infections from the Tonsils Dr Fred T Murphy Boston
Are Tuberculous Infants and Children in the First Five Years of Life Pliable to be Sources of Infection? Dr Samuel S Adams Washington
The Surgical Section of which Dr William S Halsted Baltimore is chairman and Dr Hugh H Young, Baltimore secretary, will meet Tuesday Mar 7 at 9 30 a m. The following papers are announced:
Present Status of the Opsonic Theory and the Treatment of Tuberculosis Dr Rufus I Cole Baltimore
The Treatment of Bone and Joint Tuberculosis by Hyperthermia Dr Schmieden Bonn Germany
The Use of the X Ray in the Treatment of Certain Forms of Tuberculosis Dr Henry K Pancoast Philadelphia

FOREIGN

JOUR. A M A
April 27 1907

International First-Aid Congress—The German "Samariterbund" has called an international conference of all leaders in the matter of first aid to the injured on sea and land. The congress will convene at Frankfurt a M, in May, 1898. Mayor Adickes of Frankfurt is the chairman of the executive committee.

Institute for Puericulture as Memorial to Budin—A committee has been formed in France to collect funds to found a practical school of puericulture to bear the name of P Budin, an enlargement of his idea of "nursing consultations." Senator P Strauss is chairman of the committee, and the publishing house of O Doin & Co, 8 Place de l'Odéon, Paris, has been appointed treasurer of the fund.

Moebius Endowment—The friends of the late P J Moebius of Leipsic, whose death was mentioned in THE JOURNAL on page 541, issue an appeal for subscriptions to endow a Moebius prize to perpetuate his name. The appeal is signed by Professor Ediger and others. Dr Curt Reinhardt, Lessingstrasse, Leipsic, Germany, is the treasurer of the fund. The intention is to found an annual prize for the best work on neurology or psychiatry, one year to be given for original works sent in competition, the next year for the best work published anywhere during the preceding two years.

Approaching International Congress of Hygiene—The Fourteenth International Congress of Hygiene is to be held at Berlin, September 23 29, as already announced. These congresses have been held in various countries, but this is the first time that Germany has been the host, and elaborate preparations are under way to add to the historic interest and practical benefits of the congress. The Imperial Board of Health is getting out a *Festschrift*, as also the Imperial Board of Statistics. The Prussian department of public instruction is also at work on a *Festschrift*, to be dedicated to the congress, and the city of Berlin is getting up a fourth.

International Medical Association for Suppression of War—The annual meeting of this society, which has its headquarters at Paris, was held March 22, with the organizer and president of the association, Dr J A Rivière, in the chair. Nine resolutions were adopted by the convention, among them one congratulating the president of the United States and the presidents of Mexico and Guatemala for their offer of arbitration to Honduras and Nicaragua, and congratulating the latter countries for their acceptance of the offer. Another resolution congratulated "le grand journaliste, Stead pour sa superbe campagne pacifique auprès des gouvernants." The last resolution was a message of congratulation to Dr Senolo Murakami for his success in organizing a "Peace Association" in Japan. The meeting is described in the *Progrès Médical* for April 6.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, April 13, 1907

Lord Lister's Eightieth Birthday
Lord Lister celebrated his eightieth birthday at his residence 12 Park Crescent Portland Place. Many telegrams from all parts of the country and abroad reached him. His apartments were decorated with floral offerings. He received several deputations who presented addresses of bouquet was attached a card bearing a congratulatory message. He received high appreciation of his work. To each president of the Lister Institute of Preventive Medicine, which was founded by Lord Lister and a few colleagues, presented a letter recording the decision to signalize the anniversary by republishing all his works. Lord Lister expressed himself greatly pleased by the works. Lord Lister expressed himself headed a deputation from the Royal College of Surgeons by Professor Tilanus of Amsterdam presented an address from the physicians of that city. Another address was presented by Dr Madsen of Copenhagen bearing the signatures of 1000 Danish doctors. Lord Lister briefly replied to all the congratulations and presentations saying how greatly he felt honored by them. He enjoys excellent health, and may be seen daily talking walking exercise. He is a somewhat broadly set man in quasi clerical attire, with a strikingly leonine but kindly head.

The Manifesto on Alcohol.

As anticipated in a previous letter the manifesto signed by fifteen of the most eminent members of the profession advocating the use of alcohol has provoked a storm of contro-

PHARMACOLOGY

VOL. XLVIII
NUMBER 17

versy in both the medical and the lay press. A counter declaration has been issued by the British Medical Temperance Association for advancing the practice of total abstinence. The main propositions in the manifesto are criticised as follows: (1) Alcohol is sometimes valuable as a drug. This says the association, is much discussed in medical circles and is not to be settled by ipse dixit, however eminent. In large hospitals the amount used has diminished from 20 to 70 per cent during the last 20 years. (2) It is said that the universal belief that the moderate use of alcohol is beneficial for adults is amply justified. The belief is by no means universal, millions believe to the contrary. On the other hand, the experience of several life assurance companies and friendly societies shows that abstainers live longer, have less sickness and recover more quickly than non-abstainers. Abstainers can do more work and show greater endurance of cold, fatigue and hardship than non-abstainers. In 1903 an international medical manifesto was signed by many eminent English, American and European professors and by 664 physicians at the instance of the British Medical Temperance Association. This stated: (1) That experiments have demonstrated that small quantities of alcohol are injurious to disease and shortens life. (2) That it increases liability to disease and the liquor trade food, (3) that it increases liability to disease and shortens life. On the other hand, those engaged in favor of alcohol and life have eagerly seized on the manifesto in favor of alcohol and used it for all its worth. The Licensed Victuallers' Central Protective Association has reproduced it and distributed it broadcast in leaflets. On the other side the National Temperance League is about to hold a meeting to take decisive steps to counteract the effect of the manifesto on the masses. At the annual meeting of the Society for the Study of Inebriety, the President, Dr Harry Campbell, described the manifesto as misleading and harmful. Much of the whisky consumed he said, is raw, immature spirit, practically never more than two or three years old. Therefore, to say that the moderate use of alcohol is beneficial is to encourage the whisky drinking poor to poison themselves.

Pharmacology

The Viavi Treatment

Yet one more of what Samuel Hopkins Adams in "The Great American Fraud" calls the "fundamental fakes" has been exposed. The *California State Journal of Medicine* devotes six pages in its April issue to showing up "Viavi," and it is well done. It appears that two astute and, since they have made their millions, highly respected, men on the Pacific Coast conceived the idea some years ago of instituting a "treatment" for the ills peculiar to women. This "treatment" practically consisted—and, of course, as our contemporary scribbling vaginal douches. But, of course, as our contemporary says, "no large paying business could be built up by simply selling a little good advice and a trifle of common sense. There must be something definite to take, some wonderful secret and very costly remedy that will work the result, secure which the douche is but the merest preliminary. Hence the 'capsules' and the 'cerate' and the 'liquid' and the 'royal,' and the rest of the wonderful remedies which, collectively, leave little uncured or incurable by Viavi."

So Viavi is bought and the douche is taken. "The immediate increase of personal comfort and many times the quick relief from some annoying minor ailment, which follows this exercise of cleanliness and common sense might so hypnotize the average woman who accepts the Viavi preachments and takes the Viavi 'treatment' that she would be ready to believe almost anything the promoters care to tell her."

Inquiry was made as to whether the Viavi remedies contained morphia or any habit forming drug. Nothing of this sort was found in fact, as our contemporary says "It was unnecessary to put an expensive article like morphia and one liable to bring about trouble in the future, into their 'remedies' when they do not need to."

Then the question of conception. The query was answered by a most emphatic denial. The manufacturers were horrified at the thought of their remedy being put to such repulsive and frightful mis-use. The questioners wandered in the face of

such evident righteousness on the part of the makers of Viavi how they could have been led to think of such a thing. The thought may have been suggested by a paragraph in a book let put out by these people, called "Viavi Hygiene." Here we find that "the remarkable effectiveness of the Viavi pieces it in the power of health of their offspring for proper re-natural means." [The small capitals are inserted for emphasis by the California journal.]

An inability to correctly interpret what appears to be simple English is the only excuse that the enquirers have to offer for their unjust suspicions.

Naturally after two such rebuffs the question arose: What is Viavi? In the language of its makers—who ought to know—it "is purely a vegetable compound—more a food than a medicine, and is prepared in a predigested manner, so that it can be easily absorbed by the tissues of the body with which it comes in contact." But on the other hand analytical chemists reported: "So far as we are able to determine, they contain nothing but the extract of hydrastis and cocor butter."

But why quarrel about what this wonderful remedy is when we know what it will do? Gynecology, after the universal adoption of the Viavi treatment, will become a lost art and the gynecologist who is referred to in Viavi literature as a "body carpenter" will have to cease his sacrilegious "carpentry," for "a very large proportion of women's diseases were really incurable until the Viavi system of treatment was introduced."

But it is on the subject of etiology, pathology and treatment of tumors that Viavi literature really distinguishes itself. Could the cancer commission be but persuaded to read this enlightening treatise it would adjourn sine die. Like all great discoveries this one is remarkable for its simplicity. With the ingenuousness characteristic of great scientists the vexed problem of tumor causation is explained as follows: "The cause of these growths (tumors), which by inspiring terror drive so many women to a premature death by way of the operating table is so simple a thing as a poor circulation of the blood. Tumors are caused by a stagnation of the venous blood. This important discovery on our part has swept away the mist that has always surrounded this subject and enabled us to accomplish the most remarkable cures."

But not only will Viavi cause a diminution in the size of tissues not wanted but *mirabile dictu* it will bring about an increase in bulk in those tissues which are desired. For, say its exponents, we recall particularly the case of a man suffering from the Viavi cerate applied to the scrotum. The delightful ambiguity of this sentence by the way is an illustration of the shrewdness of their literature generally. It will be noticed that they do not say that the patient recovered from the condition for which he was treated but that he made a "perfect recovery from the Viavi cerate."

Where statements are made claiming more for the remedy than even the gullible lads would be willing to swallow the verbiage is so changed as to present the truth in the form of a tall tale. To six print blank that Viavi would cure appendicitis, paralysis, locomotor ataxia, et al would possibly arouse a healthy skepticism which would prove unhealthy for Viavi. We are told therefore in one part of the literature that all the diseases and many more proceed from a depletion of the blood—*from nervous debility* while elsewhere we are informed that Viavi cures nervous debility.

Such is our western contemporary's way of the business which has made two men starting with practically nothing affluent. Their patrons consist of confidence men and of women to whom not skilled in medicine their literature appeals.

We regret that we have not the space to quote the complete article. It is also to be regretted that a reprint of it cannot be placed in the hands of those who are interested in the effectiveness of this California "treatment."

Correspondence

Medical Practice Among the Maoris

AUCKLAND, NEW ZEALAND, Feb 25, 1907

To the Editor.—In the January 12 number of *THE JOURNAL* I find an extract from the *British Medical Journal* on "Phthisis and Superstition Among the Maoris." Perhaps your readers may be interested in some observations by myself while acting as local native health officer for four years among these interesting people.

All forms of tuberculosis are widespread among them, and even in localities where the conditions are naturally almost ideal for coping with this disease, it is increasing in all its forms. The principal reason for this is their national custom of holding a "tangi" over the dead. This consists of feasting and mourning of all the relatives of the deceased while the body lies in state, surrounded by weeping women and men who rub noses with one another, and cover and uncover the dead to show new arrivals. No matter what the nature of the disease, this custom is not interfered with. The police dare not interfere. I was once called on to perform an autopsy on a native who had died suddenly without any apparent reason, and when I arrived where the body was lying in state in a tent I was refused permission to do anything and it was only after the police had been called and the tent cleared that I could get to work. Half way through, the relatives returned with reinforcements to drive away the desecrating "pakeha tokuta" (whiteman doctor), and I had to be content with what I had done, especially as I had gone far enough to satisfy myself as to the cause of death. The result of this was that those natives had no use for me after ward. I was polluted and would pollute them if I touched them. It is not the policeman that the native child is threatened with as a last means of coercion, but the "pakeha tokuta."

Once I was called in to a native hut to see a sick child, whom I found to be suffering from a psoas abscess. This I opened, and for want of anything better at hand, gathered the pus in some absorbent cotton, and as the best means of getting rid of it, I put it in the cooking stove fire. They took that stove out and would never use it again and not even the fireplace. It was "tabu" ever afterward.

But the serious part of it is that their superstitions have such a hold on them that any wandering Maori "tohunga" (native doctor) who comes along with his incantations is allowed to take precedence and overrule the physician's authority and upset all his work. I once had as a patient a woman who was suffering from pneumonia. I rode many miles on horseback to see her, as I wished to reward the husband for his confidence in coming to me early and before he went to the Maori "tohunga" (doctor). I stayed two days with the woman, and left her on the road to recovery, and with every hope that she would recover. That night after I left she wanted to defecate, and could not be restrained from going to the customary place in the scrub a hundred feet or more from the house although it was raining hard. She got rapidly worse and died. They will not perform this act in a dwelling, for if they do the dwelling is unclean and can no longer be used as a dwelling.

Before the white man came it was the universal custom of the expectant mother to go off with the husband to a secluded place in the bush near a stream. After parturition which was always accomplished in the squatting position with the husband clasping his wife's abdomen from behind and aiding the expulsion by squeezing the woman would lie down in the running water and the husband knead her abdomen with his bare feet. The baby would be washed in the running stream, and all three would go back to the pa.

Never have I seen a Maori woman lie down as do white women after confinement. They can not be kept down. They sit up almost immediately and next day may be seen hanging out clothes on the line or doing something else just as unexpected.

In times past the Maoris, both male and female, bore pain

with the utmost stoicism. I have opened a painful felon for a Maori maiden, who did not flinch any more than if I had only cut her nails, and who looked on at it all the time. But these individuals are rare now. One Maori came to me with a beautifully ripe boil on his wrist and told me that he wanted me to put something on it that would cure it at once. His friend who came as interpreter said he would not have it cut, and knowing the native character well, I simply replied that I would give it only one touch with a remedy that would cure it at once. They were pleased, and I made elaborate preparations to conceal my real intention, and at the crucial moment made a slash with my secreted knife. He instantly fled howling like a madman, and I have not seen him since, but fortunately the other native was in sympathy with my action and I did not lose their confidence (as I properly deserved to), as the touch did all I said it would.

On another occasion I was called by an Irishman, who had married a full blooded Maori woman, to come and attend his wife in confinement. She had been in labor for three days when he returned from a journey to find her surrounded by all the old Maori women in the district who had given up hope. When I arrived on the scene they had all fled, for they recognized me from afar. The Irishman, who had never attended an event like this before, although he had had four teen children by this woman, was my only assistant. After really throwing the woman, for she resisted like a fiend, I applied the forceps. With the Irishman hanging on to her shoulders over the head of the bed, a baby was delivered of such dimensions that the father exclaimed when he saw it, "Doother, that's a man child sure!"

When a smallpox scare came on the country some four years ago, I was directed to vaccinate all the natives, both old and young, and strange to say, they took to this as ducks to water, and would arrive at my office or at the out stations in large parties of thirty to a hundred or more. By selecting the youngest baby first and performing the act painlessly on him, I could do the rest, both old and young, without hearing a whimper, and that without any effort to do it painlessly, but rather with every effort to do it expeditiously.

In the effort to get their names in order to record who had been vaccinated, I learned of a curious custom that prevails with them. One was named "Four o'clock." He was so named when a baby because one of the family had been drowned at 4 o'clock in the afternoon. Another was named "Glass," because at the time he was being fitted with a name a relative died and the coffin maker had sprung an innovation on the natives in the shape of a glass window in the coffin lid. Another child was named "Boots" because a member of the family had died with his boots on. I could recite numberless instances of this primitive way of originating new names.

The "tohunga" is the medicine man of the Maoris and in him they have unshakable faith. The "tohunga" makes most preposterous claims and has little difficulty in attracting a large following. I have known one to call himself Jesus Christ and to claim power to work miracles. He had a cure all which he compounded at the nearest saloon. It consisted of something out of every bottle or receptacle containing liquor—beer, gin, whiskey, brandy—some of each brand. Sick natives at a distance would send him \$200 and \$300 to come and lay his hands on them. This he would do with great solemnity and much quoting of scripture, and afterward spend the evening with his disciples in the nearest billiard room, interspersing his conversation with lurid oaths in the distraction of an exciting game.

One of these "tohungas" once tore off the bandages and dressings I had placed on a badly burned limb and plastered it with the filthiest mud in the neighborhood. In spite of this the burn healed and he was given credit for the cure.

Once a Maori gets it into his head that he is going to die no "tohunga" nor the cleverest physician could save him however easy the task. But once I knew of an old man whose relatives concluded he was about to die. They gathered all the tribe from far and near and much food and made every preparation for a glorious "tangi." He lay in his hut unconscious of all that was going on, but accidentally learned

they had really begun a "tangi" on his account. He said I will arise and help them, and he did. He had not made up his mind to die, and since all preparation had been made and everybody invited, it could not be put off. At these "tangis" sometimes six or seven hundred people will assemble and eat and drink almost continuously for days until the last scrap has been swallowed. At one a year or two ago twenty sheep, thirty pigs, two cows, a ton of potatoes, a ton of kumaras (sweet potatoes), half a ton of flour and many tons of fruit and jam and other eatables were consumed. All the food is prepared in the native fashion—in a hole lined with hot stones. Meanwhile, the dead lies stinking right in the middle of this feasting.

Like all superstitious peoples, they have a great horror of spirits, and I have yet to know the Maori who will venture alone in the dark.

Some time ago a steamer, which had been chartered and loaded with 400 Chinese dead men who had been accumulating in New Zealand for some time, foundered off the coast near where I was stationed. Some of the boxes came ashore. One was found by a European and Maori who were riding in company along the beach. They naturally supposed they had found something valuable and opened the outer and then the inner casing, when they came on the lead lining. The European then suspected what they had hold of and allowed the Maori to open the lead lining. He did so, and as soon as he saw the shriveled up, parchment like features of the dead Chinaman, he sprang aside, ran for his horse, mounted and galloped away. The beach is 70 miles long, and the European could see him riding for fully an hour as hard as he could make his horse go, and then he went out of sight. And yet the Maoris are brave and resourceful in danger. I have known them to exhibit courage equal in every degree to the best. They have great love for their children, but care little for their old people.

In conclusion, I will relate the experience I had with one of these medicolegal clerico-schoolmasters (I mean no reflection on them as a class). About 70 miles from my station was a native school with about 90 children in attendance. Whooping cough was prevalent. This man did what he could, but was foolish enough to think he knew everything and refused the assistance I was authorized to proffer him. Everything went well until one day he bethought him to take the temperature of his charges. He only had an ordinary wall thermometer in a metal case. Thus he placed in the mouth of every youngster. It was quite a mouthful. He got an average temperature of 96 degrees. He became alarmed and rode some miles to wire to Wellington, the capital of the country, that a large number of children were in a very serious condition and to plead for help. I received an urgent message to travel fast to their aid. All the patients came out to greet me mostly clad in shirts and some were very short shirts. But for some severe coughing nothing seemed wrong, and perplexed and I turned to the schoolmaster for an explanation. Well, it transpired that he had heard that no one could live long with a rise of temperature more than 7 or 8 degrees above normal, and he understood the normal temperature was 60 F. This man was called by the natives a "pakeha Maori," which has much the same meaning as does "white trash" in some parts of the United States.

Dr Pomare, the chief native health officer himself a half caste and educated in Chicago states that in thirty years there will not be a full blooded Maori in existence. While they are building houses like those of the white man, they fail to ventilate or properly drain around them. They often live day and night in the same clothes, frequently allowing wet clothes to dry on their bodies. They alternately feast and starve. After a "tangi" they will have little to eat sometimes for weeks together.

The half castes are mostly debilitate and tuberculosis is very prevalent among them. The pulmonary form is the most common. As they do not come under skilled care until well advanced nothing can be done to check it and they have lost faith in the ability of the "pakeha tokuta" to do them any good.

JOHN S. REEVE, M.D. CH.M.

A New Trypanosome.

OTTAWA, ONT. April 19 1907

To the Editor.—Pathologists will be interested in the information that the *Trypanosoma equiperdum* has been found in a mare clinically affected with dourine, or *maladie du coit* at the quarantine station established by this department at Lethbridge, Alberta, in 1904. The first demonstration was made by Drs. E. A. Watson and M. V. Gallivan on Feb. 11 1907, in material taken from a vesicle on the mucous membrane of the vagina of the animal above referred to which was found to be affected with dourine on the premises of her owner, Mr. R. Tiffin, near Lethbridge on Dec. 21, 1906, and subsequently removed to the quarantine station for purposes of experimental observation.

The disease was successfully transmitted in February to a yearling filly and the parasite subsequently observed in preparations from a fresh plaque. The finding was confirmed by Dr. C. H. Higgins, pathologist of the department, on March 21, and was further observed in preparations taken by him on March 23 and 25.

The identity of dourine, or *maladie du coit*, as seen on this continent and hitherto diagnosed by American and Canadian veterinarians from clinical manifestations alone, with the disease as known in Africa and Asia, as well as in southern Europe, is thus fully established.

A detailed report of the discovery and of the work which led up to it, as well as of the steps subsequently taken, will be issued at the earliest possible date.

J. G. RUTHERFORD

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGAN-
IZATION CONTRACT PRACTICE INSURANCE FEES
MEDICAL LEGISLATION, ETC

Workmen's Insurance in Germany

During a recent visit to this country Prof. Frederick Müller read a paper at the Boston Medical Library on "Social Legislation in Germany and Its Influence on the Care of the Sick." It is significant that Professor Müller considered social medicine of sufficient importance as a subject for one of the few papers which he read in this country, instead of taking up some phase of technical work.

Professor Müller emphasized the fact that in Germany the relation between the medical profession and the state has assumed much greater importance than it has, as yet, in America. National legislation along this line was begun in Germany in 1883, by providing for compulsory industrial insurance against disease, invalidism and old age, and accident. At present 15,000,000 people in the German Empire are protected by the first form of insurance. Each individual who works for wages pays two thirds of the cost of his insurance, the other third being paid by the employer. For this the employé receives free medical treatment and medicine, either at home or in a public hospital, for six months, if necessary. He also receives half pay for the time for which he is incapacitated, and, if he dies within six months, a certain amount is paid to his family. This form of insurance protects against acute diseases.

A second form, which provides for chronic invalidism and old age, insures a certain amount to each working person of 70, as well as to persons under 70 who may be physically disabled. Chronic and incurable diseases entitle the insured to a benefit, if he is incapable of earning one-third of the wages which he earned before contracting the disease. This form of insurance is held by about 12,000,000 people, and the amount of benefit paid runs from \$45 to \$120 per year, one-half of which is paid by the employers and one-half by the employé's.

The third form of insurance is against accident. The entire amount of the benefit in this case is paid by the employer. The natural result is to stimulate every possible care regarding accidents and the use of all forms of safety devices on machinery. A certain sum is paid for crippling and disabling injuries. Professor Müller stated that while this plan naturally results in a considerable amount of malingering on the part of the employé's, it is felt that the beneficial results outweigh the harmful. In spite of the great increase in German industries the number of accidents have actually, as well as relatively decreased in the last years.

An interesting feature of this plan of workmen's insur-

ance is its bearing on the medical profession. The first arrangements provided that each insurance company organized under the protection and encouragement of the state should have a surgeon who should do all the work for that company. This led to great reduction in fees, and finally to the "doctors' strike," concerning which so much has been said. The result of the refusal of the physicians to work for the amount named was that the fees were raised and the patient was also given the right to choose his own physician.

The experience of the profession and the public regarding workmen's insurance in Germany is of interest to physicians in this country. The workings of the German system should be carefully watched in order that if such a plan is ever inaugurated here we may profit by the lessons which have been learned in that country.

One Physician's Influence

A striking illustration of the influence which physicians can have in public affairs is furnished by Dr. George T. McWhorter of Riverton, Ala., who for the last year has been president of the Medical Association of the State of Alabama, and who is also a state senator. As president of the admirable organization of physicians in Alabama, Dr. McWhorter is in a position to speak authoritatively in the state senate for his profession. Among other bills which he has recently introduced is one providing for an epileptic colony for the care and treatment of epileptic patients, either at the public charge or at the cost of their friends. The bill has the endorsement of the state association and will probably be passed.

Writing regarding the work of the legislature in his state, Dr. McWhorter stated in a recent letter: "Medical men have been sadly derelict in bringing to bear the influence on public affairs which should have been exerted by a learned and influential profession. We have tamely relinquished almost all political power and influence until, as a profession, we have almost ceased to be a factor in shaping legislation. We are largely to blame for this ourselves, as we have maintained an attitude of cold hostility toward any member of our profession who ventured to seek political preferment, no matter how able and well qualified he might be. In the meantime we have begged favors when we should have been in position to have dispensed them."

"We should not submit to being relegated to a subordinate position. We should take a lesson from the legal profession on this subject. We should steadily and persistently demand the establishment of a department of public health in the United States, with a representative of the first rank of our profession in the cabinet of the President. The necessities of the age demand this and it is due the medical profession. Many of the most important problems of to-day are sanitary and hygienic in character. All thoughtful men now recognize the fact that the sanitary problems at Panama dominate and control the engineering difficulties, vast and complicated as the latter are. The men who plan and institute sanitary measures of such transcendent importance to the success of military undertakings, as well as commercial and industrial enterprises, should receive proper recognition from the government they serve."

"The domain of the legislator has been immensely widened. The lawmaker now needs the assistance, counsel and advice which can only be had from the thoroughly trained medical man. The legislation of the age should reflect the science of the age and conform to its medical needs. It can not do so unless guided by men familiar with medical science and acquainted with its needs. A department of public health in charge of a high grade physician, his annual reports to the President, to be in turn, transmitted to Congress, would set before our national legislators the demands of commerce as well as the medical needs of the people."

Dr. E. E. Maxey, secretary of the Idaho State Medical Society reports the passage of a bill providing for a state board of health and making an appropriation for its support for two years. Two bills introduced into the legislature which provided for serious modifications of the present medical practice act were killed in committee.

Austin S Tinsley, M.D. University of Georgia, Medical Department, Augusta, 1888, a member of the Georgia State and Richmond County medical societies, died at his home in Augusta, April 16, after an illness of two weeks, aged 38

William W Genge, M.D. Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons, Kingston, Ont., 1891, died at his home in St Johnsbury, Vt., April 10, from pneumonia, after a short illness, aged 39

Dietrich C Husmann, M.D. Western Reserve University Medical College, Cleveland, Ohio, 1879, at one time a member of the board of education, died at his home in Cleveland, April 12, from acute disease of the liver, aged 59

Raymond Palmer Robbins, M.D. Minnesota Hospital Medical College, College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1904, died at his home in Portland, Ore., April 16, from spinal meningitis, aged 27

William Armes, M.D. (Licensed Kentucky, 1867), a member of the Grayson County (Ky.) Medical Society, died at his home in Shrewsbury, Ky., March 6, from pneumonia, after an illness of six days, aged 77

F P Brunthaven, M.D. Medical Department of Western Reserve University, Cleveland, Ohio, 1889, of Tomales, Cal., died from appendicitis at the French Hospital, San Francisco, April 4

Oliver Crook Haugh, M.D. Louisville (Ky.) Medical College, 1893, convicted of the murder of his father, mother and brother in 1905, was electrocuted at Columbus, Ohio, April 20

Jason L Edgar, M.D. University of Missouri Medical Department, Columbia, 1875, died suddenly at his home in Clearwater, Fla., March 13, from cerebral hemorrhage, aged 63

Thomas S Parr, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1886, died at his home in Indianola, Iowa, January 2, from appendicitis, aged 64

Henry Swayer Hahn, M.D. Indiana Medical College, La Porte, 1848, city physician of Chicago in 1870, died at the residence of his daughter in that city, April 17, aged 81

Jerome B Lawrence, M.D. New York Homeopathic Medical College and Hospital New York City, 1885, died at his home in Brooklyn, N. Y., April 11, after a long illness

William S Patterson, M.D. Medical College of Ohio, Medical Department of University of Cincinnati, 1853, died at his home in Hillsboro, Ohio, Dec. 30, 1906, aged 76

G Hamlin Anderson, M.D. Hahnemann Medical College and Hospital of Chicago, 1886, died at his home in Seneca, Kan., April 9, after an illness of four years, aged 46

Edward P Miller, M.D. Hahnemann Medical College and Hospital Chicago 1871 for many years a practitioner of Chicago, died in Denver, Colo., April 15, aged 65

G W Mason, M.D. Chicago Medical College, 1880, for many years a prominent physician of Monroe County, Ohio, died at his home in Stafford, April 8, aged 80

Emory W Blackburn, M.D. Eclectic Medical Institute, Cincinnati, 1885, died at his home in Latrobe, Pa., April 4, from septicemia, due to a carbuncle

John L Brown, M.D. University of Nebraska College of Medicine, Lincoln and Omaha, 1904, died at his home in Western Neb., February 4

A Theodore Braxton, M.D. Meharry Medical College, Nashville, Tenn. 1897, died at his home in Columbia, Tenn., April 8, from tuberculosis

Helene C Byington, M.D. Boston University School of Medicine, 1896, died at her home in Montrose, Colo., April 13, from influenza, aged 47

William F Noe, M.D. Barnes Medical College, St. Louis 1901, was shot and killed in his office in Mountain Home, Ark., February 8, aged 38

Charles Eugene Casgrain, M.D. McGill University Medical Faculty Montreal, 1851, died at his home in Windsor, Ont., March 8, aged 82

J A Meek, M.D. Southern Botanical Medical College, Macon Ga. 1871, died at his home in Jonesboro, Ark., recently, aged 76

Death Abroad.

Thomas Henry Wakley, F.R.C.S., senior editor and proprietor of the *Lancet* died at his residence in Queen's Gate, London on April 5, aged 86. He was the eldest son of Thomas Wakley the founder of the *Lancet* and well known coroner and member of Parliament, who was associated with all the advanced political movements of the early Victorian days. He was educated at University College, London, became a member of the

College of Surgeons in 1845, and a fellow four years later. In 1848 he was appointed surgeon to the Royal Free Hospital, where he established a reputation as a skilful operator. He devoted himself specially to aural surgery and orthopedics and attained an extensive practice. On the death of his father, in 1862, he became manager of the *Lancet*, his younger brother, Dr James Wakley, being the editor. His new duties led to the gradual abandonment of practice, and in 1886, on the premature death of his brother, he took over the editorship of the paper in conjunction with his son. Under this joint editorship the journal has progressed on the lines laid down by its founder, and has maintained the highest position from all standpoints—scientific, literary and ethical. Like most successful editors, Mr Wakley did not write much, but he was skilful and keen in discovering men who could write and what they could write. Like his father, he was bold in exposing public evils. His principal original work was an article on "Diseases of Joints," contributed to Samuel Cooper's "Surgical Dictionary," then the standard work on surgery in England. His sympathy with the profession was shown by many private acts of generosity as well as by the foundation of the *Lancet* relief fund, contributed entirely by himself and his son to meet unforeseen and urgent pecuniary exigencies among members of the profession. His activity, physical and mental was unbounded. He was never ill and never absent from his duties. Even in his eighty second year he journeyed to the office daily from Brighton (where he spent the summer). He leaves a widow, a son, Thomas Wakley, Jr., who has been for twenty years his father's colleague in the editorship of the *Lancet*, and a daughter.

The Public Service

Army Changes

Memorandum of changes of stations and duties of medical officers U. S. Army for the week ending April 20, 1907

Snyder Henry D. surgeon granted thirty days leave of absence, with permission to apply for fifteen days extension

Usher F. M. C. asst. surgeon relieved from duty at Fort Brady, Mich. and will proceed to San Francisco and report not later than April 29, 1907, to the medical superintendent Army Transport Service that city for duty as surgeon transport *Buford* during the voyage of that vessel to China and the Philippine Islands. On arrival at Manila Captain Usher will report in person to the commanding general Philippines Division for assignment to duty

Bloombergh Horace D. asst. surgeon detailed as a member of the examining board appointed to meet at Fort Riley, Kans., vice Captain Elmer A. Dean asst. surgeon hereby relieved.

Wiltmore Eugene R. asst. surgeon relieved from duty at Fort Jay, N. Y. and ordered to Fort Riley, Kans. for duty

Dean Elmer A. asst. surgeon granted ten days leave of absence

Bosley John R. asst. surgeon left Jefferson Barracks, Mo. on ten days leave of absence

Adair George W. asst. surgeon general granted fifteen days leave of absence

Wadhams S. H. asst. surgeon granted leave of absence for one month on surgeon's certificate of disability

Girard Joseph B. asst. surgeon general on the expiration of his present leave of absence, will proceed to Atlanta, Ga. and report in person to the commanding general Department of the Gulf for duty as chief surgeon of that department, relieving Lieutenant Colonel William W. Gray deputy surgeon general

Gray William W. deputy surgeon general on being relieved from duty as chief surgeon Department of the Gulf by Colonel Joseph B. Girard asst. surgeon general will proceed to Omaha and report in person to the commanding general Department of the Missouri for duty as chief surgeon of that department relieving Lieutenant Colonel John M. Banister deputy surgeon general

Banister John M. deputy surgeon general on being relieved from temporary duty as chief surgeon Department of the Missouri by Lieutenant Colonel William W. Gray deputy surgeon general will return to his proper station Fort Riley, Kans.

Flagg Charles F. B. asst. surgeon granted leave of absence for four months to take effect on or about May 1 with permission to apply for an extension of one month

Bell Richard P. contract surgeon ordered from Fort Wadsworth, N. Y. to temporary duty as surgeon of the transport *Killpatrick*

Johnstone Ernest K. contract surgeon ordered to accompany troops to duty in Yosemite National Park

Bell Leonard P. contract surgeon relieved from duty in the Philippines Division and ordered to Fort Riley, Kans. for duty

Newton Ralph W. contract surgeon relieved from duty at Fort Niagara, N. Y. and ordered home Barre, Vt. for annulment of contract

Wren Rinaldo J. contract surgeon ordered to Fort Totten, N. Y. for duty

Robert Michael A. contract surgeon relieved from duty at Fort Totten, N. Y. and ordered to Fort Terry, N. Y. for duty

Suggs Frank. contract surgeon relieved from duty at Fort Terry, N. Y. and ordered to Fort Niagara, N. Y. for duty

Card Daniel P. contract surgeon ordered to Fort Jay, N. Y. for duty

Trotter George T. contract surgeon left Fort Monroe, Va. for duty at West Point, N. Y.

Stephenson Andrew V. contract surgeon ordered from Fort Omaha, Neb. to San Francisco for duty in the Department of

California

Stallman George D dental surgeon left Fort McIntosh Texas for duty at Fort Reno Okla
 Voorhes Hugh G dental surgeon arrived at San Francisco Cal on the transport Logan for treatment at the General Hospital San Francisco
 Patterson Edwin W contract surgeon arrived at San Francisco on the transport Logan on leave of absence for three months

Navy Changes

Changes in the Medical Corps U S Navy for the week ending April 20 1907

Gatewood J D surgeon ordered to additional duty in the Bureau of Medicine and Surgery Navy Department.

Bertolette D N, medical director sick leave further extended three months

Delancy C H P A surgeon ordered to Naval Medical School Hospital Washington D C for treatment and observation.

Downey J C assistant surgeon granted leave for one year from April 15

McGulgan J H, pharmacist, granted sick leave for three months

Spear R surgeon when discharged from treatment at the Naval Hospital Mare Island Cal ordered home and granted sick leave for two months

Public Health and Marine Hospital Service.

List of changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine Hospital Service for the seven days ended April 17 1907

Carrington P M surgeon granted leave of absence for 3 days from April 15 1907 under Paragraph 189 of the Regulations

Fox Carroll P A surgeon granted an extension of leave of absence for 15 days from April 20 1907

Berry T D P A surgeon granted leave of absence for 1 day

Stimson, A M, asst. surgeon, leave of absence granted for 7 days from April 6 1907 under Paragraph 181 of the Regulations amended to read for 5 days

Rucker W C asst. surgeon directed to proceed to Norfolk Va and assume charge of the Service exhibit at the Jamestown Ter Centennial Exposition at Hampton Roads Va

Ward W K, asst. surgeon granted leave of absence for 1 month or so much thereof as may be necessary on account of sickness from April 7 1907

Salmon T V, asst. surgeon granted leave of absence for 10 days from April 19 1907

Walker T Dyson acting asst surgeon granted leave of absence for 9 days from April 12 1907

Holt T M pharmacist authorized to proceed to New Orleans special temporary duty once each month for 3 months on completion of which to rejoin station

BOARDS CONVENED

A board of medical officers was convened to meet at Wilmington N C April 16 1907 for the physical examination of an officer of the Revenue-Cutter Service Detail for the board P A Surgeon C H Lavinder chairman

A board of medical officers was convened to meet at Seattle Wash April 19 1907 for the purpose of examining an alien immigrant. Detail for the board P A Surgeon J H Oakley chairman Asst Surgeon H G Ebert Acting Asst Surgeon I R Underwood Recorder

MEDICAL ASSOCIATION OF GEORGIA

Fifty Eighth Annual Session held at Savannah April 17 19, 1907

The President Dr H H MARTIN Savannah in the Chair

After the customary address of welcome the reading of papers began the scientific work being divided into two sections medical and surgical

The Training of Epileptic and Feeble Minded Children

DR. WISLEY TAYLOR, Atlanta, advocated a state school for the feeble minded and epileptic open and free to any one in the state either to train their children up to a certain standard of efficiency or to relieve them of their embarrassing condition. He

asked the cooperation and endorsement of the association. Manual training is at length beginning to be appreciated and valued as it deserves, and in connection with other training it is intended to teach some useful and simple trade to those incapacitated for such work.

DR. H. D. ALLEN, Milledgeville, thinks it is incumbent on the state to establish a colony for the epileptic and feeble minded. It is known how much good has been done for the deaf and dumb. The deaf and dumb can be taught to read and write by experienced teachers. Feeble minded children can not be properly cared for at home, for the reason that members of the family are too indulgent or too harsh. They do not regard the children as defective, they think many of the things they do are done through pure meanness or are prompted by an evil spirit.

DR. R. R. KIME, Atlanta, said it is time the Medical Association of Georgia and the state at large should awaken to its duty along humanitarian lines. The epileptic or feeble minded children are not responsible for their condition, they are brought into the world with defects they can not themselves eliminate, and physicians as representatives of one of the great professions of the state have a duty and responsibility resting on them which they can not shift without doing themselves an injustice. There is no class of defectives that need the sympathy and support of the medical profession, as well as the people of the state, more than the epileptic and feeble minded.

Dr. Kime offered a resolution to the effect that the association endorse the idea of requesting the establishment of a state colony for epileptics and an industrial school for feeble minded. This resolution was unanimously carried.

The Soda Fountain and Its Attendant Evils

DR. J. A. COMBS, Locust Grove, read a paper on this subject. He finds that the soda fountain has nothing for which to commend itself either to the medical profession or to the public, but he thinks the following serious objections may be justly urged against it. It fosters the nostrum evil, it is a fruitful source of nervous and digestive disturbances, by its filthiness it may be and probably is the means of spreading infectious diseases. It offers opportunity for the illicit sale of whiskeys and other narcotics. The powerful drugs dispensed in the "patent" or secret drinks create a thirst which leads to crime and disgrace. It affords opportunity or undesirable commingling of the sexes. It paves the way for the wine and beer garden, and at last for the saloon.

The Doctor in Relation to Exercise as a Factor in Medicine and Surgery

DR. THEODORE TOEFEL, Atlanta, said the orthopedic surgeon needs exercise and massage in his corrective work. Lateral curvature of the spine is no longer treated by braces exclusively, but by gymnastics, sometimes in connection with other measures. It is true, but always by exercise in some form. The author explained the physiology of exercise and its therapeutic applications. He divided the system of exercise into passive, active and resistive, each division being discussed at length.

(To be continued)

TENNESSEE STATE MEDICAL ASSOCIATION

Ninety-fourth Annual Session, held at Nashville, April 9-11 1907

(Concluded from page 1372)

Tuberculosis of Kidney

DR. RICHARD DOUGLAS, Nashville, impressed on the general practitioner the importance of collective evidence and of a correct history in diagnosis. The patient, in 75 per cent. of the cases, is a woman between the ages of 20 and 40. Careful investigation will reveal the history of some rather protracted and unexplained illness, a decline in health for some months

Not infrequently the onset is more acute, and the febrile state is mistaken for some of the essential fevers, as in two of his patients. He called attention to polyuria, occurring particularly at night. The voiding of large quantities of clear urine is quite suggestive, indicating the stage of irritation which is followed later by congestion. If the urine is examined, microscopic quantities of blood will be found, but the characteristic of the hematuria in renal tuberculosis is a spontaneous occurrence of a quantity of free blood sufficient to be detected with the unaided eye. This bleeding is not induced by exercise or exertion, it merely marks the early stage of invasion of the kidney. Ureteral catheterization is not an essential, though a great aid to specific diagnosis. In 80 per cent of the cases only one kidney is affected. Radical removal of the diseased kidney and ureter by lumbar nephrectomy should be undertaken at once, the condition of the patient permitting it. Nephrotomy or partial nephrectomy is dangerous.

Tuberculosis in the Negro

DR. E. H. JONES, Murfreesboro, said that one feature with reference to tuberculosis in the negro race is that a large proportion of the cases are of the acute phthisic variety, running a rapid and fatal course, yielding little to the measures usually instituted. Those who are familiar with the habits of this race know their morbid proclivities for crowding around their sick and attending the funerals in crowded houses, ill ventilated, and not in the best of sanitary conditions. He believes that every house, tent or apartment used for dwelling purposes, when vacated, should be thoroughly disinfected before being occupied again. From observation, this is one of the most dangerous sources of contamination. This applies to public carriers, hotels, passenger trains, day coaches, sleepers, passenger boats and steamers, railroad stations, etc.

Lesions of the Prostatic Urethra and Their Reflex Neuroses.

DR. JERE L. CROOK, Jackson, said his attention was first directed to the prostatic urethra as a causal factor in neurasthenia and other neuroses about four years ago, when treating a college student for nightly seminal emissions. The history of the case was negative as to any form of venereal disease. The patient had practiced masturbation more or less. By means of a direct light urethroscope he found it easy to examine the entire urethra. Examination made after cocaineizing the urethra and performing meatotomy disclosed a hyperemic area about one inch long in the prostatic urethra. This was extremely sensitive. The diseased patch included the point of entrance of the seminal duct. By the use of nitrate of silver solutions of varying strength he was enabled to cure the local conditions and when this was done the other symptoms vanished. No other treatment was required. Since then he has successfully treated a number of cases according to this plan.

Surgery of Prostate

DR. W. A. BRYAN, Nashville, said the method of removal of the prostate depends on the operator. The results of the supra pubic and the perineal routes are slightly in favor of the latter. The mortality of either is small compared with non-operative treatment. Fistulas are seen occasionally, but they do not usually persist long, and when they do, can usually be relieved by curetting away their lining. If they do persist, it is better to have a vent through two openings than one. Not every patient can stand a prostatectomy, then permanent drainage may be instituted, or, if preferable, a two-time operation may be executed after the suggestion of Chetwood. When the patient is very feeble he will improve by simply draining the bladder either suprapubically or perineally. This may be done, and after a sufficient lapse of time, if the symptoms subside sufficiently, a complete removal of the gland may be done with a much lower mortality than would have been possible. Every step should be taken during the interim to assuage the infection of the bladder and kidneys and to build up the patient's resistance for the more serious undertaking. In all very old men it is preferable to do some minor operation, prolong life and relieve pain even if only with halfway comfort than to attempt the ideal treatment and fail. He condemned the partial excision of a large prostate in those patients whose condition warrants radical measures.

Suprapubic Prostatectomy

DR COOPER HOLTZCLAW, Chattanooga, described the technique and advantages of the suprapubic operation, and among other things said it requires no skilled assistants and no special instruments to do this operation. The only grave danger is entering the abdominal cavity. The whole operation need not take but a few minutes. If, however, the patient is old and feeble and exhausted by long and continued suffering and infection, the operation can be done in two stages. He most earnestly recommended this plan, as he had pursued it several times, opening the bladder under cocaine anesthesia, letting the patient recuperate from all his troubles, and then in a week or two removing the prostate under general anesthesia. He uses no drainage tube. He seldom finds it necessary to irrigate the bladder. He lets the bladder wound heal slowly by granulation, which is usually accomplished in from four to six weeks, by which time the wounds in the bottom of the bladder will have healed and contracted, thereby making a complete and effectual exit to the urethra. He allows the patient to sit up in three or four days, when he can be taught to take care of himself. The lack of experience, the rapidity and facility of the operation, the freedom from hemorrhage and unpleasant sequelæ, the more perfect drainage and satisfactory results, all appeal to him in recommending this method of operating.

Researches in Rabies.

DR. WILLIAM LITTERER, Nashville, discussed the significance of the Negri bodies, the diagnosis of rabies, and then referred to his original experimental work. He said (1) It is the consensus of opinion that the Negri bodies are the true etiologic factors in rabies. (2) They are living organisms belonging to the class of protozoa. (3) When found in smears or sections of the central nervous system, they are specific for this disease. (4) These bodies have never been found in other diseases than hydrophobia.

Recurrent Non Malarial Hematuria

DR. T. J. HAPPEL, Trenton, emphasized the necessity of careful diagnosis in differentiating the forms of recurrent non malarial hematuria. He said that the use of the microscope is most essential, because a careful examination will, in some cases, reveal the presence of some parasite other than the malarial hematozoön. The fact that some of these cases are cured by methylene blue may be taken as strong presumptive evidence that the condition is caused by the schistosoma hematobium.

Cancer of the Breast.

DR. W. D. HAGGARD, Nashville, pointed out the factors which influence the permanence of cure in operations for carcinoma of the breast. It may be stated as an axiom that cancer is an entirely curable disease when situated in an organ or tissue which of itself is completely removed without causing death, and if there is lymphatic involvement of the immediate tributary lymph glands, that they also are thoroughly removable. The younger the patient the worse the prognosis. In elderly persons, where there is a general atrophy of the lymph system and changes in all the vessels, dissemination is more slow. Cancer will remain local a longer period of time in the older patient, and the prognosis is better. The contraindications to operation were enumerated and the details of the operation described.

Other Papers Read

The following papers were also read:

Non Infectious Sclerotic Ovary by John A. Gaines, Nashville.
The Practical Use of Opium in Treatment in Certain Specific Infections Especially Those of the Skin by Dr. J. M. King, Nashville.
Treatment of Fractures of the Hip by Dr. C. N. Gordon, Nashville.
Surgery of the Thyroid Gland by Dr. Charles H. Mayo, Rochester, Minn.
Foreign Bodies in the Larynx and Trachea by Dr. M. M. Cullom, Nashville.
Headaches by Dr. Hazel Padgett, Nashville.
Inversion of the Uterus: Reports of Two Cases by Dr. B. V. Dickson, Cornington.
True Croup (Non Diphtheritic) by Dr. Walter Dotson, Kempville.
Appendicitis by Dr. R. J. McCall, Cumberland City.
Local Anesthesia by Dr. Paul DeWitt, Nashville.
The Etiology Pathology and Prophylaxis of Puerperal Prolapsus by Dr. C. W. Moore, Shelbyville.
Report of an Unusual Case of Ununited Fracture of the Humerus by Dr. Duncan Freese, Nashville.
The Differential Diagnosis of Multiple Sclerosis and Muscular Atrophy by Dr. D. R. Nell, Nashville.
An Ovarian Cyst Cast of the Abdominal Cavity by Dr. Wm. D. Sumpter, Nashville.
Carcinoma by Dr. J. T. Herron, Jackson.
Cerebrospinal Meningitis by Dr. William McCague, Nashville.

Book Notices

DISEASES OF THE LUNGS Designed to be a Practical Presentation of the Subject for the Use of Students and Practitioners of Medicine. By Robert H. Babcock, A. M., M. D., Consulting Physician to Cook County Hospital. Twelve Colored Plates and 104 Text Illustrations. First Edition. Cloth. Pp. 809. Price \$6.00. New York: D. Appleton & Co. 1907.

This is designed to supplement Dr. Babcock's book on "Diseases of the Circulatory System" and covers the subject of the diseases of the lungs rather thoroughly with the exception of the diseases of the pleura to which are devoted but seventy of the 770 pages which comprise the text. The chapters on bronchitis are fairly complete, though necessarily abbreviated, particularly the one on bronchial asthma. In his preparation of the text of these chapters the author has relied largely on the writings of Hoffmann and of Lenhartz. In general, however, and be it added much to his credit, he has been not so much a searcher of medical literature as a student of individual patients.

The chapters on Acute Fibrinous Pneumonia are far better than the single chapter devoted to Acute Bronchopneumonia. Pulmonary emphysema seems to the reviewer rather slighted inasmuch as it is of much clinical interest by reason of its frequent occurrence. For example, its relative importance demands a greater amount of space than is given to atelectasis and pneumoconiosis. The best portion of the book by far is that which is devoted to pulmonary tuberculosis, and we are especially pleased to see the author's advocacy of infection as opposed to the old idea of hereditary predisposition. The chapter devoted to the physical signs and clinical varieties of pulmonary tuberculosis is the best chapter on physical diagnosis in the book. That devoted to the treatment of pulmonary tuberculosis embraces all of the modern methods in regard to the best way of managing this dread disease. The author is not so fortunate in his description of acute miliary tuberculosis, which includes less than three pages. This is by no means an uncommon infection and is less frequently diagnosed than it should be. Surely, in comprehensive works like this one of Dr. Babcock's more than fourteen lines should be given to the physical signs of acute miliary tuberculosis; yet that amount is all that appears in the text. Indeed, in general, one could wish that less space had been surrendered to symptomatology, so that more might have been left for physical signs.

Mechanically, the volume is well gotten up. The fact that the author mentions the names of physicians who have from time to time called him as a consultant seems open to criticism. What benefit the names and home addresses of such physicians can be to the general reader is hard to estimate. In the interest of brevity, if for no other reason these names should be omitted. The style of the book is excellent. Indeed at times the author's elegance and fluency get the better of strength and force. Things which should stand out ruggedly are by the ease and flow of language so smoothed down that their relative importance is lost sight of. There is not a single epigram in the book for this same reason.

TUMORS INNOCENT AND MALIGNANT Their Clinical Character and Appropriate Treatment. By J. Bland Sutton, M. D., Surgeon to and Member of the Cancer Investigation Committee of the Middlesex Hospital. Fourth Edition with 377 Engravings. Cloth. Pp. 675. Price \$4.00 net. Chicago: W. T. Keener & Co. 1907.

This book, now in its fourth edition is of value chiefly because of the interesting manner in which a varied clinical experience with tumors has been utilized in the presentation of the subjects discussed. In no sense however is the work complete and it is far from being up to date. Hisologic considerations are scanty and uninteresting and the majority of the illustrations of microscopic sections are pathetically poor. The important features of tumor biology are entirely neglected or discussed in a most superficial manner and the author disregards almost entirely the essential features of histogenesis. A few references are attached to each chapter but they are of little value consisting of a most haphazard collection of articles largely reports of cases and a miscellaneous literature while important contributions to the subject are written in other books.

From the standpoint of the pathologist this book contains little that would cause him to recommend it either to elementary students or to men engaged in research. It does contain considerable information that will be found useful to the practitioner and surgeon, but the lack of completeness and its general superficiality will be at once evident to the man of much training and experience. A feature of value to the general practitioner is the method of considering the various sorts of tumors, particularly with reference to the different organs and tissues they attack, which enables one to readily acquaint himself with the relative prevalence of different sorts of tumors in each part of the body. Teratoid growths have received particular attention, as also have odontomas.

The defects are largely those of omission rather than of commission, for there are few erroneous statements, however, many good authorities would challenge the dictum that an adenoma never becomes transformed into a cancer (p. 267). One also occasionally notes with pleasure certain advanced ideas, e. g., the statement that "it would be convenient and perfectly justifiable to deprive myxomata of even the rank of species among tumors" (p. 60). The favorable results from local removal of giant cell sarcoma of bone and the usual absence of true malignancy in this form of tumor, is also well brought out, although no reference is made to certain important contributions to this subject.

PROGRESSIVE MEDICINE Vol. 1 March 1907. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in Jefferson Medical College. Paper. Pp. 280. Illustrated. Per annum in four cloth bound volumes \$9.00 in paper binding \$6.00. Philadelphia: Lea Bros. & Co.

In this issue Dr. C. H. Frazier, in the Department of Surgery of the Head, Neck and Thorax, presents a complete review of the practical bearing of edema of the brain in early operations for intracranial injuries, and gives a résumé of 530 cases of fractures of the base of the skull. Among other topics discussed are the following: Results of thyroidectomy in over a thousand cases, a summary of 16 cases of suture of the heart, operations on the pituitary body, trifacial neuralgia, epilepsy and cerebral abscess. Dr. Robert H. Preble devotes considerable space to the part taken by insects in the transmission of various infectious diseases. Dr. Floyd M. Crandall discusses the incidence of disease in childhood, infantile mortality, the tonsil as a portal of microbic infection, hernia in young children, enuresis, infant feeding, the management of infants in hot weather, etc. The Department of Rhinology and Laryngology is covered thoroughly by Dr. D. Braden Kyle, and the Department of Otology by Dr. B. A. Randall. The latter reviews 645 cases of brain abscess. Dr. Kyle discusses the use of chlorid of sodium in the treatment of chronic laryngitis and reports a case of inoperable cancer treated with a bacterial vaccine made from a micrococcus neoformans.

PEDIATRICS: The Hygienic and Medical Treatment of Children. By Thomas Morgan Roach, M.D., Professor of Pediatrics, Harvard University. Fifth Edition. Rearranged and Rewritten. Illustrated. Half Leather. Pp. 1000. Price, \$2.25 per volume. Philadelphia and London: J. B. Lippincott Co., 1907.

This work has been revised to bring it up to the standard required by recent advances in this department. This has necessitated the rewriting of a considerable portion of the book and the careful revision of the other articles. The book retains the practical as well as scientific character which rendered the previous editions so helpful to practitioners as well as to students. The illustrations have been increased by a number of new photographs and radiographs and one new colored plate.

A GUIDE TO DISEASES OF THE NOSE AND THROAT AND THEIR TREATMENT. By C. A. Parker, F.R.C.S., Surgeon to the Throat Hospital, Golden Square, London. W. With 255 illustrations. Cloth. Pp. 624. Price \$5.00 net. New York: Longmans, Green & Co., 1906.

This work is for students and practitioners who take courses at special hospitals for diseases of the throat and nose and is the outgrowth of the author's lectures at the Throat Hospital. Section I is devoted to methods of examination of the upper respiratory tract, local treatment, and the general principles governing operations in this region. Section II on complications of the upper respiratory tract in relation to general

medicine, while Section III, nearly a third of the volume, is devoted to the nose. The use of the Heryng lamp for transillumination of the antrum is illustrated with a colored plate. On the subject of spurs and deviations of the septum the author gives an unbiased description of various operations, including several by American rhinologists. Diseases of the throat and larynx are grouped in two large sections of the work, which concludes with an appendix on the notification and isolation of fibrinous rhinitis.

EYE INJURIES AND THEIR TREATMENT. By A. Maitland Ramsey, M.D., Fellow of the Faculty of Physicians and Surgeons, Glasgow. Illustrated. Cloth. Pp. 210. Price, \$6.00. New York: The Macmillan Company, 1907.

This book is based on the author's graduate course of lectures on this subject. He very modestly suggests in his preface that the book is suitable particularly for the general practitioner who requires a pithy presentation of cases, whereas it is a work that any ophthalmologist may read with profit. The main feature of the book is its purely clinical consideration of the various eye injuries with the appropriate treatment. The stock formulas of the Glasgow Ophthalmic Institution are given in an appendix. The book is very freely illustrated with colored plates and drawings and is printed in large type on heavy paper. Dr. Ramsey's large practical experience in the care of eye injuries makes his views invaluable and we heartily recommend his book.

TEXT BOOK OF MATERIA MEDICA FOR NURSES. Including Therapeutics and Toxicology. By G. P. Paul, M.D., Attending Physician to Samaritan Hospital, Troy, N. Y. Cloth. Pp. 242. Price, \$1.60 net. Philadelphia: W. B. Saunders Co., 1907.

Paul's materia medica for nurses is practical in that it deals chiefly with the indications and contraindications for the various drugs, and gives their doses. Part IV, on the "Newer Medicinal Agents," as it deals with the new synthetics, the use of which is not clearly defined, might well have been omitted. Part V, "Practical Therapeutics," deals with hydrotherapy, including baths, gastric lavage, enteroclysis and hypodermoclysis, hypodermic medication, antiseptics and disinfectants, disinfection, topical medication, including application of heat, stupes, poultices, cupping, counterirritation and rectal alimentation, antitoxins and serums.

TEXT BOOK OF EMBRYOLOGY FOR STUDENTS OF MEDICINE. By John Clement Helsler, M.D., Professor of Anatomy in the Medical College, Philadelphia. With 212 illustrations. Third Edition. Thoroughly Revised. Cloth. Pp. 432. Price \$3.00 net. Philadelphia and London: W. B. Saunders Co., 1907.

In order to be in consonance with existing views, the text of this work has been revised thoroughly and in many instances whole chapters have been rewritten, such as the sections dealing with the ovum, the spermatozoon, blastodermic vesicle, the vascular system, ductless glands, pancreas, kidney, spinal cord, spinal column and the musculature. The text is concise and yet sufficiently full for a text book to be used by the student as well as by practitioners. All the good features of the previous editions have been retained and many new ones added.

A SYSTEM OF SURGICAL NURSING. With an Appendix Containing Useful Formulas, Emergency Drill, Etc. by A. N. McGregor, M.D., F.R.F.S.G. Cloth. Pp. 654. Price 98c net. Glasgow: David Bryce & Son.

A volume of more than 500 pages might be considered rather extensive for the elucidation of only one portion of the work of the nurse, but the book is well written, easy to read, well arranged, and, despite the size, not diffuse. It takes up systematically the qualifications of nurses, principles of surgical treatment, sepsis, asepsis, etc., general considerations of disease and repair processes, instruction in the practical details of ward work, preparatory and postoperative treatment of patients and working instructions.

ANATOMY FOR NURSES. E. R. Bundy, M.D., Member of the Medical Staff of the Woman's Hospital, Philadelphia. With a glossary and 101 illustrations, 34 of which are colored. Cloth. Pp. 272. Price \$1.75 net. Philadelphia: P. Blakiston's Son & Co., 1906.

This work is written in simple language and is fairly well illustrated. The chapter on foods and digestion seems slightly out of place in a text book on anatomy and is so brief and superficial that it might well have been omitted.

Miscellany

Assay of Pepsin—Cowie and Dickson (*Pharm Jour*, Feb 23, 1907) worked out a new method of assay of pepsin which determines not simply its solvent power on albumin as in ordinary methods, but rather its actual peptonizing power, which they think is a better measure of its therapeutic efficiency. The process depends on the depth of color given by the biuret produced by the peptone formed in four hours from a given weight of dry albumin by a definite amount of the pepsin to be tested. The color is compared with a solution of potassium permanganate which corresponds in color with the biuret produced from a known weight of peptone. A control experiment must be carried out with the pepsin and water without the addition of albumin. The difference between the number of cubic centimeters required to match the color produced in the two tests corresponds to the amount of peptone actually produced by the digestive action of the pepsin. The method is recommended as giving results that are sufficiently near those obtained by standard methods to give a very good idea of the power of a pepsin. It can be carried out in a comparatively short time and requires no special apparatus. The authors have tried the xanthoproteic reaction by boiling the proteid with nitric acid and then adding excess of ammonia, but found it impossible to measure the differences between the depths of color by any standard yellow solution. At the meeting of the Pharmaceutical Society of Great Britain, at which this paper was read, Mr Dott expressed doubts as to whether or not the solvent power of pepsin as given by the ordinary methods of assay did not represent the therapeutic efficiency nearly enough for practical purposes. Mr Cowie said that it would be advantageous if a uniform process of assay were adopted by the various nations. As America supplies most of the pepsin used in Great Britain it is desirable, he said, that the British process should be similar to that of the U S Pharmacopein.

An Injection Fluid for Preserving Cadavers—An excellent injection fluid for preserving cadavers can be made of equal parts of alcohol, glycerin and melted phenol (carbolic acid) crystals. This fluid, the formula for which has been furnished us by Dr Burton D Myers, professor of anatomy in the Medical Department of the University of Indiana, is made as follows. White crystalline phenol is preferred though the straw colored product will do just as well, but it is not much cheaper. Should the black crude phenol be used blue injection fluid must be used for the arteries, as red lead would be decolorized. White crystals do not seriously affect the color of the red lead. The alcohol should be used in about 95 per cent solution. All the used 95 per cent and 80 per cent alcohol from the histology and neurology laboratories may be saved, this should be filtered and mixed with enough unused 95 per cent alcohol for the injection fluid. The phenol costs from 23 to 24 cents a pound, the glycerin from 16 to 17 cents a pound and the alcohol about 60 cents a gallon. The fluid of this formula thus costs about \$1.42 a gallon. While this is, of course, more expensive than the arsenic and formalin compound, the advantages are well worth the difference in cost. It does not harden and stiffen the tissues as does formalin, there is never any infection from a cut received in the dissecting room, and the tissues, even the finger tips, toes, nose, etc., do not dry out even after weeks of exposure. When cadavers are brought in they are placed on a table and scrubbed, then, as there is no chance of decomposition, there is no odor except that of the phenol. The odor of decaying flesh, so common in dissecting rooms, is entirely absent, and the worst hindrance to good work has been removed.

A Medical Senator Pleads in Favor of Absinthe in France—Belgium has recently prohibited the manufacture and sale of absinthe in that country, and some cantons in Switzerland have likewise taken drastic measures against it still more recently. The medical profession in France has long been striving to restrict the use of absinthe in France, and the group of medical members of the houses of parliament has been agitating the question with renewed energy during the last few months.

The treasury department is strongly against any measure tending to reduce the present income from the internal revenue, and the minister at the head of the department does not hesitate to proclaim openly his hostility to any measure that would create at once a deficit of \$12,000,000. An article in the *Presse Méd*, page 137, remarks that more money is paid out annually to the hospitals, asylums and almshouses on behalf of the victims of absinthe than the entire revenue from this source amounts to. The superintendent of the Ville Evard asylum states that out of the average of 550 alcoholics annually in the institution, fully 90 per cent are victims of absinthe. On the other hand, the representatives in parliament of a certain district where the manufacture of absinthe is the principal industry, are making a strong stand against its suppression. The senator from this district is a physician, and he admits that cheap absinthe is a vile poison but proclaims that the absinthe made in his district is so pure and made of such delightful ingredients that high grade, expensive absinthe like this should not be regarded as injurious. He says that the standard of health in his district is above the average and epilepsy is unknown, although every one drinks absinthe. He pleads earnestly for the few thousands of his voters who live by absinthe forgetting the many more thousands who die by it every year—surely a very strange stand for a physician to take.

Erroneous Ideas About Poisonous Reptiles—Popular opinion attributes to nearly all reptiles more or less poisonous properties. The more formidable or repulsive the reptile the more likely it is to be associated in the popular mind with the possession of venom. In the case of the Gila monster, investigation has failed to bear out the preconceived notion of its dangerous character. Although some evidence has been adduced of the occurrence of sickness and even death after the bite of this reptile, experiment has shown that its saliva is possessed of only very feeble toxic properties, and that it has neither poison glands nor fangs, so that it can not envenom a wound in the manner of the poisonous snakes. Dr G Goodfellow, in the *Scientific American*, March 30, 1907, refutes the evidence recently adduced to show the poisonous character of wounds inflicted by this reptile, especially in two cases occurring in Arizona with the history of which he states he is entirely familiar. The first patient died from acute alcoholic poisoning grafted on chronic alcoholism. The second patient had a very sore finger which resulted apparently from the cauterization and not from the bite. Dr Goodfellow has himself been bitten by the monster, but has seen no consequences different from those usual in case of a lacerated wound. It is probable that some of these cases are aggravated by the unnecessary active local treatment and the injudicious dosing with alcoholic liquids. If Dr Goodfellow's conclusions are correct, such wounds should be treated as ordinary lacerations; no special constitutional treatment is required.

Tapeworm from a Cat—Pollak recently reported at a meeting of the local medical society in Vienna the case of a child of six months affected with tenia. For about 4 months small greenish, gravid objects resembling cucumbers about 1x2 cm. in size had been observed in the stools, and the microscope revealed that they were links of the *Tenia cucumerina* common in cats and dogs. The family had no cat or dog but it was remembered that three weeks before the first appearance of the links in the stools the child had been taken to visit a friend and had lain on a bed with the friend's cat. There were no appreciable symptoms in the infant from the presence of the tenia. This form of tenia passes through the cysticercus stage in dog flesh and dog liver. Only 20 cases are on record of its invasion of man but in most of these severe symptoms were observed convulsions and intestinal disturbances. In the affected animals it frequently induces diarrhea and fits or pseudo rabies.

The Study of Dietetics—The study of the association of foods in health as well as in disease is not only for the physician but extremely profitable to all concerned. It is a science which appetite may be induced to take the trouble to study, and the attending physician a competent diet which will appeal to the patient's point not to be overlooked.—*Medical*

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and methods of treatment for the diseases seen especially in every-day practice Contributions will be welcomed from our readers]

Dosage for Children

YOUNG'S METHOD

This is easily remembered and is a good rule for children over a year old. It is Add 12 to the age and divide the age by the result. For example, for a child of 2

$$\frac{2}{2+12} = \frac{1}{7}$$

COWLING'S METHOD

According to this method the dose for a child is obtained by dividing the number of the following birthday by 24. For example, at 2 years $3-24 = \frac{1}{6}$

CLARK'S METHOD

This rule, although accurate, is not very practical. According to Clark, the proper dose is in proportion to the weight of the individual. Assuming 150 pounds as the average weight for which the dose is 1, then the proper dose will be in the same proportion to 1 as the patient's weight to 150. Therefore, if the weight be divided by 150, the resulting fraction represents the proper part of 1 for the dose in that particular case. For example The proper dose for a baby of 10 pounds would be $1/15$ ($10-150 = 1/15$)

Administration of Hypnotics in Tablets

The tablet as a form for the administration of medicines has many advantages since it combines exactness of dosage, convenience in handling and pleasantness in administration. It is apt to be forgotten, however that all medicines can not be used in this form. Very volatile drugs are manifestly excluded, and salts which irritate the stomach should not be administered in tablet form, unless the tablet is first crushed and dissolved. Difficultly soluble drugs may escape absorption altogether, or their action be much delayed if given in tablet form. The varying degree to which the compression is carried permits of marked variations in the readiness of disintegration and accounts for many variations in the action of the same remedy. It is not an uncommon experience for tablets to be found unchanged in the feces. When a drug is in soluble there is no occasion for administering it in tablet form unless for sake of convenience. In such a case the patient should be instructed to crush the tablet to a powder before taking it.

W. Kohn (*Medizinische Klinik*) calls attention to the disadvantages of the tablet in administration of hypnotics. It is important for the success of a hypnotic that it be promptly absorbed, and thus can best be secured by giving it in solution. The difficult solubility of several of these remedies requires that special precautions be taken to secure solution. If the medicine be taken into the stomach in a tablet it is apt to remain some time undissolved, and hence unabsorbed and inactive, even if a quantity of warm water be taken after it. The remedy may be so gradually absorbed that its hypnotic effect may not appear, the preliminary stage of excitement only being reached. The frequent experience that a remedy does not act until the next day or the succeeding night is probably due to imperfect solution of the drug.

Another accident that may arise in consequence of the irregular absorption of medicines in tablet form is cumulative action. Kohn believes that the unfavorable results noted by some observers in the use of hypnotics arise from the fact that an additional and perhaps increased dose was given before the first had been excreted although due time had been allowed to intervene between the doses. Kohn has found by experience that the administration of a hypnotic in solution secures a quicker effect and as the medicine is all absorbed in a

short time, the occurrence of a tired feeling on awakening is avoided. Another advantage is that the desired effect can be obtained with a smaller dose—four fifths as large an amount generally being sufficient.

Laxatives, Cathartics and Purgatives

The following formula for a laxative pill is recommended by Shoemaker

R	Extracti rhei		
	Pulveris jalapae comp, aa	gr xx	1 3
	Hydrargyri cum creta	gr xl	2 6
	Extracti belladonnae fol	gr iv	26

M Ft pilulae No xx Sig One pill at bedtime

In acute nephritis Croftan recommends evacuating the bowel with castor oil or cascara sagrada. From 2 to 8 grains (0.12 to 0.5) of the extract of cascara may safely be given or of the fluid extract from 10 to 15 minims (0.6 to 2). In this disease Croftan states that saline purgatives must be avoided, as most salts irritate the kidneys or are eliminated with difficulty by the kidneys when these organs are diseased. He asserts that calomel and all drastic purgatives should be used only as extreme measures in emergency cases.

When a simple laxative is necessary the elixir of cascara sagrada (Elixir rhamni purshianae, N F) is very efficient.

R	Fluیدextracti rhamni purshianae aromatici		
	Elixir aromatici, aa	f3i	30

M Sig One teaspoonful at bedtime

When a more powerful preparation is needed, the compound elixir of cascara (Elixir rhamni purshianae compositum, N F), may be used.

R	Fluیدextracti rhamni purshianae aromatici	f3ii	8
	Fluیدextracti sennae	m xlviij	3
	Fluیدextracti juglandis (N F)	f3i	4
	Elixir aromatici	f3xii	48

M Sig One teaspoonful at bedtime

The above prescriptions are useful in the constipation of pregnancy in which saline cathartics are seldom indicated. In these cases pills of belladonna, aloin and strychnin may also be used. The National Formulary contains formulas for several such pills.

R	Aloin	gr 1/2	03
	Resinae podophylli	gr 1/8	008
	Extracti belladonnae fol	gr 1/4	01

Ft. pilula Sig One such pill as often as necessary

R	Aloin	gr 1/5	012
	Strychninae	gr 1/120	00054
	Extracti belladonnae fol	gr 1/8	008

Ft pilula Sig One such pill at bedtime when necessary

R	Aloin	gr 1/5	012
	Strychninae	gr 1/120	00054
	Extracti belladonnae fol	gr 1/8	008
	Extracti rhamni purshianae	gr 1/2	03

Ft pilula Sig One such pill at bedtime when necessary

For children calomel and the syrup and tincture of rhubarb answer the purpose in most cases. If castor oil is particularly indicated H. B. Sheffield, New York, recommends the following emulsion.

R	Olei ricini	f3i	30
	Olei menthae piperitae	m v	3
	Sacchari	3i	4
	Mucilaginis acaciae		
	Aqua aa, q s ad	f3i	60

M et ft emulsum Sig From 2 to 4 teaspoonfuls at a dose, according to the age of the child.

Sheffield states that Rochelle salts with a little aromatic spirits of ammonia, glycerin and water constitute a pleasant mixture. Podophyllin and aloin, he states, are best prescribed in suppositories or cacao butter. This authority also says that it is well to remember that an enema often obviates the necessity for drugging.

The following has been recommended in obstinate constipation

R	Fluیدextracti rhamni purshianae	f3i	30
	Fluیدextracti belladonnae	f3i	4
	Tincturae nucis vomicae	f3ii	8
	Syrupi		
	Aqua aa, q s ad	f3i	120

M Sig One teaspoonful thrice daily

The following pills have also been recommended

R Extracti colocynthis comp	gr xii	78
Extracti belladonnæ fol	gr ii	13
Extracti gentianæ	gr vi	4
Olei cari	gtts iii	10

Ft pilulæ No vi Sig One pill at bedtime

R Resinæ podophylli	gr ii	13
Quininæ sulphatis		
Extracti aloes, ãñ	gr viii	5
Fellis bovis	gr xvi	104

Ft pilulæ No vi Sig One or two pills at bedtime

Potter recommends the following castor oil emulsion for children

R Olei ricini		
Glycerini, ãñ	f3i	30

Asthma in Infants and Children.

Cautley, in the *Clinical Journal*, London, states that the prophylactic treatment consists in bringing up predisposed children in the most suitable manner as regards hygiene, diet and prevention of catarrhal conditions. The body should be kept warm and the apartments cool. A high dry air (mountain region) is more suitable for these patients than the seaside. When there is much catarrh, however, it is more important to choose a warm dry climate, or seaside air and sandy soil, with the object of benefiting the catarrh. High altitudes are unsuitable for emphysema.

The diet should be simple and nutritious and should consist of small regular meals, avoiding all meat extracts and excess of carbohydrates. Fruit may be given liberally. The bowels should be kept open.

All local sources of irritation should be attended to, and adenoids or enlarged tonsils should be removed.

During a paroxysm of spasmodic asthma a warm bed in a room with open windows may be all that is necessary in mild cases. In more severe ones some of the following methods may be adopted. In order to induce general vasodilation give a hot water or vapor bath, apply hot fomentations or turpentine stupes to the chest, administer nitroglycerin, nitrites, or inhalations of amyl nitrite, or give chloral by mouth or rectum, or give alcohol. Constriction of the respiratory mucosa can be induced by inhalation of cold air from ice in a jug or inhaler, adrenalin, 1 in 1000, the fumes of brown paper, nitre paper, the leaves of stramonium, or belladonna or hyoseyamus.

Most of these remedies are irritating, unsuitable and injurious in the catarrhal asthma of infants, in which more benefit is derived from the inhalation of terebene or creosote.

An emetic is often useful at the onset of an attack, and for this purpose the syrup or the wine or powder of ipecacuanha can be given. In older children unable to swallow, one tenth of a grain (0.006) of apomorphin may be given subcutaneously. Emetics help the child to get rid of mucus and also act as cardiac depressants. Other remedies which may be mentioned are belladonna by the mouth and atropin or pilocarpin subcutaneously, counter irritants to the chest dry cupping and occasionally bleeding. Morphine administered subcutaneously, is useful in bad attacks, but should very rarely be employed for children.

For the prevention of the nocturnal paroxysms antipyrin, acetphenetidin (phenacetin) or bromide may be given at bedtime.

Between the attacks treatment must be directed to the general health. A course of potassium iodid or syrup of the iodid of iron and cod liver oil is advisable. Arsenic is beneficial in cases in which there is a tendency to glandular enlargement while strychnin and cinchona form useful tonics. Cauterization of the nose is another measure which may be tried in this condition.

As a general principle it is infinitely more important to attend to the general health of the child, to prevent erroneous methods of feeding to remove local sources of irritation, and to cure the catarrhal tendency, than it is to rely on measures for relieving or cutting short the paroxysms.

Medicolegal

Towns Can Not Remove Members of Boards of Health.

The Supreme Judicial Court of Massachusetts, in the case of the Attorney General vs Stratton and others, a proceeding in the nature of quo warranto to require the respondents to show by what warrant and authority they exercised the office of members of the board of health of the town of Swampscott, holds that it could not be maintained. It says whatever the rule may be in reference to municipal corporations in other parts of the country, it is of the opinion that, in the cities and towns of Massachusetts, there is no power to remove public officers except that which is given by the statutes. In Massachusetts the election of public officers, their removal from office and the filling of vacancies have been the subject of elaborate legislation. But there is no provision for the removal of members of the board of health in towns. In the absence of any such provision the court is of the opinion that they can not be removed by a vote of the town, either with or without a hearing before the town or a committee thereof.

Damage for Injury Causing Loss of Bowel Control.

The Court of Appeals of Kentucky says, on the appeal of Louisville Railway Company vs Bohon, a personal injury case brought by the latter party that the plaintiff testified that after she had been thrown to the ground while attempting to alight from a street car, she was confined to her bed about two weeks, that the physician visited her during this time quite frequently, that she was injured not only by a cut in her scalp, but that there was an injury to her spine, affecting the lower portion thereof, and that at the time of the trial—which was a year or more after the date of the injury—she was still suffering from the effects of the injury. Her physician testified that he had visited her and prescribed for her at her home and at his office 50 or more times during the course of that year. He further testified that the injury was such as to leave her in a most distressing and unfortunate condition, that the injury to her back so affected the nerves of the back as to produce partial paralysis thereof, and caused her to lose control of her bowels, and that this trouble was traceable directly to the injury, that he had been her family physician for some seven years or more and that she had no other injury than the one occasioned by the fall from the car, so far as he knew. That for some time after the injury the nerves controlling the bladder were also affected but that at the date of the trial she had in a measure recovered from this trouble but that she was still unable to control her bowels. The trial resulted in a verdict of \$3,000 for the plaintiff and the judgment therefor is affirmed. As to whether this injury was permanent or not the court states that it can not say, but that even if it was not it is of the opinion that the damages awarded were not excessive.

Proving Being Physician in Action for Services.

The Supreme Court of Montana says that the case of *Legat vs Gerrick* was brought to recover a balance of \$100 for professional services rendered for the defendant by the plaintiff a physician. The physician obtained a judgment in the district court which is affirmed although it was urged that the evidence was insufficient to sustain the decision of the lower court in that there was not any evidence offered on behalf of the plaintiff to show that the plaintiff held a certificate granted by the state medical board of the State of Montana entitling him to practice medicine.

If the fact affirmatively appeared that the plaintiff rendered services were rendered the plaintiff then the Supreme Court says if recovery would be raised directly.

appear, the only question presented here was "On whom rested the burden of proof? Was the burden on the plaintiff in the first instance to show that he had such certificate, or was it on the defendant to show that he did not have it?"

The testimony given at the trial on behalf of the plaintiff by a witness named Kremer was "I knew Dr Leggat at that time, and I can state that I knew him to be a physician and surgeon in the city of Butte, and at that time was the city physician." In view of this testimony, the Supreme Court thinks that the presumption followed that Dr Leggat had complied with the law, and that the burden of proof was on the defendant to show that he had not done so. And, in the absence of any attempt on the part of the defendant to make this proof, the court thinks the evidence was sufficient to sustain the decision of the lower court.

The Supreme Court says that after a careful review of the authorities the Court of Appeals of Illinois, in *Williams vs People*, 20 Ill App 92, said "Where the question of license or qualification of a physician arises collaterally in a civil action between party and party, or between the doctor and the one who employed him, then the license or due qualification under the statute to practice will be presumed." *McPherson vs Cheadell*, 24 Wend. (N Y) 15, *Thompson vs Sayre*, 1 Denio (N Y) 175, *Pearce vs Whale*, 5 Barn & Cres 758. The reason for the rule is stated by the same court in the *City of Chicago vs Wood*, 24 Ill App 40, as follows "The reason why the license will be presumed where there is no evidence to the contrary, rests on the principle that, when an act is required by positive law, to be done, the omission of which would be a misdemeanor, the law presumes that it has been done, and therefore the party relying on the omission must make some proof of it though it be a negative."

While there is some conflict in the decisions, the decided weight of authority seems to be in favor of the rule stated above in *Williams vs People*. *McPherson vs Cheadell*, 24 Wend. (N Y) 15, *Jo Daviess County vs Staples*, 108 Ill App 539, *Lacy vs Kossuth County*, 106 Iowa, 19, *Dickerson vs Gordy*, 5 Rob (La) 489, *Lyford vs Martin*, 70 Minn 243, *Cather vs Damerell* (Neb) 99 N W 35, *Rider vs Ashland County*, 87 Wis 160, *Good vs Lasher*, 99 Ill App 653.

The same general rule is recognized by the Court of Appeals of Indiana in *Cooper vs Griffin*, 13 Ind App, 212, but, by reason of a special statute in that state, the contrary rule is upheld.

A somewhat analogous question is presented in an action brought in a court of this state (Montana) by a foreign corporation. It has been held that it is not necessary for the foreign corporation to prove, in the first instance, that it has complied with the laws of this state entitling it to do business here.

Nor does the Supreme Court think that the trial court erred in allowing interest on the amount recovered, its action appearing to be warranted by section 4280 of the Civil Code of Montana, which provides "Every person who is entitled to recover damages certain, or capable of being made certain by calculation, and the right to recover which is vested in him on a particular day, is entitled also to recover interest thereon from that day, except during such time as the debtor is prevented by law, or by the act of the creditor, from paying the debt"—and by the construction given to that section by this court in *Hefferlin vs Karlman*, 29 Mont 139.

Liability of Hospitals and Others for Negligence in Charity Cases—Case of Patient Paid for by County

The Supreme Court of Utah says that the case of *Gitzhoffen vs Sisters of Holy Cross Hospital Association* was brought to recover damages alleged to have been sustained by the plaintiff through the defendant's negligence while he was an inmate of its hospital. The evidence on the part of the plaintiff tended to show that when he was admitted to the hospital he was suffering from gonorrheal conjunctivitis in the second, or purulent stage, and should have had his eyes cleansed every 20 minutes which was not done, in consequence of which total blindness resulted in the left eye, and the sight of the right eye was so impaired as to amount to

substantial blindness. The county paid the defendant for taking care of the plaintiff 41 days, \$41.

The great weight of authority is, the court says, that a charitable institution or corporation is not liable for the negligent acts of its nurses or other employees, if it has not been guilty of negligence in selecting them. To a corporation or organized for profit the doctrine of respondent superior (the superior or master must answer) fully applies, and the corporation is made liable for the negligent acts of its employees done in the discharge of its business and within the scope of the servants' employment.

In this case, however, it was in effect urged that, notwithstanding the general character of the defendant as to its being a corporation for gain, nevertheless the actual relation existing between it and the plaintiff was merely charitable, and hence the same principle of the law should be applied to the case as is applied to charitable institutions, only making it liable for its negligence in the selection of the nurse. This position was taken from the assumed facts that the plaintiff was an indigent person, a charge on the county, and as such was placed by it in the hospital for treatment for which payment was made by the county, the plaintiff paying nothing and not agreeing to pay anything. As stated by counsel for the defendant in his brief "There was no contract between plaintiff and the defendant. The contract for his admission to the hospital was between the county, whose charge he was, and the defendant. Under the contract between the county and the defendant, plaintiff, having been sent there, had a right to be in the hospital and to be treated as a patient."

If one, through mere kindness or charity, admits a sick or wounded person to his house to administer aid and comfort to him, and for such purpose selects a physician or servant to attend him, undoubtedly he ought not to be held, nor does the law hold him, liable for the negligence of the physician or servant, unless, as the authorities say, he has been guilty of negligence in the selection of the physician or servant. And, had the defendant so received the plaintiff, and not otherwise, it could not be held liable in any greater degree.

But, if one receives another into his house for the purpose of treating him, and assumes and undertakes to do so, though it may be done gratuitously, there is some force to the position that he should be held liable for the negligence of his servant in the discharge of the duties undertaken and assumed by him, on the principle of law that, if a person actually undertakes and enters on the execution of a particular work, it is his duty to use reasonable care in the manner of executing it, whether done by himself or through his servants. Applying the principle, there is force to the argument that the defendant, having received the plaintiff into its hospital, and having assumed and undertaken to treat him, it thereby assumed the duty of using reasonable care in so doing. But the court need not, and does not, rest the determination of the case on this principle.

It was alleged in the complaint that the defendant received the plaintiff into its hospital for hire. The defendant in its answer, while denying that it received the plaintiff under any direct contract or agreement with him, yet admitted that it received him for treatment under a contract with the county for which it was paid by the county. The admission had the effect of precluding the defendant from making the claim that the plaintiff was received and treated by it through mere charity, for the court can not well see how the defendant could admit that it received the plaintiff for treatment under contract with the county for hire, and then claim that it received the patient gratuitously. No claim was made that the payment received by it was not made or received as compensation, but only as a donation or contribution to the defendant determined by the ability of the patient or the county to give and not on the value or cost of services rendered.

If the defendant agreed with the county to receive the plaintiff for treatment for a price which the county was willing to pay, and the defendant to accept, the court can not see what difference it made that the relation between the county and the plaintiff was charitable, any more than if an individual through mere kindness toward the plaintiff had contracted

As to the condition of the plaintiff's eyes at the time of his admission to the hospital, the yielding of the disease to treatment, the physician in charge of the plaintiff, the directions given by the physicians to the defendant and its nurses with respect to the treatment, and as to what transpired at the hospital, the evidence was conflicting. The case ought to have been submitted to the jury, and the trial court erred in not submitting it.

30 **Absorption of Peritoneal Cavity**—Buxton's article may be summarized as follows: Bacteria, when injected into the peritoneal cavity even in minute doses, reach the circulation in a few minutes by way of the lymphatics of the diaphragm. If these results are applied to man, then the Fowler position is indicated to avoid a rush of bacteria toward the diaphragm, and flushing of the abdominal cavity is not indicated. Rabbits frequently die from acute intoxication in about two hours after injection into the peritoneum of living typhoid bacilli. May not, then, asks Buxton, many deaths from shock after operation for perforation accompanied with irrigation be due to a similar cause?

31 **Brown Tail Moth Dermatitis**—Tyzzer says that the lesions are produced by the penetration into the epidermis of peculiarly modified microscopic hairs, the netting hairs, which are sharply pointed and barbed. The other hairs of both the caterpillar and the moth do not produce any dermatitis. The netting hairs, which from their shape are perfectly adapted for penetration, possess in addition an irritating substance which is undoubtedly an important factor in the production of the dermatitis. This substance may be destroyed by heating the netting hairs at 115° C. or it may be extracted from them by certain solvents such as dilute solutions of alkalis at room temperature or water heated to 60° C. Netting hairs inactivated by either of these measures produce no more than a slight redness when rubbed into the skin and probably act then merely as foreign bodies. The dermatitis produced by the netting hairs is of two types dependent on the number of these elements penetrating a given area. The severe type is usually due to actual contact with caterpillars, the milder scattered rash is due to netting hairs blown in the air and lodging on the skin or on the undergarments as they hang drying. The pathologic process in the skin consists of necrosis of

the epidermal cells around the netting hairs, the formation of spaces or microscopic vesicles in the epidermis at the site of injury, and inflammatory changes about the vessels of the corium. (See editorial comment, page 1436.)

33 **Uricolytic Enzyme**—The results of Austin's investigation may be summed up as follows: All alkalis, even the weaker ones, at brood oven temperature split uric acid, an action which almost invariably increases as the temperature rises. The destructive action of the alkali used for the solution of uric acid is not uniformly increased by the addition of organic extracts isolated by the method of Rosell, which is supposed to isolate an active enzyme if such exists. Among the products of splitting by both the alkali alone and the alkali in conjunction with organ extracts, oxalic acid is rather uniformly found, urea and allantoin not at all. It is very difficult to isolate an extract of organs which does not contain purin bases, which are readily converted to uric acid at brood oven temperature by xantho oxydase, thereby obscuring the results obtained by isolation of the remaining acid. There is no evidence of the reversible action of uricolytic enzyme if such exists. Unless some solvent other than an alkali is found for uric acid, it will be difficult to separate the destructive action of the alkali from that of any enzyme which may be present.

48 Case of Ectopic Pregnancy D. S. Lamb, Washington

42 **Fractures of Shaft of Femur**—White recommends wiring especially in cases of fracture in the upper third of the shaft and other fractures when perfect apposition is impossible and when union is delayed or vicious. He is firmly convinced that the future treatment of this fracture will be largely operative.

43 **Injury of Cornea**—As the result of the explosion of a pop bottle Lamb's patient sustained a very severe injury of the cornea. The wound extended from above the sclerocorneal margin, including the ciliary body, across the center of the cornea nearly to the opposite sclerocorneal margin. The anterior chamber was absent and the iris filled the wound from end to end. Rest in bed, a pressure bandage and the instillation of eserin sulphate constituted the treatment employed. The patient made an excellent recovery, his distant vision without glasses being 6/6.

45 **Phenol in Erysipelas**—Randolph is convinced that in the application of pure carbolic acid, controlled by alcohol, used before secondary infection of the deeper tissues has occurred we have almost a specific for erysipelas. He reports two cases in which this method of treatment was successful. In one of these cases the disease was communicated by a barber.

Louisville Monthly Journal of Medicine and Surgery

49 *Cases of Tuberculosis Treated with Serum S. W. Holloway, Louisville

50 Diagnosis and Treatment of Pulmonary Tuberculosis F. M. Walker, Louisville

40 Serum in Tuberculosis—Holloway believes in the efficacy of the serum treatment of tuberculosis and reports 15 cases to illustrate the benefits he has derived from its use. In the early cases the best results were obtained, the next, in cases somewhat advanced, but not infected. Cases of mixed infection were apparently made worse, and the far advanced cases showed no reaction but progressed as under other methods of treatment. Medicinal treatment was eliminated as far as possible, and no fixed diet was insisted on. In every case the diagnosis was confirmed microscopically.

Journal of Cutaneous Diseases, New York.

March

- 51 *Syphilitic Alopecia H G Klotz New York
52 *Phagedenic and Serpiginous Ulcers and Infective Granulomata. W T Breakey Ann Arbor Mich.

51 Syphilitic Alopecia—Klotz is of the opinion that alopecia is not a common or regular symptom of the early stages of syphilis, although a certain number of cases may be accompanied by a diffuse loss of hair, varying in degree, similar to that observed after other infectious diseases. There is, however, a form of alopecia that occurs almost exclusively in syphilis, and it is so characteristic as to be diagnostic of syphilis, either acquired or hereditary. It occurs in the form of ill defined, irregular, small, sometimes coalescent patches of baldness distributed principally over the back and upper portions of the scalp and giving it a mangy or moth eaten appearance. It generally follows a very tedious course, although terminating in restoration of the hair.

52 Phagedenic and Serpiginous Ulcers—Breakey reports a case of this kind which is unique mainly because of its duration. The diagnosis was somewhat uncertain because the lesions resembled the ulcerating granulomata. The ulcer was situated across the posterior side of the right thigh.

54 Successes and Failures in Intubation H Dupuy, New Orleans
55 Case of Dermatobia Noxialis J B Elliott Jr New Orleans

53 Operative Surgery of Spine and Cord—Bickham pleads for greater ability on the part of the surgeon to diagnose his own neurologic cases, which involves a broader knowledge of physiologic, pathologic and clinical phenomena of nerve functions and nerve conditions. He says that in the absence of such ability and in the present status of limited knowledge of the cord in health and disease and considering the equivocation of many clinical phenomena, in many cases, the only possibility of ascertaining the condition of the cord and, consequently, of giving a patient the best chance for recovery is by exposing the cord, seeing and palpating it. He also pleads for the freer application of surgical measures to a large variety of spinal lesions, at the same time laying stress on the need of more prompt surgical and sufficiently radical action in those cases in which surgical action is called for at all. He urges the substitution of the osteoplastic method of resection in exposing the spinal cord and canal for the older form of exposure by laminectomy.

61 Treatment of Patients and Methods of Sterilization at St Mary's Hospital Rochester Minn S C Fay Selma Minn
62 Present Status of Orthopedic Surgery R L James Seattle
63 *Gonorrheal Eriothitis in the Male J W Thomas Seattle

56 Plea for Better Knowledge of Materia Medica—Marley urges that physicians post themselves better than they do with regard to the physiologic action of drugs. After a thorough knowledge of diagnosis it is essential to know what medicines are indicated in a given case. Marley says that

medical colleges should devote more time to the teaching of materia medica and therapeutics.

58 Cataract Produced by Electricity—Stillson reports three cases of opacities in the crystalline lens which were caused by electricity and which closely resemble cataracts caused by lightning. In the first case there is a complete loss of vision, and the only abnormality in the eyes is a cloudiness of the anterior portion of each lens the cloud resembling small dust particles just under the anterior capsule. In the second case numerous spots appear in the anterior surface of the lens just under the capsule and composed of dots and interlacing lines. The fundus was normal and vision equaled 8/10. The third case was similar to the second. The current causing these lesions was an alternating one of 20 000 and 30 000 volts.

59 Treatment of Acute Septic Peritonitis—Willis outlines his treatment as follows. In the majority of cases the cause should be removed by operative interference, which should cause as little traumatism as possible to the peritoneum, saline flushing should be practiced and adequate drainage provided. Firm dressings should be applied to give rest to the bowels. Nothing should be given by mouth except water. Gastric lavage should be used as often as necessary, even once an hour. Saine solution should be given by rectum and, if necessary, subcutaneously. If necessary, nutritive enemata should be given. Exceptions to the operative portion of the treatment are cases which are too far advanced, thus requiring precisely the same treatment without operation, and some cases which develop from the pelvic organs of the female. The points which Willis emphasizes are the absolute necessity of avoidance of all kinds of nourishment by mouth, and the frequent use of gastric lavage.

63 Gonorrheal Peritonitis in Male—Thomas reports two cases of gonorrheal peritonitis occurring in the male. In one case it is assumed that the infection came from the seminal vesicles. The second patient denied all possibility of gonorrheal infection.

70 Reverse Antrum Bone Forceps in Antrum Surgery I Ostrom Rock Island Ill

64 Turbinectomy—Yankauer describes a new method of operating for hypertrophy of the turbinates. The operation consists of two stages. 1 The excision of the hypertrophied tissue, 2 the suture of the wound. The latter is the essential feature of the operation and in order to carry it out successfully special instruments are required. These and the steps of the operation are described in detail. The procedure has been employed successfully in 14 cases of hypertrophy of the inferior turbinate.

65 Suppuration of Accessory Nasal Sinuses—Halle summarizes his paper as follows. 1 In every case of accessory sinus empyema physiologic breathing is first of all to be established. 2 In every case a cure should be attempted by establishing a blood drainage opening into the nose. 3 In a large number of cases perhaps in most cases the frontal sinus also can be opened from within easily and without danger if the proposed method be followed. 4 The external operation is to be resorted to when the discharge is continuously profuse or of long duration, also when it is a danger. 5 The after treatment in such cases is to be conducted from within unless the complete obliteration of the cavity by means of granulation is to be effected.

66 Pharyngo mycosis—Quinlan reviews the clinical history of this condition the etiology of which is not definitely established.

68 Fibrous Atresia of Nares—In the case reported by Abraham a fibrous circular web was situated at the entrance of the mucocutaneous surface of the nares.

opening was situated near the center of the web, and through this the patient attempted to breathe. The web was removed under local anesthesia. A trauma, with a baseball bat, was the cause of the condition.

- 80 Differential Diagnosis Between Headaches of Ocular and Nasal Origin. M. Black Denver

71 Severe Vertigo from Eyestrain.—Dixon reports two cases of vertigo in which relief was given by the wearing of glasses.

73 Self Enucleation of Eyeball.—Noyes reports the case of an insane woman, 65 years old, who forced her finger back into the socket of the eye and deliberately pulled the organ out. About 3 cm. of the optic nerve were attached to the eye. The woman attempted to enucleate the other eye, but only succeeded in causing blindness. It seems that the removal of the eye was prompted by an irresistible impulse, its origin being an hallucination of hearing. The patient was very religious and thought she heard a voice say "If thine eye offend thee, pluck it out."

75 Diagnosis of Conjunctivitis.—Clothier emphasizes the importance of a careful bacteriologic examination of the ocular secretions when attempting to make an accurate diagnosis of conjunctivitis.

79 Primary Gumma of Sclera.—The patient whose case is reported by Jones was 36 years of age. Occupying a position about 3 or 4 mm. above the cornea was a diffuse, slightly nodulated swelling, very red and inflamed, in the center of which was a bright yellow spot. It was underneath the conjunctiva, and apparently located in the sclera. From the course of the disease and its reaction to specific treatment Jones considered it a case of primary gumma of the sclera.

82 Pneumonia.—Johnston details the results of an analysis of 100 cases of pneumonia, made for the purpose of determining the frequency of the so-called classical symptoms and signs. In this series there were 16 cases of apical pneumonia. Crises occurred in 72 cases from the fifth to the eleventh day, 31 per cent of these occurring on the ninth day. Twenty-four of the patients died. Herpes was noted in many of the cases. In 87 per cent of the cases there was pain over the area of lung involved, abdominal pain was present in 2 per cent., pain on both sides in 1 per cent., pain in the back and legs in 3 per cent., and in 7 per cent. no history was obtained. In 53 per cent the temperature was 103 F. or higher, while in 29 per cent it was 102 plus. In 39 per cent the pulse rate was 120 or more, while 17 per cent had a pulse rate of not less than 110. Cough was present in all the cases. The character of the sputum was not noted in all the cases, but it was characteristic in 37 in which record was made.

84 Treatment of Pneumonia.—Anders emphasizes the value of hygienic measures and plenty of fresh air in the treatment of pneumonia. Strchnin, whisky and digitalis are recommended in suitable cases and the application of cold compresses to the chest and the reduction of temperature by cold spongings are discussed favorably.

85 Vaccination and Antivaccination.—Lee discusses the statistical government reports of Russia and Germany with reference to the efficacy of compulsory vaccination in the prevention of smallpox. The records are very much in favor of the methods employed in Germany, where vaccination is compulsory.

- 87 *Treatment of Conjunctivitis Trachomatosa Relative to Sequelae. F. P. Parker, St. Louis
- 88 Spinal Irritation. W. T. Marrs, Peoria Heights, Ill.

86 Diet in Gastric Disorders.—Hoxie emphasizes the value of dietetic treatment in gastric disorders and suggests that every practitioner have ready at his disposal a few dietaries which every household can follow out. He says that a great deal may be accomplished by having patients suffering from gastric exhaustion rest for from one half hour to an hour after each meal, especially, if such rest be taken in the open air and sunlight. The electric tub bath, with a sinusoidal current, given when the stomach is empty, acts as a stimulant, and cold douches applied to the spine early in the day and deep massage of the abdomen late in the afternoon are procedures which Hoxie has found useful.

87 Trachoma.—Parker urges early operation in trachoma. He says that if there were more operative treatment combined with local applications in the treatment of trachoma it would shorten the duration of the disease and at the same time lessen the hypertrophy of the conjunctiva, thereby minimizing the danger of complications.

- 92 *Hypertrophic Stenosis of Pylorus in Infant. R. B. Kimball and F. Hartley New York.

89 Anemia Infantum Pseudoleukemica.—Koplik presents a very detailed report of nine cases of this affection, occurring in children ranging in age from 11 to 20 months. Three of the patients died and three improved under treatment. The lowest hemoglobin record was 25 per cent., the highest 65 per cent. In the latter case the leucocytes numbered 96,000, the highest count in any of the nine cases. Careful differential counts were made, as may be seen by consulting the original report.

90 Modified Wet Nursing.—In the plan of feeding proposed by Westcott the human milk serves simply as one ingredient of the bottle mixture. The average yield for the day is apportioned in fairly equal amounts for each feeding, and the total quantity of the bottle is made up according to the needs of the individual case. He has found this method a most helpful aid in convalescence from summer diarrheas in very young infants. The object of this plan of feeding is to secure a food which can be appropriated at once by the starving organism of the infant, and then to continue this until, by gradual increase, the artificial ingredients of the bottle can be fitted to the increasing demands of the infant, so that the human milk can be dispensed with altogether and the thriving infant allowed to proceed on a satisfactory artificial food.

91 Typhoid.—Southworth presents the histories of two house epidemics of typhoid fever in different cities, the connecting link between which was an infant 10 months of age, who, preceded and followed by definite cases of typhoid in his own family, passed through an illness with prolonged but relatively moderate temperature, with gastrointestinal symptoms and a complicating pneumonia, without positive Widal at the time, but after some weeks giving a positive reaction. The infant after a normal temperature for about two weeks, during part of which he was under observation in a hospital, then entered another family and house in which there had been no typhoid, and during his stay there had been only one acute indisposition of a few days' duration, with temperature falling to the normal in two days under local treatment of an edematous and excoriated prepuce. Three weeks after his arrival there two children came down with typhoid, and two weeks

later a third child. Painstaking inquiry revealed no other source of infection. The evidence seemed to point strongly to the infant as the carrier of infection after his convalescence.

92 Hypertrophic Stenosis of Pylorus—Kimball and Hartlev report a case of hypertrophic stenosis of the pylorus, which was treated dietetically for about three weeks, when it became necessary to do a posterior gastrojejunostomy, from which the patient made an uneventful recovery.

1 Kidney Disease—Bradford discusses the diagnosis of certain forms of renal disease, particularly functional albuminuria and nephritis, and also reviews the principles of treatment of Bright's disease. He lays great stress on the importance of never diagnosing the presence of serious renal disease merely on the strength of a urinary examination. He says that this should always be controlled by a clinical examination.

the patient, with special reference to the state of the cardiovascular system and the general nutrition.

2 Albuminuric Retinitis—Jessop describes three cases of typical albuminuric retinitis occurring in a case of parenchymatous nephritis, in one of chronic interstitial nephritis and in one of acute nephritis in pregnancy.

3 Treatment of Syphilis—The general treatment of syphilis, as usually carried out, is reviewed by Pernet, and special reference is made to intramuscular injections of mercurial preparations.

4 Bacteriologic Diagnosis of Cholera—As the result of careful experimentation, Ruffer is of the opinion that it is not advisable to trust to the agglutination test only in the bacteriologic diagnosis of cholera. The test is said to be useful but not specific.

5 Insanity—In this, his third lecture, Savage discusses alcoholism and influenza as causes of insanity, the sexual causes, and the question of an increase in the number of the insane.

7 Lupus Vulgaris—In the case reported by Dewar, the disease had existed for about fourteen years, resisting treatment by cauterization and incision and radiotherapy. The lesions were situated on the left side of the nose over the left malar bone, on the lobe and helix of the right ear, and at the angle of the jaw on the right side. A test injection of tuberculin was followed by a rather violent reaction. The treatment adopted by Dewar was about as follows:

After washing off the scabs with hot water, the lesions were dried, and thin pieces of cotton wool soaked in a 5 per cent solution of cocaine, were applied to the ulcers for a few minutes. On removing these, thin films of cotton wool, soaked in a ten volume solution of peroxid of hydrogen, were left on and kept in position by touching the edges with collodion. Every second day the patient was given an intravenous injection of 15 minims of an ethereal solution of iodoform plus liquid paraffin. Within forty days the patient was cured completely.

12 Acute Infective or Toxic Conditions of Nervous System—In this paper Buzzard discusses acute ascending myelitis, Landry's paralysis and acute toxic polyneuritis.

13 Treatment of Acute Heart Failure—Nothing new is presented by Bolton with reference to the treatment of acute heart failure. He reviews the causes for the occurrence of such a failure and outlines the treatment that is usually adopted.

14 Cerebrospinal Fever—Raw reports two cases which illustrate the impossibility of making an accurate diagnosis between cerebrospinal and acute tuberculous meningitis, especially in time of epidemic, when attention is turned in that direction.

15 Puerperal Septicemia—In 49 cases of puerperal fever, reported by Gordon, there occurred 12 fatalities. 4 of the cases shortly after the patients reached the hospital. The routine treatment of the cases consisted in curettage and vigorous disinfection of the uterus. Anti-tetanic serum was given to 20 patients, the dose ranging from 0 to 200 cc. The usual amount injected was 100 cc. Three of the patients died. Gordon believes that the proper treatment is thorough local disinfection and that only a few drugs are occasionally useful.

by—J

systolic murmur was heard over the precordium, probably due to a defect of the interventricular septum. A radioscopic examination was made and showed considerable enlargement of the bones of the legs, hands, feet and both forearms.

25 Ovarian Grafting—Carmichael has looked into the value of ovarian grafting from the surgical standpoint. He found that in the rabbit the whole ovary may be transplanted with success, but in the majority of cases, about 80 per cent., there was partial degeneration of the ovary. The ovary also may undergo either a fibrous or a cystic degeneration. The germinal epithelium persists in a small percentage of cases. The Graafian follicles and ova persist and mature some months after grafting, but ultimately tend to become cystic. From these observations Carmichael concludes that it is unlikely that the whole human ovary can be grafted with success, but that partial grafting is more likely to succeed, i.e. grafting of the cortical portions of the ovary more especially. Furthermore, part of the ovary may ovulate and preserve its function of internal secretion.

26 Mechanical Dilatation of Cervix Uteri.—Leicester reports 16 cases in which he made use of some form of mechanical dilatation of the cervix in order to effect delivery. In none of these cases was there any untoward effect which could be attributed to the method of dilatation. The instrument used in the first six cases was Boss's model, in the remainder, Preiss's modification of the Boss's instrument. In 7 cases dilatation was resorted to for eclampsia, in 6 for rigid cervix, and in 1 each for induction of labor, placenta previa and hydatid mole. Leicester is of the opinion that these dilators have a distinct place in obstetric practice, but that the number of cases in which their use is indicated is limited.

27 Pregnancy in Women with One Kidney.—The case reported by Ferguson shows that in a patient whose remaining kidney is healthy and has had time to become sufficiently hypertrophied to perform the work of two the strain of pregnancy can be borne fairly well. The patient had, on the whole, less severe albuminuria and less toxic disturbance than many albuminuric primigravidae, both of whose kidneys are known to be organically sound.

34 Neuronophagy—Marinesco reviews what has been written on the destruction of nerve cells by phagocytes. His conclusions are that neuronophagy actually does occur but only when the nerve cells have become degenerated or disintegrated from any cause. Experiments with cauterization of brain tissue, injection of Ipecac powder and transplantation of ganglion cells have convinced him that so long as the nerve

cells remain intact they are respected by the phagocytes, but that dead cells are soon incorporated by the phagocytes. He suggests "necrophagy" as a more appropriate term than "neuronophagy."

36 Bone Tumors in the Skull—Three cases of large bony growths in the frontal bone are described in which operative intervention gave comparatively good results. In the two severer cases the operation was rendered difficult by the danger of involvement of the meninges in an otherwise harmless inflammatory condition in the nose, and also by the difficulty of keeping the wound aseptic when it was necessary to open the frontal sinus. The indications for operation were imperative, as the osteoma was growing fast and had already produced choked disc. There was danger of impending epilepsy, headache, blindness, etc., if the growth, harmless in itself, should increase much more.

37 Subdural Hematoma—Kronlein's patient was a young man who fell on his head. The only symptom at first was headache. On the sixth day symptoms of Jacksonian epilepsy were observed with signs of increasing pressure on the brain. A subdural hematoma was diagnosed and its evacuation restored conditions to normal.

39 Operations in Posterior Cranial Fossa—Krause gives an illustrated description of the technique with which he has successfully removed tumors in the cerebellar pontine angle, and reports a case in detail. The patient was a woman of 45. The tumor shelled out readily, and proved to be a fibrosarcoma measuring 18 by 25 mm. The symptoms of general pressure on the brain had developed gradually in the course of three years. The first symptoms were attacks of vertigo, gradually increasing to actual syncope, disturbances in hearing and tumbling toward the right side, with, later, intense headache, vomiting, diplopia and occasionally unconsciousness and convulsions. The left pupil was more dilated than the right and the corneal reflex on the side of the tumor was abolished. Pains were sometimes felt in the right side of the face. The right ear was entirely deaf. The patient could

hardly walk and turned constantly toward the right. If the eyes were closed the woman fell, and generally toward the right side. She had from three to ten attacks of vertigo a day, even when in bed. The mastoid process was not tender, the pulse was somewhat accelerated. The woman rapidly recovered after removal of the tumor, the choked disc subsided and the hearing and ocular reflexes were soon normal on both sides. She could walk without trouble or dizziness, and even with the eyes closed there were only slight traces of the former disturbances. In a second, similar case, a sarcoma, as large as a hen's egg, was found at the base of the brain, and the attempt to remove it was abandoned. The Gasserian ganglion was transformed into a tumor mass, and yet the patient had never suffered from trigeminal neuralgia. In some other cases internal hydrocephalus induced symptoms suggesting cerebellar tumor, and Krause exposed the left hemisphere of the cerebellum on one side and, three weeks later, the other hemisphere, but found nothing, although he made an incision in each so that he could inspect the arbor vitae to a depth of 3 cm. One patient derived great benefit from the relief from pressure after the operation, the choked disc subsided on each side, and she survived for three years. Autopsy revealed internal hydrocephalus. He describes some other cases in which autopsy confirmed the diagnosis of an extramedullary tumor near the atlas, and showed that it could have been easily removed if the surgeons had had a little more courage. He adds that the amount of compression which the spinal cord will bear is amazing.

41 Perforation of Ulcer of Stomach.—Körte relates his experiences with 19 cases of operative intervention for perforation of a gastric ulcer, with the recovery of 13 of the patients. All but five of the patients were men. The rigid abdominal walls were the most characteristic sign of the perforation, next came extreme sensitiveness to pressure at the epigastrium, at the umbilicus or over the entire abdomen. The contact of the acid gastric juice with the serosa ordinarily induces intense pain, but vomiting was noticed in only six of the cases and soon subsided. The physician must not be misled by this to assume that the trouble is transient. In two instances appendicitis was supposed to be responsible for the symptoms and the incision was made in the ileocecal region. An important sign for differentiating perforation in the stomach is the acid, sour smell of the effusion, while the effusion in case of appendiceal peritonitis soon becomes ichorous. One of the patients had been operated on twice, with a gastroenterostomy for callous ulcer of the pylorus, when the signs of perforation developed a year after the last operation. Four other patients were moribund when received. In three other cases an exploratory laparotomy was made on suspicion of perforation. In one case the trouble was traced to morphin addiction, in another no lesion was found in the abdomen and the patient died, presumably from perforation of an ulcer in the esophagus. In the third case nothing abnormal was found to explain the severe gastric symptoms occurring after a fall, and the patient soon recovered.

Brentano reviews 75 cases of perforation of gastric ulcer observed at the Urban Hospital, including 46 women, with 39 deaths, and 29 men, with 18 deaths. In 15 cases there had been nothing in the history to suggest a stomach lesion.

42 Peritonitis in Little Girls as Sequence to Acute Salpingitis.—Riedel has had occasion to observe eight cases of peritonitis in girls between $4\frac{1}{2}$ and 9 years old, secondary to acute salpingitis. He operated in every case on the diagnosis of appendicitis but was unable to save the patients. Another case was observed, but no attempt at operation was made. The same findings were encountered also in two young women. The infection was due to staphylococci or streptococci which had entered from the vagina and passed into the peritoneum through the tubes. All the patients had intact hymens. Another little girl had appendicitis first and then salpingitis. This brings to 17 per cent the number of cases of peritonitis from infection by way of the vagina in a total of 48 cases of peritonitis in girls under 10 at the Jena Hospital.

44 Lesions at the Splenic Flexure of Colon.—Madelung concludes this exhaustive study of the pathologic anatomy and

surgery of this part of the intestine with the statement that cancer of the splenic flexure offers more favorable conditions for a cure, even in advanced stages than cancer at other points in the large intestine. A palpable tumor can not be counted on. Study of the literature shows that glandular involvement is extremely rare. In six cases a complete cure for a period of from three to eight years to date is known.

45 Kidney Surgery.—Cebele reviews 50 operations on the kidneys done in von Angerer's service at Munich. His experience with cystoscopy of the blood has always been favorable and chromocystoscopy has also rendered him good service, but catheterization of the ureters is his main reliance. Seven of the 50 patients died, but in no case was the death due to insufficiency of the remaining kidney. There was a history of gonorrhea in a large proportion of the cases.

46 Tuberculosis of Kidneys and Bladder.—Kümmell warns that in tuberculous cystitis or nephritis the trouble is frequently referred to the genital organs, and the patients are treated for displacement of the uterus or for some allied condition, the physician not taking the trouble to examine the urine which would give the clue to the trouble. A chronic gonorrheal infection in a man or woman frequently causes an existing tuberculous affection of the bladder or kidney to be overlooked. Slight cloudiness of the urine, apparently slight cystitic disturbances, especially in women, slight pain in the kidney region and disturbance in the general health pallor and some loss in weight should compel examination of the urine for tubercle bacilli. Catheterization of the ureters confirms the diagnosis.

47 Cancer of the Tongue.—This volume of the *Archiv* was dedicated to the late E. von Bergmann on his seventieth birthday, and is illustrated by numerous plates. In this article on cancer of the tongue, Küster refers to von Bergmann's pioneer work in this line, and then describes a case in which great improvement followed the simultaneous application of Roentgen exposures and ligation of the external carotid on both sides. The patient was a man of 36, a cigar maker, and the growth was inoperable when first seen but under the treatment mentioned conditions improved to such an extent that the radical removal of the cancer became possible. The same measures applied in a second case were temporarily successful but collateral circulation soon annulled the effect of the ligatures and the patient succumbed to the progress of the cancer. Küster states that he has ligated the external carotid on both sides 33 times and has found 130 cases in the literature. The mortality has been about 1.54 per cent. His experiences were always favorable, even in his latest case, in which the artery was ligated on account of an aneurysm of the scalp in an infant of six weeks. His experience with cancer of the tongue indicates that the operations on the bones should be restricted to the minimum as they are more serious than surgical measures on the soft parts. Ligation of the external carotid he adds is no more dangerous than ligation of the lingual artery, while it is far more effectual.

51 Experimental Spinal Anesthesia.—Among the conclusions of the research reported is one to the effect that subdural application of an anesthetic does not cause intoxication unless the drug comes in direct contact with the centers of the medulla oblongata and of the brain. Absorption from the dural sac of the small amounts of anesthetics used in spinal anesthesia has no toxic action.

52 Treatment of Effusion into a Joint.—Hildebrand explains the effusion as the result of abnormal nervous excitability on the part of the synovial membrane and states that treatment should aim to reduce this excitability. Injection of carbolic acid or tincture of iodine answers this purpose but the effect can be much enhanced by preceding the injection of carbolic acid with an injection of salt solution to wash away the mucous secretions from the surface of the membrane thus allowing the carbolic acid to penetrate better into the tissue. The effect is also enhanced by completely expelling the fluid from the part. This reduces the amount of fluid that they take up the injection better, less resistance to the penetration of the fluid, and the protecting influence of

61 Induced Thrombosis in Treatment of Varices.—Tavel noticed that patients with varices who suffered from thrombosis, after operations on the enlarged veins, fared better later than those patients who had displayed no tendency to thrombosis. Acting on this suggestion, he intentionally induces thrombosis in such cases, and has found the results invariably superior. His first communication on the subject was summarized in THE JOURNAL, Feb. 18, 1905, page 590. His experience now includes 27 cases, all with gratifying outcome. The main trunk of the vein may be ligated by passing a curved needle around the vein and bringing it out through the hole in which it entered, thus encircling the vein with a loop which is then tied fast, the ends of the thread are cut off near the knot. The skin is then taken up in a fold, when the knot slips down out of sight under the skin. His more usual technic, however, is by a transcutaneous method which allows resection of a part of the vein, generally about 4 cm. In order to locate the vein, he outlines its course with fuchsin as the patient stands. In case the vein is not visible or palpable he draws a line from the inner condyle to the middle of Poupart's ligament. This corresponds approximately to the course of the long saphenous vein, although in the middle of the thigh the vein is sometimes a little farther toward the back. Twenty-four or forty-eight hours after the ligation he commences to induce thrombosis. This he accomplishes by injecting 10 cc. of a 5 per cent solution of carbolic acid. This irritates the intima of the vessel and induces an obliteratory thrombosis which spreads upward to the ligated point. A few days later, or at intervals of two or three days, another injection is made at another point until the entire varicose region is completely thrombosed, and the walls of the vessel become transformed finally, more or less, into connective tissue. The patient stands on a chair in front of a table and the syringe is introduced into the vein until the blood flows, then the syringe is filled with the carbolic acid solution and the patient sits down on the table and the solution is injected at two or three points. After this the patient is placed in bed or allowed to leave the clinic on foot, according to the conditions. There is occasionally a slight rise in temperature, but no disturbance has ever been noted in the general health. Usually the new circulation is soon established, but sometimes two or three months may elapse before normal conditions are restored. To promote the circulation he sometimes applies bandages or superheated air to the part and gives hamamelis and caffeine internally, especially in case of diffuse phlebectasia. The ligation must invariably be applied well above the points where thrombosis is suspected or anticipated.

The ligation above the focus of phlebitis and the induced thrombosis shorten the time of confinement to bed, he states, exclude all danger of embolism, and effect a radical cure of the phlebitis which otherwise is liable to recur.

62 Treatment of Isolated Subcutaneous Injury of Pancreas.—Karewski remarks that persisting hemorrhage and escape of pancreatic juice after injury of the pancreas are both threatening, but the latter is the more serious of the two and should be apprehended when the injury is near the head of the pancreas. He describes a case in which the laparotomy followed the injury in three hours, in Garré's case five and one-half hours elapsed before either hemorrhage or fat necrosis had had time to assume alarming proportions. Two other patients were saved by a prompt laparotomy and 12 succumbed when the operation was delayed. To promote the healing of the fistula after operation, it is important to restrict the production of the pancreatic secretion and to ward off metabolic disturbances from the loss of the juice. Meat and fat proved the most useful in this respect, in his case, while carbohydrates of all kinds had to be avoided. Large doses of sodium bicarbonate during and between the meals also checked the production of the juice. The healing of the fistula was promoted by application of tincture of iodine, with antiseptics to the skin outside to prevent maceration. The rapid healing of the pancreatic fistula in this case and the complete recovery of the lad after the severe injury to the pancreas render the case noteworthy as suggestive for future injuries of the kind.

65 Primary and Secondary Tuberculosis in Man.—Edens reports some new cases of intestinal tuberculosis—a total of 30. Infection in infancy, he thinks, is very common, but the individual organism reacts to it in some persons with the production of immunity, while in others the reaction takes the form of the "scrofulous diathesis," which entails greater susceptibility to secondary infection later.

67 Magnet Operation in Ophthalmology.—Hirschberg has applied the magnet in 347 cases of injury of the eye during the 27 years since he first suggested its application in ophthalmology. In 36 out of 64 cases between 1896-1903, an iron splinter in the retina or vitreous body was successfully removed with the magnet, leaving little if any impairment of vision. In 22 cases the splinter was so large or inflammation had already set in, so that finally the eye had to be enucleated. In 2 recent cases the magnet operation was performed on the injured eye when the other eye had long been blind. In one of these, an iron splinter, 2x2 mm., weighing 5 mg., was removed from the anterior chamber with the large and hand magnets nearly two years after the injury, with successful outcome.

69 Registration of Auricle Beat Through the Esophagus.—Joachim describes a case of "dissociation of the auricle and ventricle rhythms." The presumptive diagnosis from the extreme slowness of the pulse and the syncope spells was confirmed by registration of the auricle beat by way of the esophagus, according to the technic described by Minkowski and Rautenberg (THE JOURNAL, Sept. 22, 1900, page 975). Joachim reproduces the tracings, but adds that the procedure is extremely tedious and disagreeable for the patient, even to the point of affecting the general health for several days afterward.

70 Quantitative Test for Sugar.—Bang makes high claims for the convenience, extreme precision and rapidity of the simple test for sugar in the urine which he here describes. The presence or absence of albumin does not affect the findings, and they are more accurate in the presence of very small amounts of sugar than with any other test, polarization, fermentation or reduction. Instead of a caustic alkali he uses potassium carbonate in the solution of copper, and titrates with hydroxylamine until the blue tint vanishes. The first copper solution is made by dissolving with heat 500 gm. anhydrous potassium carbonate, 400 gm. potassium sulphocyanate, and 100 gm. potassium bicarbonate in 1,200 cc. water. When the mixture has cooled, a solution of 25 gm. crystallized copper sulphate in 150 cc. water is added, the vessel rinsed, and the jar filled up to the 2 liter mark. In another vessel,

0.55 gm hydroxylamin sulphate, and 200 gm potassium sulphocyanate are mixed with water to the 2 liter mark. Both solutions are durable, and 1 c.c. of the hydroxylamin solution will decolor 1 c.c. of the copper solution. To 10 c.c. of urine 50 c.c. of the copper solution are added and the whole boiled for three minutes. The vessel is then rapidly cooled under running water, and the fluid is then titrated with the hydroxylamin solution until the blue tint vanishes, which is usually in a few seconds. He gives a little table showing that 44 c.c. of the hydroxylamin solution correspond to 4.9 mg sugar, 33 c.c. to 15.4 mg sugar, 22 c.c. to 27.7 mg sugar, 11 c.c. to 41.8 mg sugar, and 1 c.c. to 59.4 mg, and so on. He is now experimenting to establish beyond question the standards for normal urine, for comparison.

71 Granules in Leucocytes.—Mühlmann reports that he has seen active movements in the granules in living leucocytes. He also states that the ultramicroscope has shown that Müller's "hemocoma" or blood dust consists in reality of particles of fat in the blood.

78 Quinin Amaurosis.—Seeligsohn's patient was an anemic young woman who took 6 gm (90 grains) of quinin in the course of three days. Vertigo, tremor and absolute deafness and blindness followed. Hearing returned in a day or so, but the blindness persisted for ten days and normal vision was not regained for two months.

81 Isolated Colitis and Sigmoiditis.—Rosenheim has had occasion to observe a large number of cases of a localized acute or chronic inflammatory process in the colon or at the sigmoid flexure. The sigmoid process is generally chronic with occasional acute exacerbations, and the usual symptoms are disturbances in defecation and pains, tenderness of the part affected and thickening of the wall of the intestine to actual tumor formation. The extension of the infiltration over considerable stretches of the intestines speaks against the malignant nature of the process, as also normally shaped stools, showing the absence of stenosis. He describes 5 typical cases to show the various manifestations of the affection. One patient was a man of 63, somewhat "nervous" with arterio-sclerosis who noted a progressive tendency to obstipation, with blood and mucus in the stools, at last, dyspepsia and loss of weight. Gradually the abdominal pains increased in intensity, with, finally, a severe attack of colic, which recurred after three months. The sigmoid flexure rapidly swelled and signs of peritonitis were observed with transient fever, muscular rigidity on the left side and fetid stools with pus. The acute symptoms then promptly subsided, and in the course of a few months the whole process in the sigmoid flexure gradually subsided and the intestinal functions returned to normal. The treatment was mainly dietetic: a bland mixed, vegetable diet free from residue, bed rest, hot poultices to the side, and daily injections of 100 gm warm oil. The lack of proportion between the clinical picture and the extent and softness of the tumor were the main points for differentiation of the condition from cancer. In a second case an otherwise robust man noted progressive obstipation and painfulness of the left side of the abdomen. The colon above and the rectum seemed to be normal, while the sigmoid region was evidently the seat of in-

filtrating inflammation. The wall of the intestine was thickened over a large expanse, as also in the third case related. In this case sigmoiditis accompanied by infiltration of the wall developed with a stormy, acute onset, with fever and great disturbances, subsiding into a chronic phase, manifested by constipation, blood and mucus in the stools and a palpable tumor. During convalescence a drastic purgative brought on an exacerbation, which subsided under treatment, with apparently complete restitution. The restoration of function and vanishing of the tumor confirmed the non-malignant character of the affection. Another differentiating point is the possibility of introducing the endoscope tube for a considerable distance—as far as 40 cm in one instance. In another case the sigmoiditis was mild, but with recurring disturbances, relieved by appropriate measures—brief cold sitz baths, with brisk rubbing afterward of the entire body until the extremities were warm and a bland vegetable diet. The sigmoid region now feels normal on palpation. Previous local and internal measures had proved ineffectual. In the fifth case reported a severe inflammatory process in the sigmoid flexure developed on the basis of an old persisting enteritis accompanied by recurring diarrhea.

82 Treatment of Tuberculous Hip Joint Disease.—This clinical lecture by Hoffa is illustrated and presents the present status of treatment in detail. Even at the best it is very long and tedious with exclusively conservative measures, but his extensive experience has conclusively demonstrated that the ultimate results are much better, functionally, than with operative measures. Prolonged supervision of patients has shown that much greater functional capacity is the rule in later life among those treated conservatively. Even after operation, it is usually necessary that a support should be worn for years to ensure good results. He warns against abrupt measures in treating the contractures and luxations left after the coxitis has apparently healed. They are too liable to fan the almost extinct focus into a flame again. The contracture must be very slowly and gradually corrected. He adds that the greatest progress that has been realized in the last decade is in the technique of dressings and supports.

83 Electric Accidents.—Jellinek has devoted many years of research and experiments to the subject of accidents from electricity. In regard to treatment he advises systematic artificial respiration with stimulants for the heart, massage, faradization of the heart and neck regions, venesection, injection of camphor, adrenalin, etc. Lumbar puncture is also indicated, as he relates in detail and is entirely harmless. In the cases in which no results are observed after hours of artificial respiration, it might be advisable, he says, to turn on the current again through the body. The flat, positive electrode is placed over the heart region, the rod-shaped negative electrode, wrapped in cotton impregnated with salt solution being placed in the rectum. The current is then turned on and off, instantaneously several times. The heart and vessels in the neck are examined after each application. He has previously reported experiments on animals which showed that it is sometimes possible to start a heart to beating by means of the same current which had previously arrested the heart action. Of course this heroic measure is indicated only in cases otherwise given up for lost, but future research may justify its application earlier. The patient during all the maneuvers should lie with the head somewhat raised to prevent escape of blood from injured vessels. If the artificial respiration is not done according to the rules of the art it may produce conditions which doom a patient who might otherwise have been saved. An instance of this kind is related. The accident occurred soon after breakfast and artificial respiration, venesection, lumbar puncture, etc. had all been applied. Autopsy next day revealed that the upper air passages and also a part of the lungs were clogged with st. mucus, and that the right ventricle was full of air. The latter was undoubtedly due to suction of air through the opening into the vein when the artificial respiration was resumed after venesection. Jellinek warns that the artificial respiration must be continued during venesection and not discontinued. The vein has been compressed above. Artificial respi-

for many hours. The only limit to the time devoted to artificial respiration is the appearance of unmistakable signs of actual death. Many a life might have been saved, he adds, if artificial respiration had been kept up longer. Much and perhaps everything depends on how soon after the accident artificial respiration is commenced. Expectant, symptomatic treatment with strict supervision should be the rule after resuscitation, especially on account of the possibility of sudden development of mental disturbances. Prolonged warm baths with cold applications to the head have been found useful, with bromids in case of agitation. The tendency to retention of urine and feces and to chilliness should be combated, and the skin lesions should be treated conservatively. They may be several months in healing.

86 Intravenous Administration of Strophanthin.—Starck announces that intravenous injection of strophanthin allows the drug to act almost exclusively on the heart, while the dosage can be mathematically exact, and the effect on the heart is always amazingly prompt and powerful. Tests with it on animals and in the clinic have shown that this technic far surpasses all other methods in its rapid and energetic tonic action on the heart. He gives the details in 7 cases in which it was used. No by effects were ever noted, although as much as 2.25 mg was injected in one case in the course of three days. The average dose was 1 mg, never more than 1.25 mg, at a time. The pulse changes almost at once after the injection, approximating normal characteristics, as also the heart and lung action. One patient was in such an advanced stage of pulmonary edema that the strophanthin was injected as the last resort for an apparently moribund patient, but the injection of 1 mg of strophanthin induced prompt relief, freeing the lungs and raising the output of urine from 700 to 3,000 cc in twelve hours. In another case the urine increased from 300 to 3,000 cc in twelve hours. The results were better in the chronic cases. He affirms that his experiences seem to indicate that strophanthin is less toxic than has been hitherto supposed.

92. Relation of Acromegaly and Tumors of the Hypophysis

—Cagnetto writes from Padua to report 5 cases of acromegaly with concomitant tumors in the hypophysis. He also reviews the recent literature on the subject of the connection between the disease and the tumor. The evidence thus accumulated testifies against the assumption that acromegaly is due to excessive functioning of the hypophysis. Cases of acromegaly are known in which there is no hyperplasia of the glandular lobe of the hypophysis as also cases in which the gland has actually no functioning elements. Tumors of the hypophysis have been encountered which contained abundance of functioning cells, and yet no acromegaly was observed.

96 Morphology of Cells in Gonorrheal Secretions—

Neuberger's extensive study of the morphology of lymphocytes, mononuclear leucocytes, etc., in the urethral secretion in numerous cases of gonorrhea demonstrated among other findings that the mononuclear leucocytes were exceptionally active as phagocytes under these conditions, incorporating especially the multinuclear leucocytes which assumed a spherical shape. Gonococci were frequently found in them also.

97 Differentiation of Pneumococcus and Streptococcus—

Tests with sodium taurocholate proved the most reliable in Levy's differentiating research on these micro-organisms. Blood agar and the other media gave contradictory results. He announces that the variety known as *Streptococcus mucosus* is in reality a pneumococcus, and should be designated *Pneumococcus var mucosus*.

98 Gummatous Pleurisy—In Lissauer's case the numerous signs of constitutional syphilis observed at autopsy and the total absence of tubercle bacilli or tuberculous lesions, confirmed the gummatous nature of the nodular pleural affection.

108 Fatal Hemoptysis in Tuberculosis—Thue states that out of 795 phthisical patients in the public hospital, about one-third had hemoptysis, 447 died in the hospital, death being due to hemoptysis in 13 cases. In 7 of these patients no source for the hemorrhage could be detected. In 8 instances the fatal hemorrhage was the first hemoptysis that had occurred during the sickness.

109 Intentional Subconjunctival Fistula in Treatment of Glaucoma—Holth noticed that the cases of glaucoma in which the classical operative measures had been done with apparently defective technic—leaving a fistula—presented much better functional results later than those cases in which the operation had been done with such perfection that no fistula resulted. He reasoned that the subconjunctival fistula must contribute to this result, and now intentionally makes a fistula in operating for glaucoma. He here describes his technic in detail, with 25 illustrations, and announces that the results of its application in 40 cases have been most encouraging. Vollert's favorable experiences with 4 cases were mentioned recently in these columns.

111 Transmission of Infectious Disease by School Books—

Hanson gives the details of a small epidemic of an infectious disease among the pupils in a military school. He noticed that the infection occurred in bunches with certain intervals—corresponding to the return of the sick from the hospital. The last first infected had been spending a vacation at home where his sister had the disease. No other cases developed until from 3 to 6 days after his return from the hospital to his schoolroom. Then 10 lads became infected and were sent to the hospital, no further cases occurred until about a week after they had been dismissed from the hospital, when another bunch of 5 cases developed. Every precaution in regard to disinfection before dismissal from the hospital and disinfection of the sleeping rooms had been taken with extreme care, but the return of a group from the hospital was always followed by the development of new cases. After this had been noted four times it was found that the lads had taken their schoolbooks with them to the hospital and had used them there and brought them back, without submitting them for disinfection. As soon as this was stopped the epidemic was arrested at once.

OBSERVATIONS RELATING TO THE NATURE OF ATROPHY OF INTESTINAL ORIGIN

DAVID L. EDSALL, M.D.

Assistant Professor of Medicine, University of Pennsylvania Wood
ward Fellow in Clinical Chemistry William Pepper
Laboratory of Clinical Medicine.

PHILADELPHIA

General atrophy that is associated with, and apparently stands in direct relation to, a greater or lesser degree of preceding intestinal disturbances occupies a position of profound importance in the pathology of infancy. Marasmus is, indeed, so common and often so intractable that the laity are almost as familiar with its general features as are physicians. Much less commonly, but still occasionally, a condition that is, in its chief clinical features, apparently the same as the atrophy of infancy, appears in early childhood. In later life, typical cases of this kind are rare, there are, however, very many instances of serious disturbance of general nutrition that seem to bear a direct relation to intestinal trouble, but are too pronounced in their general features to be satisfactorily explained by the mere loss of nutriment that occurs through lack of digestion and absorption—for these patients may still be absorbing an amount sufficient to maintain or improve nutrition, and yet they emaciate or remain about stationary in a condition of more or less profoundly depraved general nutrition. Cases of this kind have recently been studied by Roehl, who decides that the disturbance of nitrogen absorption does not suffice to explain the tissue loss, and the general absorption is at times quite sufficient to cover their needs.

THEORIES REGARDING ATHREPSIA

An immense amount of work has been devoted to the study of the pathogenesis of infantile atrophy, particularly, but no satisfactory explanation of the nature of the condition has been furnished. It has been shown that digestion and absorption are impaired in most or all atrophic infants but the degree of impairment is often by no means enough to explain the atrophy. I have myself with Dr. Caspar Miller studied the absorption in several such cases, and while it was below normal, it was not exceedingly bad and the infants still absorbed an amount sufficient to have made most of their contemporaries gain in weight and health.

The lesions found at autopsy are, too, insufficient to explain the condition. There is still a somewhat general belief that an extensive primary atrophy of the intestine occurs in these cases but while this has repeatedly been described and has been considered the cause of the general emaciation it has been shown by Heubner, Gerlach and Habel that the appearances on which so much stress has been laid are really due to the

manner in which the intestinal wall is prepared and cut for microscopic examination. Wentworth's recent able review of the pathology of the condition leaves only a single fact undisproved—Bloch found in several cases an absence of the granules that are normally present in Paneth's cells.

The hypothesis has also been put forward (Escherich) that the disorder may depend on the ferments and other obscure biologic elements in human and animal milk. This, however, could not explain the matter, for it leaves out of consideration the fact that athrepsia occurs in only a portion of artificially fed infants and not in all.

Recently a suggestion of another kind regarding the nature of the condition has been put forward. Since the injection of animals with protein of foreign species is followed by the development, in the blood serum of the animal injected, of substances capable of precipitating the protein that was introduced, Moro and Hamburger have attempted to show that the serum of atrophic infants contains a precipitin for cows' milk—thinking that they could in this manner demonstrate that foreign protein (namely, bovine casein) reaches the circulation in such cases. If this were the case, it might be conceived that this foreign protein produces chronic toxic symptoms that lead to emaciation, even though sufficient food be absorbed. They were not successful in their work, but Moro has recently found such a precipitin in one case. He declines, however, to draw any conclusions from this as to the nature of infantile atrophy. Even if such a precipitin is frequently to be found its presence may, I think, be quite as properly, if not more properly applied in another way, in support of my own working hypothesis regarding the nature of infantile atrophy, which hypothesis I shall describe.

RECENT VIEWS OF PROTEIN DIGESTION

I shall first, however, in order to make the character of my conception clear find it necessary to refer very briefly to some of the recent transformations of view concerning the nature of protein and the manner in which it is digested and utilized by the tissues and shall refer also to some points in regard to ferments. All the matters are well known to those that have had particular interest in such questions but are not yet generally appreciated.

The comparatively simple teaching of a few years ago when put into its briefest form was that the digestion of protein consists essentially of hydrolysis into albumoses and peptones and the formation of small amounts of some simpler bodies—chiefly amino acids such as leucine and tyrosine and that the albumoses and peptones are absorbed and in the process of absorption or very soon after thus built up again to protein. The process as conceived at that time was that the main part merely hydrolyzed and the small amount of protein—the main part merely hydrolyzed—

remaining protein all the time, and the chief apparent purpose of digestion being to transform the ingested protein into substances that are relatively very soluble and that easily pass animal membranes, that is, to get them into a form in which they can readily reach the circulation

Throughout recent years, however, it has become increasingly evident that the change is much more fundamental than this, and the key to the understanding of the main purpose of digestion seems to have been furnished by more elaborate study of the products of digestion, and particularly by a more intimate knowledge of the composition of protein. That is, it has been shown that a protein consists of a union of numerous crystalline substances which are relatively simple in their structure as compared with protein, but still somewhat complex, these are chiefly or entirely so-called amino-acids, among the many of which leucin and tyrosin are the most popularly known representatives. Protein substances of different kinds contain varying amounts of the various amino-acids, but they differ quite as much in the quantity as in the quality of the component substances. Some forms of protein do contain some kinds of amino-acids that other protein substances do not, but the distinction between different protein substances seems to lie quite as much, if not more, in the fact that thus one contains more of certain amino-acids, that one contains less of these amino-acids but more of others. To use the picturesque simile employed by the Germans to describe the matter, proteins are constructed of "building stones," and stones of many shapes are used in building any protein, but the ultimate structures differ in their architecture, and in giving them their proper form, sometimes more stones of one shape are employed, sometimes more of another.

Concurrently with the development of the above mentioned knowledge, it has been shown that the digestive breakdown of protein is much more complete than was previously taught. Even pepsin can carry a large part beyond the peptone stage, and trypsin does this much more quickly and extensively than pepsin. Trypsin, indeed, is capable, even in laboratory experiments, in some circumstances, of carrying the whole amount of protein beyond the peptone stage, and, hence, under the more favorable conditions that exist in the animal organism, it probably carries most, possibly nearly all, beyond that stage.

At the same time, it has been made apparent that the intestinal mucous membrane contains a proteolytic ferment which has been given the name erepsin. Whether this has the characteristics attributed to it by Cohnheim—namely, inability to attack native protein, but active powers of further fragmenting albumoses and peptones—or whether, like trypsin, it can carry on the process from the beginning, is a question that is still *sub judice*. Of the existence of a proteolytic ferment in the intestinal mucous membrane, there is, however, no question, and there is every probability that it is produced there and is not simply pancreatic trypsin that has lodged there.

It seems at present that the purpose of digestion is to fragment the protein complex thoroughly into its constituent amino-acids or building stones, and that the protein falls first into the hands of pepsin, then trypsin, and next the ferment of the intestinal mucous membrane in order that with each attack the fragmentation may be made more complete. It is not yet clearly determined whether these ferments actually differ as they

have been supposed to do, in the nature of the end products that they produce. The progressive action of one after the other may be intended simply to permit each succeeding ferment to put finishing touches on the portions of unfragmented or partially fragmented protein that have escaped the preceding ferments. The prime object of this breaking-up process appears to be to yield the amino-acids themselves, in order that they may be available in free form and in proper quantities, for a complete reconstruction, which will yield protein homologous with the individual to be nourished. It is not necessary to fragment all portions completely as certain fractions will be obtained that can be reconstructed into homologous forms without complete fragmentation, but except for such fractions it must be complete. That the digestive process, together with the subsequent reconstruction process, does accomplish this transformation—that is, that it does change protein of foreign species, containing certain amino-acids in quantities peculiar to this protein, into another form of protein, apparently containing the same amino-acids in quantities peculiar to the individual that has digested and absorbed the protein—has been shown experimentally with almost final positiveness, and it has likewise been shown that the reconstructive process occurs before the absorbed digestive products reach the general circulation, almost certainly, indeed, in the intestinal wall itself.

Furthermore, physical chemists consider it to be theoretically well nigh certain that the same ferment that accomplishes fragmentation also causes the reconstruction—that the direction in which a ferment acts, whether toward the production of simpler products or toward the formation of more complex substances is determined, not by the nature of the ferment, but by the physical and chemical conditions of the medium in which it acts and by the concentration of the products of digestion. If conditions favorable to disintegration are present, the ferment hastens this, but if the conditions favor synthesis, the same ferment hastens this. This has actually been shown to occur with some ferments that act on carbohydrates and fats, and similar observations that are suggestive, though not yet conclusive, have been made regarding proteolytic ferments, the conditions of such experimentation with the latter ferments being much more difficult than those attached to carbohydrate and fat ferments. If this view that ferments are capable of reversed action is correct, as a general principle, and this now appears most probable, the same ferment in the intestinal wall that continues the process of fragmentation of the protein food also carries on the process of reconstruction of homologous protein.

This cursory statement of some of the main aspects of the present day teaching of the physiology of digestion will, I trust, suffice to make clear the hypothesis that led to the observations I am about to report. My results have not yet been sufficiently extensive or elaborate to justify of themselves, quite so formidable a preamble as I have given, were it not that the explanation is necessary in order to make their bearing clear. So far as they go, however, they offer some support to the following hypothesis.

THE AUTHOR'S HYPOTHESIS

Clinically, it is quite clear that most atrophic infants do well provided they are not already far advanced toward death if human milk can be given them, while with even the most capably conducted artificial feeding,

they usually have, at best, a precarious and long struggle for existence, and very often go slowly, but persistently, toward death. It seems, then, that the difficulty consists in making use of milk of foreign species. The difficulty does not lie simply in accomplishing the absorption of the elements of the heterologous milk, for, as I have already noted, sufficient is absorbed in many of these instances to produce a gain in other infants.

It has seemed to me that the disturbance may be the result of disorder of the ferment function of the intestine. That is, when the protein of the food is progressing in the course of its breakdown the final attack by the ferment of the intestine does not occur or is ineffectual, that the protein complex is torn apart more or less completely by the pepsin and trypsin, but that fragmentation sufficiently complete, in order that the structure may be rebuilt in a new form entirely homologous with the patient's tissues, does not take place.

Granting the absence or serious reduction of this ferment in cases of atrophy, one of two things may be conceived of as occurring as a consequence. In the first place, it might be that the protein would be fragmented to various stages short of absolute completeness—to albumoses, peptone, simpler non-protein amino acid complexes (heptides) and in more or less considerable extent, to free amino-acids—and that these would then be reconstructed, but the synthesis taking place without sufficient preceding fragmentation, the product of synthesis is not the normal one, but is more or less hybrid in character. To use again, for clearness of conception, the building stones simile, it would be like taking away the upper structure of a building, while leaving the foundation unaltered, and then making the new structure conform to the old foundation, instead of tearing out the latter completely and building anew from the start. The infant would, in such a case, have his circulation and tissues supplied with more or less markedly foreign protein, while normal infants receive homologous protein. The infant nourished with mother's milk, even though he absorbs all his protein food wholly unfragmented or only half fragmented, would not so far as we know, be crippled by this, for his food protein is already homologous. The artificially fed infant that I have postulated, however, who receives imperfectly broken down, and hence improperly reconstructed protein, has manifest difficulties in his way in carrying out metabolic processes, and the most evident difficulty would be in tissue construction. He would be able to use much, at least, of the more or less completely foreign protein in obtaining energy, that is, he would be able to disintegrate it, for it is known that animals can thus utilize considerable amounts of foreign protein when introduced subcutaneously or into the circulation. In attempting to use it to construct tissue, however, he would be obliged to go through the difficult task of disintegrating again, and then completely reconstructing it, while when the tissues are as is normally the case, served with homologous protein, it would seem evident that the process of construction and repair of the tissues would be comparatively easy. We have, indeed, no knowledge that the tissues are capable of building new tissue from foreign or partly foreign protein served thus directly to them, and it may readily be that they are more or less completely incapable of it. They can undoubtedly secure energy from it and can transform one variety of homologous protein into another variety of homologous protein but this is very different from transforming a foreign protein into a homologous

protein. Even if they could do the latter, to impose on them the necessity for carrying it out would be to make entirely unnatural demands of them, and they would doubtless be likely often to fall under the extra burden.

The second idea conceivable as the result of absence of the intestinal proteolytic ferment is dependent on complete acceptance of the theory of reversibility of ferment action. While this theory now appears to be probably susceptible of general application, this has not been actually demonstrated to the same extent as have the other matters that I have so far used in constructing my hypothesis. Therefore, although this theory will probably be shown to be correct, I mention its relation to the subject under discussion in only a secondary place. In case it applies in this instance the effect would appear to be that, the intestinal ferment being reduced or absent, not only would disintegration of the protein suffer, but the especial agent that carries out the reconstruction of protein being decreased or absent the reconstruction also would be more or less completely absent. Instead, therefore, of entering the circulation as hybrid reconstruction products, the more or less completely fragmented products would themselves go into the circulation, and use of them by the tissues, in the synthesis of new tissue, would be much the same difficult process as in case they had been made into hybrid protein.

Either of these ideas would be in harmony with the repeatedly mentioned fact that absorption in many of these cases is sufficiently good to maintain nutrition, for incomplete fragmentation would not prevent absorption, since digestion products, all the way from albumoses on, are readily capable of absorption—and indeed, this occurs with many unchanged albumins. The hypothesis is would in either case also, be in harmony with—indeed, it is dependent on and, if correct explanatory of—the fact that the difficulty lies in the utilization of milk of foreign species. There is no good evidence that infants ever fail to assimilate human milk, unless they are already desperately ill, provided that the milk is not so rich in some of its constituents as to upset digestion or so poor as to be insufficient, and provided, also, that the mother or nurse supplying the milk is not the subject of physical or emotional disturbances that presumably cause the quality of the milk to be disordered. In other words, there is no evidence that an infant, not desperately ill, that is taking normal human milk of such composition that it does not disturb digestion, ever fails to be able to utilize this milk on account of the character of its constituents. On the other hand, large numbers of infants, when fed on foreign (that is, usually cows') milk even when the constituents are of wholly normal quality do badly or die, however one may vary the proportion of the constituents in deference to difficulties in digestion often indeed even when no noteworthy difficulties in digestion are present. The experience of Westcott Holt and others shows that many malnourished or even severely atrophic infants that do badly on cows' milk mixtures exhibit remarkable improvement if, while their diet still consists chiefly of the same mixture small quantities of human milk are added. This suggests strongly that they can secure from the artificial food the energy that they need if only the essential moiety absolutely demanded for tissue building and repair is given them in normal form.

The hypothesis also confirms the fact that infantile atrophy as well as atrophy in children and adults. There is no definite

phic cases, all those that show slight ferment-action provide, to indicate this, figures so small as to be almost or quite within the range of error. Since, however, in all instances, two nitrogen-estimations were, as is usual, made for the purpose of controlling the results, and since, in all instances (except case 5, in which the control was lost), the two estimations corresponded practically exactly, I think that the figures are accurate, and do not indicate slight ferment-action.

The figures from the three control cases that had not simple atrophy do not, to be sure, indicate the digestion of large absolute amounts of protein, but they do show relatively large amounts as compared with the atrophic cases, and it must be remembered that I was dealing with small figures in all cases, since, as may be seen in the protocols of the experiments, only 10 c c of milk was introduced in each instance for the ferment to act upon, in addition to the small amount of protein present in the extract which contained the ferment, and the amount of milk mentioned represents only about 0.05 grams of nitrogen. Considering that the period of digestion was purposely made short (only four hours), in order to be more certain of excluding bacterial action, the figures in the non-atrophic cases really show a very considerable degree of digestion, while the atrophic cases, at best, show almost none.

The objection may be offered that the differences were due to bacterial action. Toluol was used freely, however, the experiments were made so short that there was little opportunity for bacteria to act, and, more important than this, there are no irregularities in the results to suggest that bacteria had been active. It is, perhaps, impossible in experiments carried out as these were with an extract of the mucous membrane, to exclude bacterial action absolutely. I used this method, however, instead of attempting to isolate the ferment by means of precipitation and dialysis, because I believe that it is possible only by means of the method followed to secure quantitative comparisons in different cases, and bacterial action cannot be said to have produced the results obtained, unless one assumes the rather strained position of considering that bacterial proteolysis occurred regularly in the non-atrophic cases, while it was regularly absent or almost absent in the atrophic.

Leaving aside the two cases in older persons for the present, the bearing of the results in the three of infantile atrophy seems to me to be the following. So far as these cases go, they harmonize with the hypothesis that I have stated, since they demonstrate that in these cases there was great reduction or entire loss of proteolytic power in the intestinal mucous membrane. It may readily be thought that this was a mere secondary effect of the profound emaciation, but this appears decidedly improbable, when one considers the three control cases, all of which were extremely emaciated, but as the result of definite causes other than simple atrophy. These cases show very much greater proteolytic action than do the atrophic cases. It might be considered, also, that there was simply a general reduction in the ferments of the digestive tract. I attempted to exclude this objection by testing for pepsin in extracts of the gastric mucous membrane of the atrophic cases, and in all three instances I got a markedly positive result, hence pepsin was present in all.

Beyond what I have said I do not think I can speak decidedly as to the meaning of my results. If continued studies shall show similar results consistently, this will demonstrate definitely a marked disturbance of the fer-

ment-function of the intestine, and will indicate strongly that this has an important primary relation to the atrophy. Further studies are necessary, however, in order to show that this is a constant condition in atrophy, and a condition that is usually absent in other cases. Furthermore, in addition to the line of observation that I have been following, it is important to determine whether the intestine does or does not, in these cases, retain its power to produce secretin and enterokinase, and thereby to excite secretory activity in the pancreas and to activate the pancreatic trypsin. It is likewise important to determine, if possible, to what extent the pancreas retains its functional capacity in these cases, although this is extremely difficult to do satisfactorily with postmortem material, because in extracts of the pancreas the trypsin becomes, to some extent, activated, and it is difficult to determine to what extent this occurs, and therefore difficult to secure reliable results in comparing different cases.

In spite of the fact, which I have repeatedly mentioned, that absorption in these cases often does not suffer enough to explain the atrophy, it may be that the pancreas, as well as the intestine, shows reduction, and perhaps, entire loss of ferment-function. We know now quite clearly that fat-absorption is sometimes good in the entire absence of pancreatic secretion, and it is quite possible that this is more largely true of protein than we have thought. Indeed, in many cases, with severe lesions of the pancreas, the nitrogen-absorption is known to be not bad. This possibility of disordered pancreatic function is of particular interest in infants, for there is some testimony, though not based on very good evidence, that in the first three months or so of life the pancreas has only a subordinate rôle in carrying on digestion and absorption, while after this it becomes increasingly important. Athrepsia in infants is particularly likely to begin about the third month of life, and, hence, if the above-mentioned view is correct, it becomes possible that the difficulty in athrepsia may be partly, at least, the result of failure of the pancreas to take up the large function that it should assume. If the pancreas fails to do its duty, fragmentation of the protein-molecule will be still more incomplete than if the intestinal ferment only were absent. In this case, pepsin alone would be left to digest the protein sufficiently for its absorption, but in infants, at any rate, with their simple milk diet, it is probable that pepsin is capable of doing at least a very large part of this. If there is any truth in the view that I have just noted concerning the development of the pancreatic function in early life pepsin must, in even normal infants, in the very early weeks of their existence, do most of the work except that carried out by erepsin.

In addition to what I have mentioned it is desirable to attempt to determine whether amino-acids or peptides do escape into the circulation in these cases, or whether, on the other hand, the circulating protein of atrophic cases shows differences from the circulating protein of other cases. These last points are very difficult to determine with our present methods, particularly with the paucity of material provided by the cadaver of an athreptic infant. They may be possible of solution in cases of atrophy that occur in older persons, perhaps even during life.

Furthermore it is desirable to determine whether there are alterations in the ferments in the tissues that lie beyond the digestive tract.

Finally, I would with an equal consideration of the

CONTROL CASES

CASE 6—Infant of nine months, dead of general tuberculo-
sis Crepsin digestion experiment

Unbolled	0 0306
Bolled	0 0112
Increase	0 0194

Witte peptone digestion Boiled pronounced buret, un-
bolled very slight

CASE 7—Infant of five and a half months, dead of slow star-
vation (Extremely insufficient feeding by an ignorant mother,
admitted moribund) Crepsin digestion experiment

Unbolled	0 0215
Bolled	0 0147
Increase	0 0068

Witte peptone digestion Boiled very distinctly more marked
than unbolled

CASE 8—Adult, died in convalescence from typhoid fever,
after a long illness and extreme emaciation Crepsin digestion
experiment

Unbolled	0 0220
Bolled	0 0117

Witte peptone digestion Boiled marked, unbolled slight

HEMOLYSIS IN PERNICIOUS ANEMIA, AUG- MENTED BY URINARY RETENTION

REPORT OF CASE

HUGO A. FREUND, A B, M.D.

First Assistant in Internal Medicine University of Michigan
ANN ARBOR, MICH

An article on "Recurrent Intermittent Retention of Urine Occurring with Remissions in a Case of Pernicious Anemia" attracted my attention and led me to compare it with a similar case lately observed in the medical clinic of Professor George Dock. Dr Cunningham's case was a male, aged 47, who had well-marked symptoms, physical features and a typical blood picture of pernicious anemia. In addition he had a history of retention of urine four years before, after which he was regularly catheterized for three months. At the time of his admission he urinated every two hours and was up more often during the night. In addition, difficulty in starting his urine and dribbling were complained of. Examination revealed a hypertrophied prostate, sufficient to cause frequent attacks of retention. Cystoscopic examination showed a chronic cystitis, and on draining the bladder as much as thirty-six ounces of residual urine were obtained. Bottini's operation was performed under cocaine anesthesia. In three months the patient had no urinary symptoms and his blood was in good condition. He returned because of the reappearance of the anemia one month later, and complained at the same time of urinary symptoms—namely, dribbling and difficult micturition. The residual urine had again increased. The bladder symptoms were relieved, and along with the improvement in his blood his urinary symptoms became better. In six months he had a similar attack and again recovered. Finally two years and two months after the onset another attack came on from which the patient never recovered, dying from "uremia." In these numerous attacks the lowest blood count was 472,000, hemoglobin 10 per cent., the highest 3,500,000, hemoglobin 45 per cent. The postmortem of the urinary system revealed chronic cystitis, hypertrophied prostate, dilatation of the ureters, kidneys, pelves and calices. Urinary

findings at each examination were practically the same. The urine was pale, of low specific gravity and acid or neutral. There was a trace of albumin, but no sugar. There was always sediment consisting of pus, blood, and hyaline and granular casts.

In many respects the case I purpose to report herein resembles the one just outlined.

Patient—M L, aged 56, stonemason, American and single, came into the medical clinic on Jan 4, 1907, complaining of numbness, stiffness of the hands and feet, diarrhea and loss of appetite.

History—There was nothing notable in the family history. He had had typhoid at 15. He denied venereal diseases. Drank beer in moderation and smoked six pipefuls of tobacco daily. Five years previously, following exposure to cold and dampness, both shoulders became stiff, and there was some loss of power in his legs. The weakness persisted and this he noticed was more apparent on the least exertion. Diarrhea began two weeks before coming to the clinic, with from four to six stools per day. At this time he had grown dizzy and stumbled occasionally. His hands were numb and he found it impossible to button his clothes. He had had difficulty with urination for some time, but could not definitely remember the time of onset. In the early part of October he began to find it necessary to get up at night to urinate. Soon after this a burning pain at the beginning of urination and dribbling annoyed him. These symptoms became more pronounced so that when seen the patient urinated about every two hours and found it necessary to rise at least three times every night to empty his bladder. The urine was small in amount, pale yellow, and slightly turbid.

Examination—Patient was of medium frame, skin dry, very pale, freckled and inelastic. There was a small amount of panniculus. The hair was scanty and gray. Height five feet eleven inches, weight 122 pounds. The pupils were equal and reacted to light and accommodation. The teeth were very poor, the gums were red and spongy, the tongue fissured, moist, glossy and tremulous. The mucous membranes were pale. The neck was symmetrical and the thorax of good length, breadth and depth. The clavicles were prominent. The apex of the right lung was lower than that of the left and there was relative dullness on the right. Over the dull area there was weakened vesicular breathing with prolonged and slightly blowing expiration. No adventitious sounds. Remainder of the lungs negative. The apex of the heart could neither be seen nor felt. The cardiac dullness was not enlarged. The first sound at the apex was weak but clear. The second sound was relatively louder and more abrupt. The second pulmonary was weak, distant and impure, and the second aortic was clearly heard. The pulse was full, quick, of good tension, and regular. Examination of the abdomen showed it to be pale, inelastic, walls lax and ribs and crests of the ilia prominent. Palpation negative. The prostate was enlarged, the right lobe being somewhat larger than the left.

Blood Examination—Red blood cells, 2,220,000, white blood cells, 6,800, hemoglobin, 42 per cent (Miescher). Differential count of 500 cells. Small lymphocytes, 40.4 per cent, large lymphocytes, 2 per cent, polynuclear neutrophils, 50 per cent, polynuclear eosinophiles, 5.4 per cent, mast cells, 0.0 per cent, degenerates, 1.6 per cent. Many macrocytes, microcytes, poikilocytes and oval cells. No nucleated forms seen.

Urinary Findings—24 hour specimen, 1025 cc., specific gravity 1.017. Acid. Color pale yellow. Tests for albumin and sugar negative. The small sediment contained a few leucocytes, epithelial cells and a few round granule cells. No casts.

Fecal Findings—The stools were small, thin and watery, brown, containing mucus in small flakes. No occult blood. Microscopically a few undigested meat fibers and starch were seen. No cells and no parasites found.

Test Meals—These showed an absence of hydrochloric acid. Total acidity low. Rapid motility. Low peptic digestion. No lactic acid. Microscopically a few short motile rods with curved ends.

Treatment—The patient was put on "anemic diet," consisting of eggs, raw beef and two hour liquid feeding. He was

given 10 grains of tannigen after each evacuation, a mild diuretic Blaud's pills in increasing doses, which was soon changed to Fowler's solution. He soon began to improve and progressed steadily. His blood became better so that at the end of a month the count was as follows (February 11) Red blood cells, 3,000,000, white blood cells, 3,600 hemoglobin, 50 per cent. The differential count showed small lymphocytes, 50 per cent., large lymphocytes, 25 per cent., polynuclear neutrophils, 32.5 per cent., polynuclear eosinophiles, 10 per cent., mast cells, 0.5 per cent., degenerates, 4.5 per cent. Though no nucleated cells had been found before this, they were now quite numerous. Normoblasts 13, megaloblasts 111. Many polychrome cells and a few stipple cells. A few days later the patient noted difficulty in urination. Burning sensation on passing and having to pass small amounts at frequent intervals were complained of. This continued for two days, when, on February 15, it was found necessary to catheterize the patient and withdraw a considerable amount of residual urine. Rectal examination at this time revealed, as has been previously described, an enlarged prostate, the right lobe particularly in this instance feeling soft. Immediately after withdrawing the urine the blood count was made. Red blood cells 1,710,000, hemoglobin 22 per cent. This was the first instance that we had in this case of an exacerbation of the anemia, as associated with retention of the urine. The only marked change in the differential count was an increase in the eosinophiles, which rose to 15 per cent., the neutrophils falling correspondingly. Nucleated forms were about the same as on the previous examination. The patient improved during the next few days, urinated freely, and except for weakness occasioned by the anemia, felt as well as previously. His blood remained about the same. The red count did not rise above that made on the 15th and the hemoglobin persisted at 22 per cent. The lowest red cell count was 1,040,000. On the evening of February 10, he again complained of severe pains in the lower part of his abdomen. He was restless, picked at the bed clothes, attempted to get out of bed, talked continuously, and showed other signs of active delirium. He had not urinated for eight hours. An examination of the abdomen revealed a distended bladder extending a hand's breadth above the pubis. The patient was catheterized at this time and 400 c.c. of dark yellowish red urine was withdrawn. Examination of this urine was as follows: Specific gravity, 1.017, clear and acid. No albumin, no sugar, no bile coloring matter. Strong test for urobilin. Sediment contained blood cells, some leucocytes and a few round granular cells. Unfortunately a spectroscopic examination was not made. A blood count made immediately after the catheterization showed the second enormous drop that had occurred in the course of the disease. The red cells were 740,000 and the hemoglobin was 19 per cent. From this time on until his death, February 23, the count remained practically the same.

Dr. Cunningham, in his conclusions, argues that the relapses of the anemia brought about the "weakness of the general muscular system of the bladder wall," which "lost its contractile power and retention of urine resulted." To my mind another factor was at work in both of our cases influencing both the exacerbations of the anemia and causing in part the retention. Prostatic hypertrophy brought about retention of the urine in both his and my own case, following this an absorption of the hemolysins occurred and remissions in the blood count resulted.

Sudden and rapid variations in pernicious anemia have been noted under many conditions. Not alone alterations in the differential count and the occurrence of nucleated showers, but changes in the red cell count and hemoglobin content frequently occur. Physiologic influence and secondary infections are the most usual causes in the daily variations in proportion between mono- and polynuclear white elements. Megaloblastic showers are regarded as an attempt on the part of the bone-marrow cells toward regeneration of the red cells. At the same time the clinician has looked on these flood-

of megaloblasts as a signal, prognostic of dissolution soon to follow. Diminution of the red cells and hemoglobin, slowly and with no attempt at regeneration, with slight but appreciable daily decline marks the progressive pernicious case. And *vice versa*, gradually increasing count after the ebb has been reached, with no other features than a steady rise in the count and a tendency on the part of the red elements to assume uniform shapes, signifies regeneration and convalescence. Remarkable increases in the hemoglobin and gains in the red cell count are so rare that their occurrence due to bone-marrow activity must be regarded with suspicion. Usually circulatory disturbances or faulty technique explain them. Sudden and distinct reduction in hemoglobin and drops in the red cell count are not so uncommon. They result from a variety of influences. Secondary infections cause the largest and most sudden drop in the red count. Especially is this effect seen resulting from septic infections. Excitement, increased mental activity or excessive physical exercise is followed at times by such remissions. There are times, however, when rapid fall in the blood content of the body can no more be accounted for than the disease itself. These idiopathic changes must be closely related to the primary causes of the anemia, for it seems reasonable that a rapid hemolysis can occur only when an excess of those hemolysins that produce the blood changes are in circulation.

Morris examined the urine of several cases of pernicious anemia along with the urines of other chronic and a few acute infectious diseases for hemolysins. He used 10 c.c. of urine and 10 drops of a 5 per cent solution of blood (rabbit) which had been defibrinated and washed free from serum. After incubation for two hours at 37° C. and then standing at 0° C. for 24 hours the specimens were examined macroscopically and spectroscopically. There was positive hemolysis in all cases of pernicious anemia at various times during the examinations, also hemolysis in hypnotic urines. In all other cases hemolysis was negative. It is evident from this that certain substances are excreted by the kidneys in pernicious anemia that have some hemolytic action on the blood. That these substances also circulate in the vessels of patients with pernicious anemia is evident from the work of Niesser,² Ascoli,³ Halpern,⁴ Ford and Halsey⁵ and others.

McCaskey⁶ found in a case of typical pernicious anemia a large amount of xanthin bases which "held in a one-twentieth of 1 per cent solution made isotonic for blood exerted a positive but slow destructive effect *in vitro* on normal erythrocytes." These, he thought were in much greater concentration in the urine than in the blood.

It has been disputed whether or not hemolysins were a part of the blood serum. Maragliano,⁷ in 1892 showed that hemolysis in anemia was due to a toxin of the serum rather than disease of the blood-forming organ themselves. Ford and Halsey have shown that hemolysis takes place when normal blood is subjected to laked blood.

Warthin⁸ maintained that the 'hemolytic poison' does not confine its effects to the portal areas as claimed

by Hunter, but is present in the general circulation.

The hemolysis of pernicious anemia does not differ in kind from that occurring normally or in certain diseased conditions. The difference is one of degree only." It seems evident from the above that when a retention of urine occurs in pernicious anemia that those substances or hemolysins which fail to be excreted are, in part, retained in the general circulation and, in part, reabsorbed into the body from the urinary tract. That these substances may cause a hemolysis, such as was observed in this case, is plausible, and that their continued retention may give rise to frequent remissions in the course of the disease is a logical conclusion.

Intermittent or cyclical hemolysis is the rule in pernicious anemia. Consequently when the poison that is normally being excreted from the kidneys is added to those already active in the circulation increased hemolysis is to be expected.

Whether this substance is a part of the serum itself or a toxin circulating in the blood requires further investigation. As mentioned above, there are many diseases in which a higher degree of hemolysis can be demonstrated in the blood serum than in pernicious anemia. In none of these, however, could Morris⁹ find hemolytic properties in the urine, unless there was a hypotonicity in the urine. This is interesting in the light of certain theories that are advanced as to the cause of pernicious anemia. The view of Hunter¹⁰ as to the cause of pernicious anemia—that the small intestine is the site of a specific infection whose toxin acting in the portal system alone causes hemolysis—needs further explanation. The recent work of McCaskey,⁸ though alluring, is inconclusive, in that only one case of the kind has been examined. Moreover, we do not know the amount of xanthin bases that may be present in other diseased states, nor the amounts that may be excreted by a healthy individual.

Another question that presents itself is whether or not all the erythrocytes that are destroyed at the periods when the cyclical hemolysis occurs undergo dissolution in the spleen and other hemolymphatic structures? It would seem as if hemolysis could occur in any vascular channel of the body, providing a hemolysin or toxin were present. This would liberate blood-coloring matter and, as stated above, the laked blood could exert an additional hemolytic action. Whether the hemoglobin from the blood cells, that could be broken down in this manner in the general circulation, is first carried to the liver, spleen and lymph glands, and then excreted as urobilin or whether it is excreted directly after having been changed to hemochromogen, has been investigated, but without uniform results. If the hemolysins act in the general circulation, it is probable that the red cells are disposed of in both ways. It must be remembered in this connection that the larger part of the blood passes through the portal system, and then through the liver and spleen, before it reaches the kidneys through the systemic circulation.

These two cases have suggested new problems that might be undertaken with profit—the constancy of hemolysins in the blood in pernicious anemia and in the urine, together with their relation both qualitatively and quantitatively, the absorbability of these substances, and the presence of products of hemolysis in the urine. There is need also of a method for estimating hemolysins whereby uniform results may be obtained.

THE FIELD WHEREIN THE WORK OF THE SURGEON APPROACHES THAT OF THE PHYSICIAN

CHARLES C. ALLISON, M.D.

Surgeon to St. Joseph's, Wise Memorial and Presbyterian Hospitals
OMAHA

Cases in which a reasonable doubt exists as to the propriety of an operation are met sufficiently often to warrant their consideration.

THE SURGEON AND THE PHYSICIAN

The training, character of practice and experience of the general surgeon differ in a measure from those of the internist—their observations being made from a different point of view, but their conclusions, when based on all of the evidence, should agree.

The experienced surgeon possesses an advantage from his opportunities to inspect and to palpate the living tissues and to study the pathology in its various degrees of severity and stages of progress and to compare such findings with the pre-operative symptoms. Repeatedly thus to study the symptoms before operation, and to check up the findings revealed by the exploration, contributes in the most practical way to the development of his judgment.

The relatively greater experience of the internist in his study of chest lesions is an aid to his interpretation of upper abdominal diseases, and from greater refinement in percussion, more accuracy in estimating blood pressure, and more experience in making blood examinations there accrues valuable clinical data for his consideration.

Beyond the question of diagnosis there is room for team work in planning the treatment. Some good surgeons develop into therapeutic nihilists, and some good physicians are tardy in recognizing the limits of medical therapy. Their combined efforts toward reaching a humanly correct diagnosis in the obscure case needs to be supplemented when an operation is begun by the utmost exercise of judgment in deciding on how much to do and in determining what supplementary aids will be most valuable in the after management.

AIDS TO SURGERY

At this period it is not necessary to refer to certain scholastic clinical pictures in illustration, but they afford a good opportunity to introduce borderline cases, for example, plastic repair in gynecology, when done for the more minor lesions, must not be expected to correct an existing gastroptosis or to benefit an atonica gastrica or to cure what is often the major feature of the case, malnutrition depending on secretory deficiencies or mechanical displacements of the digestive organs, with a pretty generally co-existing mucous colitis.

If lacerations need repair, and the proper anatomic position of the uterus requires surgical restoration, let this be accomplished neatly, selecting that form of surgical replacement indicated in the particular case, but the aid of an abdominal support, and particularly a study of the feeding of the patient will probably outweigh the operative steps in contributing to complete convalescence in this class.

The wishes of the patient or of the family must be final in deciding on an operation, but ours is the duty to mold opinion, and particularly must there be reserved abundant latitude to exercise our judgment as to the extent of surgery done, based on the exigencies of the case and their relation to the powers of resistance.

⁹ Morris. *American Jour. of Med. Sci.* 1904 p 1026
¹⁰ Pernicious Anemia.

A promise to do everything that is necessary in order to avoid a second operation should not be made, as this might clearly invoke unjustifiable risks to life, but permission should be given the surgeon to correct a co-existing lesion uncovered by the exploration when the risk of such procedure is but reasonable in degree. In weighing these problems, the surgeon will have much satisfaction if the support of the attending physician has been expressed in council.

UNUSUAL CLINICAL TYPES

Unusual expressions of pain often require most faithful efforts for correct interpretation, e g., a condition so remote from the pelvis as a weakened anterior arch of the foot may produce lumbar or pelvic distress from faulty habits of walking or standing. In verification complete relief has been seen to follow an appropriate support for the transverse or for the posterior arch of the foot.

On the other hand it was once my experience to investigate carefully the cause of a persistent and practically disabling pain radiating from a point near the middle of the crest of the ilium, for which the patient was wearing an elevated shoe. The local symptoms, however, were so impressive of an abscess, probably having origin from a deeply situated appendix, that an operation was advised and tardily accepted. A small abscess with thick protecting walls surrounded the tip of an appendix which lay almost entirely behind the peritoneum. It was clear that this abscess had existed for a considerable period. The high shoe has given no relief. In relating this case to a well-known orthopedic surgeon, he rejoined that he had once been called on to treat a case of sacro-iliac disease, for the relief of which an ovary had been previously removed by a gynecologist.

Recently the surgeon has been given greater latitude by the physician in dealing with cases wherein the sufficiency of the kidney has been in question, but this lesson, however useful for the future, has been learned at the expense of overdoing decapsulation.

THE REAL BATTLE GROUND

It is in the proximal right quadrant of the abdomen that the greatest difficulties in diagnosis are encountered. The anatomy is complex, functional activity is great, and a pathology beginning in one organ involves the contiguous tissues producing interdependent symptoms difficult to analyze, and the costal arch interferes in a measure with the usefulness of the surgeon's most reliable sense—palpation.

The outlines of the stomach are easily demonstrated, its mobility readily tested, and constrictions at the pylorus are easy to interpret—ulceration recognizable from fairly definite symptoms or by repeated examinations of the dejecta for blood, but infections extending through the duct of Wirsung to the pancreas or through the common duct to the liver cell and gall bladder are responsible for a pathology so variable in extent and degree that in my opinion there is opportunity for the exercise of the best talents of both the physician and the surgeon in making a diagnosis and there is need for supplementing the surgical treatment with therapeutic aid of a medical and dietary type.

Gallstones are incident to long-standing low-grade infections. They become recognizable from influences which are mechanical and their removal is generally called for by a condition so excited. The removal of the gallstones is essential for relief when they have become

mechanically troublesome, but the real benefit comes from the drainage of the bile ducts and liver cells. If we admit that drainage may be influenced favorably by dietary and medical aid by acting on the gastroduodenal mucosa, there remains at least a preventive field for the internist.

The final word concerning gallstones is yet to be spoken. That they are common, that they may exist without symptoms, that they may develop, be evacuated through the ducts and bowel and not re-form, at least for a period of years, is accepted. The last analysis, however, as to their bearings in heightening an infection, their relation to malignant disease, the amount of pancreatic disease secondary to their existence, and particularly their differentiation from diseases in contiguous organs are the problems remaining for further investigation and more complete solution.

ILLUSTRATIONS

In 1900, during convalescence from an operation for pelvic repair, Mrs. C. suffered from an acute biliary attack, with rigor, fever and jaundice. An examination of the stools revealed gallstones and an operation for drainage of the gall bladder was considered, but not thought to be urgent. No further attack was experienced and about the middle of 1906 it became necessary to remove an acutely inflamed appendix at which time the gall bladder and ducts were carefully examined. There was an adhesion of omentum to the fundus of the gall bladder, but the gall bladder was normal in size, easily emptied on pressure, no stones existing in the ducts. This case illustrates immunity for six years after a clear attack of gallstone colic and their recognition in the stools.

In 1902 at the termination of a difficult removal of a large, adherent multilocular ovarian cyst, the gallstones were detected in the gall bladder. The condition of the patient did not warrant their immediate removal. This patient has been under observation since that time and has had no symptoms referable to the bile tract.

In disease of the upper right quadrant of the abdomen four conditions primarily and in a major degree require the care of the diagnostician (Richardson). These are gallstones, gastric or duodenal ulcer, cancer of the stomach and functional diseases. Of these functional diseases represent by far the greater number of cases. Chronologically, malignant diseases will appear late and gallstones next, but the age can not be regarded as important in determining the probability, at least between functional diseases, gallstones and ulcer. More important is the character and degree of pain, the period of its occurrence, the amount of constitutional disturbance and its amenability to medical and dietetic treatment.

In gallstone pain as in the pain of extra uterine pregnancy there is a wide range as to degree, but it is well found that some particular attack has been sufficiently severe as to call for some prompt measure of relief and while these attacks of pain are thought to be produced by dietetic indiscretion yet the pain will be found to be rhythmic in its relation to the ingestion of food, thus the rule in functional disease.

THE DILEMMA

In gallstones it is well to remember that just as it is present in a minority of cases, probably not more than one-fifth, and it is usually in an older age group, its presence strongly suggests the possibility of a malignant disease.

pernicious anemia, in hypertrophic cirrhosis and in syphilis of the liver, not to mention that found in primary malignant disease of the ducts, must account for a number of cases of apparent jaundice, even though the tint in these diseases is, in a measure, characteristic

CANCER

Unfortunately, malignant disease of the stomach has no early pathognomonic symptoms. The usual location for the early development of the malignant disease is the cicatrix of an old ulcer, but its extension involves the submucosa primarily, and there is no ulcer to produce pain, and insufficient deposit to produce stricture or to impair the mobility of the organ in the early stages, therefore, recurrent spasm is not an early symptom. It is a disease, therefore, which we must diagnose largely from symptoms that are unobtrusive, but which fail to yield to the treatment which would favorably influence functional diseases or ulcerative changes in a reasonable time. Pain is not an early symptom, and to wait for vomiting of blood, great loss of weight, palpable tumor and cachexia or for the eyelet of the stomach tube or the test meal to reveal characteristic cells or, finally, to place any substantial dependence on the presence or absence of acid, is to clearly pass the period when curative treatment is possible.

Among the less frequent affections in the upper right quadrant of the abdomen, it has been my experience twice to encounter tubercular peritonitis, locally and primarily involving the peritoneum about the pylorus and gall bladder. In one the symptoms resembled malignant disease of the pylorus on account of the mechanical obstruction and loss of weight. In the other the symptoms were those of cholecystitis, which recovered after drainage of the infected peritoneum about the gall bladder.

Supra-umbilical hernia as a cause of pain, referable in my experience to the neighborhood of the left costal arch and uninfluenced by a treatment directed toward the digestive organs, yet sufficiently severe as to be at times disabling on account of the increased pain following physical exercise is frequently overlooked. This doubtless is due to the fact that it is comparatively uncommon, it may exist without causing any symptoms, and hence might be regarded as an innocent lesion, and the protrusion may be so small as to escape any except the most painstaking research. In the majority of cases it requires operative treatment for its relief. Occasionally it will yield to the accurate pressure of the adhesive plaster-cork support.

In the consideration of these diseases the degree of pain, the period of its occurrence, the direction of its radiation, its amenability to treatment, the amount of constitutional symptoms, the feel of the overlying muscles in the hand of the surgeon, the question of probability, and the ability to think of the unusual diseases which might resemble the clinical picture before us, must be weighed. At the same time the individual must be studied and his method of narrating his symptoms analyzed for the purpose of eliminating what is unimportant, yet to cross-examine on what is important, recognizing the symptoms to be typical or atypical before the final analysis is made.

THE STATE BOARD AND THE COLLEGE DIPLOMA *

MURRAY GALT MOTTER, A. M., M. D.
WASHINGTON, D. C.

One of the most interesting and significant features in the development of modern medical education is the relation between the state medical examining and licensing board and the medical school. As has been shown elsewhere,¹ there is reasonable ground for the belief that the state board sprang only from a soil mulched with the product of the decadent medical school. To put the point more bluntly, had the medical school done its full duty, there would never have been need of the state board, for the diploma of such a school would have satisfied all registration requirements. It must be conceded, therefore, at the very outset, that the state board begins its functions with a natural, not to say genetic, prejudice against the medical school *per se*.

In the prehistoric days of the profession, before the rise of the schools, its neophytes were the accredited apprentices of recognized practitioners. With the evolution of the healing art, it was found that mere empiricism was but a poor guide, that underlying all vital activities are certain fundamental laws and principles, certain necessary sequences of cause and effect, which, mastered, give man a certain more or less complete control over the ills to which he is heir. The knowledge of these fundamental laws and principles, of these sequences of cause and effect, constitutes the science of medicine. It was early apparent that no one man, busied with the claims of his patients—the more numerous, the greater his skill and fame—could impart to his student that full knowledge which would make him the worthy bearer of his preceptor's cloak. Hence it came about that two or three, or more, combined to give their students the benefit of their combined experience. Had each one but covered the same ground, the gain would have been merely quantitative, not qualitative. As elsewhere, throughout the organized world, development is marked by a differentiation of labor and a consequent specialization of function. The evolution of the physicist, the chemist, the anatomist, the physiologist, the pathologist, forms but a part of the evolution in the general history of civilization. As time went on, the medical profession came to be recognized as one of the learned professions, and its privileges and emoluments as something to be sought in themselves. The diploma, which conferred on its holder a right to these privileges and emoluments, came to have a value which tended to overshadow the duties which it imposed, and then, by easy stages of degradation, it became in many instances the mere commercial product of the diploma-mill. Then, and only then, did the public, recognizing the utter inadequacy of the diploma in itself, as a guarantee of capacity and ability, seek to protect itself by interposing between itself and the body which confers the diploma a disinterested board whose function it is to test the qualifications of the applicant for licensure.

The powers of these boards would seem to be sufficiently recognized and established, their duties are evolving with the progress of events. It will, perhaps, be universally admitted that some evidence of preliminary training should be submitted before the candidate is admitted to examination by the board, and that hitherto

Naming of Carbon Compounds—Esters are compounds in which the hydrogen ions of acids, organic or inorganic, have been replaced by organic radicals, thus acetic acid, CH_3COOH , and ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}$, form CH_3COO (C_2H_5), acetic acid ethyl ester or ethyl acetate.—*Pharm. Rev.*, August, 1906

* Read at the Sixteenth Annual Convention of the National Confederation of State Medical Examining and Licensing Boards, Boston, June 4, 1906.

1 THE JOURNAL, June 3, 1906.

the diploma has been at least the most convenient form of such evidence. Owing to the conditions just outlined, it has become necessary to discriminate between these diplomas and, in some instances, against certain institutions granting them. An indication of the former need is seen in the unanimous opinion of the Supreme Court of the United States, delivered Jan. 14, 1889, in the case of *Dent versus the State of West Virginia*. Speaking of the qualifications of the physician, Mr. Justice Field said

Reliance must be placed on the assurance given by his license [not diploma] that he possesses the requisite qualifications

Of the latter need there is evidence in the laws of the various states, wherein schools are referred to as of "good standing," "recognized," "reputable," etc. In the light of Judge Toney's significant definition (*Nelson versus State Board of Health of Kentucky*) it may be argued that the word *reputable* best suits the needs of the state board and should find its place in every licensing act. Says Judge Toney

The word "reputable," as used in the statute, applied to a college—an institution of learning—has a different meaning from what it has when applied to an individual. When applied to an individual, the adjective "reputable" has reference to his moral character, to his character or reputation as an honorable man, i. e., to his integrity and good character, but when applied to a college, the word *reputable* has reference to the extent of its course of sessions, that is, to the period of study required for graduation—to the thoroughness of the education required at such college—to the thoroughness of the course or courses of science prescribed and taught in said college, and to the capacity and qualifications of the teachers therein, and to the standard of scholarship and proficiency in said sciences required of the students as a condition precedent to the issuing of diplomas to them as graduates thereof

Again, said Chief Justice Strahan, of the Supreme Court of Oregon (*William Barmore versus the State Board of Medical Examiners*)

As a part of the current history of the times, and as in arriving at the legislative opinion, when there were different kinds of colleges authorized by the laws of the states in which they were located, in which there were pretended annually to be delivered full courses of lectures and instruction on the arts and sciences professed to be taught, that were not reputable, because they graduated students for money frequently without regard to scholarship, a diploma from such an institution afforded no evidence of scholarship or attainments of its holder. It was a fraud and deserves no respect from any body, and it was against such diplomas the law was intended to protect the public, and, therefore, required the colleges to be *reputable*. Whether a college be reputable or not is not a legal question, but a question of fact.

Once more, said Judge Given ("The Eclectic College Case," Supreme Court of Iowa, May, 1893)

The standing of the college, as contemplated by this statute is rather what the college is in respect to the thoroughness of its courses than what it is reported to be

Unfortunately, what a college is is not always to be learned with certainty from its official publications. In a paper read March 19 1906, at the sixteenth annual meeting of the Association of American Medical Colleges, one of the delegate members said

Until the medical colleges of this country can bring themselves to tell the truth in their catalogues they must not expect to receive any great confidence

At the same meeting another delegate said

The degree of doctor of medicine does not always represent what it should represent. The very existence of examining boards is evidence of the fact that all medical colleges can not be relied on. There are men engaged in educational work—

in secondary education and in professional education—who must be watched. That being the case, the examining board comes into existence, and the examining board needs information.

And now a few illustrations, the data furnished are drawn from material, most of it in print, and all of it at the disposal of this conference

Last fall the secretary of the State Board of Colorado sent a letter of inquiry as to the status of the Eastern University of Washington, D. C., with this was enclosed a wretchedly printed announcement of the institution aforesaid, which proposed to give full courses in the arts and sciences, in theology, medicine, dentistry, pharmacy, etc. No such institution was registered in the office of the commissioners of the District of Columbia. None of the faculty was to be found in the city directory, indeed, no local habitation was mentioned in the printed announcement. The matter was at once placed in the hands of the superintendent of police, who detailed a detective to look into it. Investigation developed the fact that all mail addressed to the Eastern University of Washington, D. C., was delivered at the office of an attorney in the city who, it is understood, makes a specialty of incorporating organizations of various kinds under the laws of the district, and by him forwarded, unopened, to a postoffice box in Philadelphia. Again no local habitation was given and the sumptuous lecture halls and well-equipped laboratories of this institution were—and still are—hidden under the ample cloak of "Uncle Sam's" mail. The next inquiry was made of the General Postoffice Department, whose inspector chased this specter out of the City of Brotherly Love and into New York and—back to Philadelphia! Repeated inquiries have failed to bring any more definite information. The health officer of the district, who was secretary of the Board of Medical Supervisors, the police department of the National Capital and the Postoffice Department of the United States Government seem alike unable to answer questions. No doubt, more than one member of this confederation has asked where and what is the Eastern University of Washington, D. C. While there is little doubt that any but the most unsophisticated would give credence to the pretensions of such a mere paper diploma-mill, the fact that it can so freely use the mails and so easily escape detection and localization is significant

If there be any city in the country where a night school of medicine might find a reasonable excuse for existence it is, perhaps, the city of Washington. The offices of the several governmental departments swarm with ambitious but underpaid clerks, many of whom work at their desks from 9 until 1:30, and many others seek to profit by the much-vaunted educational advantages of the National Capital from 4:30 until 9. Whether or not it is possible thus to serve two masters, without slighting the work of one or the other, it must, in sheer justice, be said that many able and capable men have entered the profession by this route. To-day, however, when the medical curriculum cries aloud for more time and for the undivided attention of its follower it is more than doubtful whether such a combined course can be followed either with safety or with profit. Could the medical course in such a school be extended to five or six years the last year being devoted unremittingly to clinical work and of course in the daytime but little criticism could arise. Competition, however, so long as that the medical school which turns out a graduate in four years at most would

On the other hand the

the

night school must be abolished, and in answer to the pressure thus brought to bear we find in one catalogue this rather unique announcement in bold face type

TWO COURSES OF LECTURE LABORATORY AND CLINICAL WORK WILL BE GIVEN DURING THE YEAR, THE ONE BEGINNING DAILY AT 9 30 A. M., THE OTHER AT 4 30 P. M. THE STUDENT MAY SELECT EITHER COURSE

It has been impossible to secure a printed schedule of these courses, for the reason, it is understood, that none has been printed¹. On the bulletin board, however, we may see lectures scheduled at 8 a. m. and then—a vast and significant vacuity until the mystical hour of 4 50 p. m. True, in the first year, the anatomic laboratory is open from 9 to 12, the physiologic laboratory, thrice a week, and the chemical laboratory, twice a week, from 2 20 to 4 50. In the second and third years there is pathology from 1 to 4 thrice weekly, in the third year there is physical diagnosis from 1 to 2 twice weekly, and in the third and fourth years a recitation in gynecology at 1 o'clock on Thursdays, but the bulk of the work is crowded, in each year, between 4 50 and 10 30. This school did not take kindly to the rule that preliminary education is to be passed on by the state authorities, or at least not by the faculty of the medical school. Its dean asserted with some warmth that, of course, his school would reserve the right to pass on the qualifications of its own matriculants.

In reviewing the obstacles to further progress, in the cause we here represent, the chairman of the Council on Medical Education of the American Medical Association said last year

A second obstacle, and one of great moment, is found in the medical colleges which are conducted as private corporations. There can be no longer any excuse for the existence of a medical school which is conducted by a body of men for profit. It is only necessary to state the demonstrated fact that it costs more to furnish a student with a medical education than he pays for fees to show conclusively that a school supported solely by the fees of the students, and which pays a profit to its owners, is doing poor work and has no warrant for existence. Fortunately, with the increase of requirements, especially for preliminary education, these medical schools will be forced either to seek endowment or absorption by universities which will enable them to do acceptable work, or else they will be condemned to extinction by the law of the survival of the fittest.

Let us consider, for a moment, a school of this type. The connection between a certain other university and its medical school might be called a *mariage de convenance*. The president of the university is, *ex officio*, president of the medical faculty, but the latter is practically autonomous, its treasurer disburses all funds on the order of the faculty or its duly authorized committees and these committees are appointed by the vice-president who is, of course, a medical man. There is no endowment and the dividends of the professors are determined by striking a balance between the total fees received from students and the total running expenses of the school.

In THE JOURNAL you will find what was said to be its curriculum "in force during the session of 1903-1904". A few stray items are not only illustrative but interesting. In the first year we find twenty lectures and twenty hours of laboratory work assigned to physics. There was not then, and there is not now, a physical laboratory in this medical school, nor did the class have any laboratory work at all in physics. Seventy-five lecture hours are assigned to physiology, the class actually had fifty-two recitations. Forty hours' laboratory work are assigned to physiology in both first and second years. As

a matter of fact there was no physiologic apparatus worthy the name until the opening of the following session and absolutely no laboratory. The first class to have laboratory work in this school had twenty-five hours for each student during the session of 1904-1905, and the equipment consisted of two scant sets of the Harvard physiologic apparatus, increased in the summer of 1905 to eight sets.

If a committee of this confederation will take the time and trouble to compare the data given in the annual "Educational Number" of THE JOURNAL with the catalogues and lecture schedules of some of these institutions, it will find some "mighty interestin' readin'."

Let us see something of the quality of the output of such a school as shown by a few extracts from examination papers.

The red blood cells, through their property of holding in combination oxygen for the nutrition of the body, carrying it to every part of the organism from the air cell walls of the lungs and returning carbon dioxide constitute the external respiration.

On the function of the vasomotor nerves, we have this statement:

The pressure is increased or diminished by these nerves—the nerves are a part of the sympathetic nervous system and have their center in certain ganglia situated on each side of the spinal cord in the main chain of the sympathetic system.

Foods may be absorbed in any portion of the alimentary canal after digestion but the great majority enter the blood through the walls of the stomach and the small intestine. They enter as simple sugars, the starches having undergone a hydrolytic process, or as peptones and albuminoses, as inorganic salts and fats.

This is from a graduate of 1903, though you will not find his name on the printed commencement program of that year, and he is to-day unable to pass the local board of examiners.

By consulting the reports published in THE JOURNAL since Jan. 1, 1906, you will find there recorded to the discredit of this same institution four failures in Connecticut, three in the District of Columbia and one each in California and Maryland. Last spring, out of a class of twenty-seven students of this school, fourteen were haled before the faculty for cheating in one of the final examinations. The commencement program shows that there were sixteen graduates in June. The "Announcement for the Session of 1906-1907," just issued, states that the degree of M.D. was conferred on twenty-five candidates in 1905, there is no hint as to how they were distributed throughout the year.

But why go further into details, which could be multiplied *ad nauseam* and probably from a much larger number of schools? It must be apparent that, especially in the unendowed schools, this condition is practically a commercial necessity. In order to pay dividends to the members of the faculty, these schools must graduate their matriculants. It is devoutly to be hoped that the newly aroused public sentiment, which is seeking to purge the atmosphere in the financial, political and social worlds, will permeate the professional world as well. Without the aid of public opinion, which is, after all, the court of last appeal in this country, we can do little or nothing. Meantime, however, we can at least be honest among ourselves. We know that the 4 000-hour schedule, over half of which is devoted to clinical and laboratory work, requires an equipment and personnel not to be found in these institutions. We

know, if from nothing else than the printed proceedings of its recent annual meeting that even membership in the Association of American Medical Colleges is not a sufficient guarantee of good work well and conscientiously done.

Better things will come, not through fear of the occasional visit of the peripatetic inspector, whose inspection must, of necessity, be hurried, superficial and all too brief. Better things will come only when the general sentiment is aroused on the educational map. Pub-true state of things. We all know well where these desert spots are located on the very generally recognized toxin for the cancer of fraud. The comparative tables published in *THE JOURNAL*, together with the weekly reports of failures before the several state boards, can not but have a salutary influence.

But there is still another side to this question. Until the state boards be raked out of the muck of politics, until their examinations be raised above the mire of catch questions and mere memory tests, until these examinations be genuine tests, not of mere learning, but of knowledge, of capacity, of ability, of character they will, some of them, be no more *reputable* than some of the colleges of which we have been thinking.

CONTRIBUTION TO THE STUDY OF ERYTHEMA INDURATUM (BAZIN)*

LUDWIG WEISS, MD.
Attending Physician to the Skin and Genitourinary Service, German
Poliklinik, Consulting Dermatologist, Hebrew Orphan
Asylum
NEW YORK CITY

Besides those dermatoses which are known to be of tuberculous origin, like lupus vulgaris, tuberculosis verrucosa cutis and scrofuloderma, there are to-day numerous other skin lesions regarded as closely related to tuberculosis, if not entirely of tuberculous origin. One of them, lichen scrofulosus, the older Hebra regarded as associated with tuberculosis. He found that 90 per cent of patients so afflicted were youthful individuals, with cervical and other kinds of lymphadenitis, perionitis, caries, or affected with ulcerating scrofuloderma, symptoms which are characteristic of what we call "scrofulosis," making the name of lichen scrofulosus a proper one. In some inveterate cases of this disease acne-like lesions appear with or without pus formation. Hebra called them acne cachecticorum. He found the so-called pityriasis tabescentium. A third affection brought by him in connection with tuberculosis is chromophytosis. It appears with predilection in those phthisical patients who are affected with seborrhea and hyperidrosis.

TUBERCULOSIS AND CUTANEOUS DISEASES

A group of other skin affections more or less closely allied or even identical, but known under different names, have of late been brought into the domain of the octopus tuberculosis. These are folliculitis exulcerans (Lukasiewicz) or hydroadenitis suppurativa (Pollitzer), Kaposi's acne telangiectodes Barthelemy's acnitis and follicles, known also as papulo-necrotic tuberculides or necrotic granuloma (Johnston's). The sarcoids of

Boeck, the pityriasis rubra et annularis, the angiokeratoma, the lupus erythematosus, the much contended lupus erythematosus, and the keloid are regarded as associated with tuberculosis. The erythema induratum, Bazin's group, called by Darmer an important group of tuberculides, is a matter of fact that the important group of tuberculides is derived from the evolution of this group of tuberculides. The grouping of seemingly different tuberculides into a system of common etiology is at first glance surprising. While lichen scrofulosus, acne cachecticorum, as mentioned before, were thought to be associated with scrofulotuberculous taint, the real import of such a connection could at that time only be surmised, but not determined. The histologic features of Jacobi,¹ who found bacilli in his two patients in lichen scrofulosus identical with the structure of the tubercle, also Sack,² Boeck's and Hutchinson's³ investigations, finding the same element in the disseminated form of lupus erythematosus, and finally the researches of Hallopeau, Darmer,⁴ Brocq⁵ and others gave the impetus for further studies in this line.

We must look on the tuberculous taint as a predisposing cause or, rather as a favorable culture medium for the acquisition of different skin lesions. Unfavorable circulatory conditions in their wake may produce lupus pernio or angiokeratoma. But there certainly must be a more intimate association with tuberculosis in such lesions in which, although the bacilli have not been found, histologic examination revealed tuberculous features. These are follicles, Boeck's sarcoids, lupus erythematosus, etc. In a series of other lesions like lichen scrofulosus, Jacobi and more recently Wollf⁶ have demonstrated tubercle bacilli, while Haushalter,⁷ Pellizzari and others have reported positive inoculation results. Again in erythema induratum, although bacilli could not be demonstrated, yet Thibierge and Ravaut,⁸ also Carlé,⁹ succeeded in obtaining positive results by inoculations.

These different results gave rise to two kinds of hypotheses as to the origin of these lesions. They are held to be due either to the toxins of the bacilli, located somewhere in the body, or to the bacilli themselves, dead or alive, which are carried to the skin by the blood current and there act as a morbid factor. The former are aptly called toxic tuberculides and the latter bacilli-tuberculides.

REVIEW OF LITERATURE AND PATHOLOGY

It would exceed the limits of this paper to analyze the abundant literature on this subject. Briefly said, the theory of toxic tuberculides has its main representative

in Klingmüller,¹⁰ who supports his contention with the fact that injection of tuberculin has caused the appearance at the point of injection of lichen scrofulosus lesions and emphasizes his hypothesis by the lack of tubercle bacilli in the lesions, their acute onset, benignant course, discrete appearance, spontaneous involution and non-inoculability on animals.

In 1890 I saw such lesions at Schwenninger's clinic while he and Buzzi were experimenting in the early days of Koch's tuberculin. At the same time I also witnessed the so-called local and general reaction take place in established cases of lichen scrofulosus, also in some cases of lupus erythematosus. Unfortunately with the disappointment at that time to find a "sure cure" in Koch's great invention for all cases of phthisis, gathered at Berlin in midwinter, these experiments were not pushed and were forgotten. In contradistinction, Mracek¹¹ holds tuberculides to be bacillary tubercloses of hematogenic origin and fortifies this contention by the demonstrations of bacilli and positive inoculation results cited before. That the tuberculides as well as the classical tuberculous affections of the skin are both of hematogenic origin, with the exception of the inoculated forms *per extra*, is an attribute common to both. Neither does the inability to demonstrate the tubercle bacilli in the tuberculides vitiate against their being of tuberculous origin. Furthermore, we know how difficult of demonstration they are even in true tuberculosis and how rarely we succeed in inoculating experiments. From all these conditions common to both forms one can perceive that the class heading of tuberculide or tuberculos of the skin is an arbitrary one. Among these tuberculides, erythema induratum Bazin stands in its relation to tuberculosis about third on the list, being preceded by lichen and acne scrofulosus and the papulo-necrotic tubercle. In about more than half of the reported cases it was proven associated with tuberculosis. In extremely rare instances the bacilli were found in the lesions, especially by Wolff. In other instances inoculation on guinea-pigs proved positive (Thibierge and Ravaut,⁸ C. Fox,¹² Carlé⁹ and Jadassohn¹³), while in other cases the tuberculin test in the patient proved positive (Mracek,¹¹ Mantegazza,¹⁴ Hartung and Alexander,¹⁵ Sollner¹⁶ and myself). Histologic and bacteriologic examination also show different opinions. Audry¹⁷ regards it as non-tuberculous, Lerédde,¹⁸ Thibierge and Ravaut¹⁹ hold it to be of tuberculous origin. The latter demonstrated the main changes in the vessels: endothelial proliferation almost to the point of occlusion, giant cells with peripheral nuclei and numerous epithelioid cells.

One of the most constant findings is the atrophy of the subcutaneous fat tissue into large cysts and transformation into connective tissue. The clinical picture of erythema induratum is well characterized. Bazin²⁰ describes it as occurring in red hard nodes, paling at compression, tough or doughy to the touch and extending into the subcutaneous tissue. The formations do not

itch and are only slightly tender on pressure. The affection is localized with predilection on the legs, anteriorly, on the calves and laterally. It is more frequent in girls than in boys. Neither Bazin or Besnier²¹ nor recently Jarisch²² alludes to any changes taking place in these nodes. They describe them as undergoing absorption.

Conditions became somewhat confused when Hallopeau and Lerédde,²³ Hutchinson,²⁴ C. Fox,¹² White²⁵ and others reported ulcerating cases which greatly resembled scrofuloderma ulcerosum. Doubtless many cases of the latter have been taken as erythema induratum and *vice versa*. A non-ulcerating subcutaneous scrofuloderma occurring in young people and occupying the lower extremities is, indeed, apt to be confounded with the node of erythema induratum. I venture the opinion that these formations are so closely allied to each other that neither clinical nor histologic or bacteriologic differences can hold them apart without diagnostic artifices. Even the ulcerating form of erythema induratum has many similarities with ulcerating scrofuloderma, although I admit that the caseating undermined reactionless scrofulogummata with their extensive skin destruction will permit of some differentiation especially when it started from a lymph gland and much more so when on other parts than the lower extremities.

The localization of the lesions on the legs may be regarded as the classical feature of erythema induratum. Sluggish circulation, impaired *vis a tergo*, are the main causes of its appearance there and also of lupus pernio or simple pernio so frequently accompanying this trouble. While the disease almost exclusively affects females, yet in rare instances it has also been found in men, and, although it is most frequently met in adolescent girls and young women, yet of late it has been found in older women also. Johnston²⁶ found it in association of what is called to-day papulo-necrotic tubercle on the hands and forearms. He calls these affections paratubercloses.

DIAGNOSIS

The diagnosis of erythema induratum Bazin has in a great measure been alluded to previously, out of which the picture of the disease can be construed without marked difficulty. These are the salient points: formation of subcutaneous deep-seated nodules, more easily recognizable by touch than by sight. They develop into hard deep-seated indurated nodes, not adherent to the skin at first, but becoming so later. The skin is at first purplish, then as the nodes become larger and work toward the surface it changes into a dull violaceous hue. In size they occur from that of a cherry or even double its size. They also occur on both sides of the Achilles tendon. Their cause is eminently chronic, their development and behavior tardy and of slow activity. In those rare instances when they break down, necrosis sets in on the summit of the node in one, rarely in several places, attended by a scanty seropurulent discharge. The final scarring and pigmentation is then not so pronounced as that of an ulcerous scrofuloderma.

ETIOLOGY

As regards their etiology, the association of erythema induratum in half of the cases with the tuberculous

taint, its occurrence chiefly in women sometimes also affected with circulatory disturbances, has been alluded to. In more than 50 per cent of cases the tuberculin test proved positive. To reconcile this etiologic discrepancy, Whitfield²⁷ in 1900 and again in 1905 asserted that there exist two well characterized types of the affection: a tuberculous and a non-tuberculous. The former, attacking young women, is of an indolent character and presumably due to the living tubercle bacilli, the latter, occurring in middle-aged women affected with circulatory disturbances, is of a rheumatic nature, more painful, prone to break down and not allied to tuberculosis.

CASE REPORT

The following is the history of my case:

History—Mrs. M. M., aged 26, Russian, married, has no children, no history of lues, but has mitral trouble. A nephew has a tuberculous taint.

Nine years ago, in winter of 1896, she noticed a lump on the inner aspect of the left lower leg. She was given a salve, which, in the language of the patient, "took out the inflammation." The lump eventually disappeared. In the meantime, however, several others appeared, one on almost the same spot and another on the right leg. All of them disappeared

sistent tumors from the size of a split pea to that of half a walnut, and situated in the direction of the long axis of the body. As those on the lower legs developed they worked themselves toward the surface and became purplish, without, however, any one of them breaking down. Those formations which were situated on the thighs and nates were invisible and could only be determined by careful palpation as deep shot like, hard bodies distributed in the subcutis. They were very painful, annoying her while sitting but did not develop further. While under observation for over five months my

FIG. 1.—Interstitial connective tissue of the subcutaneous fat showing hyperplasia, new formed connective tissue and new lymphatics.

in May 1897. In the winter of 1897 lumps appeared again in about the same region but not in the same situation. They disappeared in the summer of 1898. For five years no recurrence took place when in November of 1904 lumps again appeared to the right and left of the Achilles tendon of the left leg and on the calf of the right. Patient could hardly walk and had to stay at home for a week. All lesions disappeared in May.

In November 1905 she left the house well and in walking. On rushing painful sensation in her right leg. When she had home she noticed the appearance of the lumps. She particularly states that she had always had lumps. This time on the right leg other thigh, over the nates. Only slight

Examination—On the right and ten on the

associates and I noticed the spontaneous disappearance of the undeveloped ones first and of the others later.

A week's treatment with iodid of potash and salicylate of soda had no influence on them whatever, and as they had disappeared previously without any medication nothing more

FIG. 3.—Interstitial connective tissue of the subcutaneous fat showing hyperplasia, new formed connective tissue, and new lymphatics.

was done. At the time of the report the lumps were still present on the right and left.

A review of the case of erythema induratum will show that the disease is characterized by the appearance of lumps on the lower legs, which are painful and may break down. The disease is more common in women than in men, and is often associated with tuberculosis.

²⁷ Am. Jour. of the
1901. Also Brit. Jour.

congenital nutral affection, showing a slight stagnation hyperemia on both cheeks so frequent with heart affection, exhibits a sluggish chronic disease of *perennial* appearance and of the described qualities and peculiarities. The presence of a scaling lupus pernio (possessing almost the character of a lupus erythematosus) on four toes of the left and three of the right foot, extending over the metatarsal joints, is another important concomitant symptom so frequently mentioned by investigators. The second etiologic symptom is the positive result following the tuberculin injection. The patient had a stormy reaction, 24 hours later there was a temperature of 103 and a great deal of general disturbance. Inoculation on guinea-pigs taken from one of the excised formations proved negative.

The onset of the affection with pains, reported by Thibierge and Ravout, and Hartung²⁸ was present in a very marked degree. As to localization, I think this case showed a distribution of the lesions hitherto unobserved in the same patient. The occurrence of deep nodules *ad nates* has, to my knowledge, not yet been described. Close observation showed that they did not develop further and that none of the lesions broke down

sum, especially those which are coexistent with the lesion of erythema evadativum multiforme, cause visceral lesions so classically described by Osler, or in turn may be the effect of such systemic infectious diseases. In tuberculous meningitis this is frequently the cause and leads one naturally to consider the assertion of Uffelman,³¹ Baumler³² and others who believe in the association of a pernicious form of erythema nodosum with tuberculosis, the patients mostly having been descendants of tuberculous parents. It may be that erythema nodosum and erythema induratum are only different stages of the same process, with a slightly varying etiology and pathology. There is another evidence of the admissibility of such hypothesis by the occurrence of one or more of these tuberculides on one person. These tuberculides or paratubercloses as Johnston calls them, have transition stages. Lichen scrofulosus has been seen with erythema induratum, with the papulo-necrotic tubercle or necrotic granuloma of Johnston,²⁶ with follicles or cutaneous tubercle described by Macleod and Ormsby,³³ etc. It is probably better not to adhere too slavishly to disease headings, which sometimes are only the result of arbitrary divisions.

Fig. 4—Giant cell with coarse protoplasm and vacuole

The nearest approach to such a condition was a slightly doughy condition in the centers of the fully developed lesions. It is furthermore noteworthy that the formations would make their appearance in winter, then disappear and others reappear, the course of the whole process taking from four to five months ending with the approach of summer.

In this respect my case resembles that of Burns,²⁹ as regards the unusual number and distribution which suggested erythema nodosum, except for the long period it lasted which is incompatible with the latter. The two cases of W. Pick³⁰ which he calls persistent erythema nodosum occurring in two young women with no evidences of tuberculosis have very much in common with both forms of erythema. There are undoubtedly transition stages between the different tuberculides. Lichen scrofulosus seems to be a higher development of lichen scrofulosus. Certain cases of erythema nodo-

Fig. 5—New connective tissue with epithelioid cells and giant cells resembling a tubercle

The histologic features of my case are in harmony with the description of other investigators, but with slight deviations. An increase of the interstitial connective tissue framework (hyperplasia) (Fig. 1). An atrophic degeneration of the subcutaneous fat tissue (Figs. 2 and 3), and formation of giant cells (Fig. 4) with radiating nuclei and epithelioid cells (Fig. 5), and endothelial proliferation of the vessels were present. These changes in the subcutaneous fat tissue are only characteristic of tuberculosis when other concomitant symptoms bear them out. In my case the vessel changes were not so prominent as to produce thrombosis and, in a sense, this would vitiate against the theory of a hematogenic origin. But their absence could be explained by the fact that the very smallest capillaries might have been already destroyed by the fatty degeneration of the embolic plugs.

ERYTHEMA INDURATUM—WEISS

1187

DIFFERENTIAL DIAGNOSIS

The transition forms of erythema nodosum have been alluded to. In a general way erythema induratum can easily be differentiated from erythema induratum by the acute character and intensive systemic disturbances. Its lesions are more superficial, more painful and appear more suddenly in the color and more in inflammatory in their character. They rarely, if ever, break down and their absorption takes place in a manner resembling the color changes of a fading contusion. Hence the name dermatitis confusiformis. Again, erythema induratum has a chronic course as a rule does not but may break down in a small number of cases, and is not connected with the stormy systemic disturbances and yields a more evanescent pigmentation. In differentiation from syphilitic gummata, which it resembles strikingly, I may mention, that gummata will never appear so numerous, neither will their appearance be attended by systemic disturbances. Again, a gumma will not exist for months without changing if absorbed, it will do so by local or general mercurial treatment. The confusion with lepra, to which it bears a far-away resemblance, is not very imminent. As the question of the tubercles is as yet in a very undecided condition and the etiology and pathology of erythema induratum is not quite settled, the reporting of every case is a duty incumbent on the observer. In conclusion I regard it my pleasant duty to express my gratitude to Prof. Harlow Brooks M.D. of the Department of Pathology University and Bellevue Medical College New York City for his painstaking pathologic and bacteriologic examination of this case and also to Henry Kreuder, M.D. New York City for the preparation of the microphotograph.

DISCUSSION

Dr. A. RAVOGLI, Cincinnati, said that he has always been firmly convinced that erythema induratum is an expression of tuberculosis. In support of this he mentioned the case of a man who accidentally injured his finger a splinter entering underneath the nail. This splinter carried with it the infection from the saliva of a tuberculous patient and subsequently an ulcer developed at that point, which proved very persistent. This was followed, in the course of time by little reddish points in the line of the lymphatics of the arm. These were hard and indicated an erythema induratum. They gradually developed into ulcers and proved very little doubtless resulted from the original inoculation under the nail. The lesions were thoroughly ulcerated and the patient eventually made a perfect recovery. Another case reported by Dr. Ravogli was that of a young woman who had a number of lesions on the calf of the leg. These persisted for some time without causing any trouble. Some of them disappeared entirely but one of them ulcerated and had the appearance of a tuberculous lesion. This patient finally died of tuberculosis. Dr. Ravogli said that the cases he has seen of erythema induratum have led him to believe that it has no connection with tuberculosis. The lesions in erythema induratum are only of a transient character and without serious consequences. Dr. M. L. HIRSHBERG, Cincinnati, said that in spite of the experience of Dr. Ravogli he still regards tuberculosis as a perfectly safe drug to use and he has never seen any deleterious effects from it. He has found the American products unreliable and he recalled cases in which their injection had failed to produce any reaction although tuberculosis was unquestionably present. In using tuberculin is reliable but that it has not deteriorated. Dr. Heringfeld said that the value of tuberculin as a diagnostic factor is demonstrated by the case which Dr. Ravogli cited as an instance of erythema

induratum (Bazin). Dr. Heringfeld said that patient at a later stage and was convinced that the case was one of syphilis, after four weeks of internal treatment with mercury and potassium iodid and mercurial ointment externally, the lesions cleared up entirely. If tuberculin had been used early in that case the true character of the lesions would doubtless have been recognized. In a case of syphilis which he saw last autumn there was a double infection with one chancre on the lip and another on the vulva. The case ran a rather severe course in spite of energetic treatment and large doses of masses developed on the leg and other parts of the lower extremities. These were first regarded as gummata in character but mixed treatment had no effect on them and they subsequently proved to be tuberculous. In that case an injection of tuberculin produced a decided reaction and helped to establish the diagnosis.

Dr. JAMES C. WHITE, Boston, said that he believed he was the first to describe this affection as occurring in this country. He observed a type of chronic deep nodular induration of the lesions being of considerable size. They occurred on the lower extremities and did not run the course of those seen in erythema nodosum. On examining the literature to find a record of such instances elsewhere he came to Bazin's description of this affection to which they bore a close resemblance. As time has gone on he has seen cases which were apparently connective links between the typical lesions of erythema induratum and other conditions of the skin of faces of the lower extremities but it is now admitted that similar lesions are found more widely distributed over the body. They are sometimes of smaller size and are not confined exclusively to the lateral and posterior surfaces. It is so called tubercles which have more recently been described.

Dr. LEONARD WEISS, New York City, said that in a recent search of the literature he found a case closely resembling that mentioned by Dr. Ravogli which Jadassohn has reported under the name of tuberculosis multiplex subcutanea. The lesions in that case developed within a few weeks and then broke down leaving fistulous openings. The description did not perfectly tally with that of erythema induratum. Dr. Weiss does not believe that in the classical erythema induratum of Bazin the lesions are apt to break down the same is true of erythema nodosum and he thinks that the cases recorded as having broken down lesions did not all belong to this type. Dr. Weiss said that it is over 10 years since Dr. White's article first appeared in the *Journal of Cutaneous and Genitourinary Diseases*. In that article Dr. White had a premonition of the discrimination that should be made between different tuberculous lesions of the skin and warned the dermatologist not to cling too slavishly to any particular classification of diseases Dr. Weiss regards tuberculin as a valuable diagnostic factor although he recalled one instance of doubtful tuberculosis in which the disease was aroused to activity by an injection of tuberculin and rapidly caused a fatal tuberculosis of the lungs. With the minute doses used at present such an accident is not likely to occur.

Prognosis in Typhoid Fever from Temperature After Cold Baths.—Marchand gives the details of 7 cases of typhoid fever in which the temperature in the axilla was taken regularly 20 minutes after each bath. The baths were given at 26° C (78 F.) for 15 minutes and the number of baths ranged from 16 to 100 in the different cases. In some of the cases the temperature after the bath was found reduced by 1.17 to 1.25 degrees C (24 degrees F.) and the patients who were up all succumbed to the disease. In the patients who were up the reduction in temperature never surpassed 0.8° to 0.9° Centigrade (1.6 to 2 degrees F.). In the latter group were some very severe and rapid tuberculosis in which the temperature in the axilla was taken 10 minutes after the bath and the temperature in the rectum was taken 10 minutes after the bath. In the latter group the temperature in the rectum was found to be 0.1 to 0.2 degrees C (0.2 to 0.4 degrees F.) higher than the temperature in the axilla.

There are two disadvantages to the method of fastening the fundus directly to the abdominal wall

First—There is a decided uncertainty as to the amount of forward suspension or fixation that will be secured. The object is to form a short band that is strong enough to hold the uterus forward and upward, but that will not interfere with the development of the uterus in pregnancy. From this ideal the uncertainty extends in both directions, i. e., the suspension band may become so slight and attenuated that it fails to keep the uterus forward or, on the other hand, there may result a firm fixation of the fundus to the abdominal wall that causes serious trouble during pregnancy or labor. These undesirable results have occurred often enough to make them valid objections to the operation, but not often enough to warrant us in discarding the operation in conditions in which a better one is not applicable.

Second—There is danger of the formation of a long slender band with which the intestines may become

entangled. That portion near the uterus and the weak part is that portion near the abdominal wall.

Some depend on the weak part of the ligament for holding the uterus forward, while others depend on the strong part. In the former class, folding the ligament is a method which has been modified by many operators. This method with its modifications was used extensively for several years and with excellent results in many cases, but it was found that relapse occurred rather frequently, due to the stretching of the attenuated portion of ligament entering the abdominal wall at the internal ring.

Then came the method of drawing the ligament into the abdominal wall until the uterus was supported by the strong proximal portion. This was accomplished either by grasping the ligament within the inguinal canal and drawing it out through the internal inguinal ring or by drawing it through an artificial opening in the musculo-aponeurotic wall near the median line. In either case, the ligament was drawn out until the uterus was suspended by a short cord consisting of the strong part of the ligament next to the uterus. In the first method, that of drawing the ligament out through the internal inguinal ring the effect on the uterus was the same as in the Alexander operation.

There are several variations in the method of reaching the inguinal canal. Sindberg reaches the canal from the longitudinal median incision by pulling skin and subcutaneous tissues far to the side, loosening them from the aponeurosis of the external oblique as necessary.

Peterson makes a transverse suprapubic incision and from each end reaches the inguinal canal of that side.

Montgomery puts a ligature about the round ligament some distance from the uterus, threads this ligature into a long curved pedicle needle and through a window snipped in the anterior peritoneal layer of the broad ligament carries the point of the pedicle needle and the ligature beneath the peritoneum to a point near the inguinal ring. Here the needle is carried through the muscular and aponeurotic structure of the abdominal wall and toward the median line where it emerges in the abdominal incision beneath the skin and subcutaneous fat.

Barrett also fastens a ligature on the round ligament but instead of carrying it outward in the broad ligament and into the abdominal wall by a pedicle needle he introduces a curved ligature carrier in the shape of a forceps from the abdominal incision just beneath the upper sheath of the rectus muscle outward to the internal inguinal ring through which it enters the abdomen, then follows along the round ligament subperitoneally to the ligature. Here it is brought through a small window made in the peritoneum and the ligature threaded into it. It is then withdrawn bringing the ligature with it. By means of the ligature the ligament is drawn out as far as it will.

Dudley in order to draw the ligament into the abdominal wall through the upper incision in the wound, draws it to the peritoneal cavity.

Fig. 3.—The left round ligament drawn into place. Notice that the direction of pull on the uterus is changed from internal to anterior. At the same time there is no large opening between the distal portion of the round ligament and the anterior abdominal wall requiring a suture, as in the regular Clifton Ferguson operation. The distance from the peritoneal exit of the new ligament to the internal edge of the peritoneal cavity at this level is so small (represented in the corner sketch in Figure 2 by the distance from *b* to the internal inguinal ring) that it is closed by moderate traction on the distal portion of the round ligament loop appearing in the wound. If it is desired to bring the uterus farther forward the proximal portion of the ligament is pulled on. If the peritoneum becomes tense before there is sufficient tension on the round ligament to bring the uterus well forward the peritoneum over the ligament loop may be incised and the ligament itself grasped and drawn out as desired.

entangled producing acute intestinal obstruction. This has happened a few times but I think the frequency or probability of its occurrence has been greatly exaggerated.

Both of these disadvantages may be avoided by using the round ligament for holding the uterus forward. For their utilization there are several methods applicable after the abdomen is open but one point should be kept in mind, namely that the strong part of the round ligament

into the peritoneal cavity without touching the incision. This he accomplishes by putting a temporary ligature on the ligament, threading this into a large curved blunt needle, passing the needle into the internal inguinal ring or near it through the aponeurosis, then along for some distance above the aponeurosis and then through the aponeurosis and peritoneum again into the cavity a short distance from the median line.

In all these operations, the exit of the ligament from the abdominal cavity into the strong musculo-aponeurotic portion of the wall is through the internal inguinal ring or very close to it, i. e., the direction of the pull of the ligaments on the uterus is not changed. Consequently these have the same element of failure that has caused disappointment in certain cases following the Alexander operation and its modifications. The normal exit of the round ligament is placed too far laterally to hold the uterus well forward when there is much tendency to go back after replacement. This has been noted repeatedly by operators, and, in fact, it has long been an established fact that the function of the round ligaments is to exert forward traction on the uterus not in its normal position, but only when it is in marked backward displacement.

I am not condemning the Alexander operation nor its modifications. It is an excellent operation in certain well-selected cases. I have used it with good results and have watched it through pregnancy and labor and afterward with the utmost satisfaction. But I have found that it is not applicable in certain cases of apparently freely movable retro-displacement, namely, in those cases in which there is a persistent backward pull, as evidenced by the tendency of the uterus to go backward as soon as the replacing fingers were removed. In such cases it is likely to result in partial failure, the uterus being found in moderate backward displacement after a time. Likewise, a shortening of the ligaments after abdominal section by drawing them through the internal inguinal rings may result in the same partial failure if there is much tendency of the uterus to go backward.

In the second general method above mentioned, that of drawing the ligament through an opening in the musculo-aponeurotic wall nearer the median line, the pull of the supporting portion of the ligament is changed from a transverse toward an anteroposterior direction, with a consequent marked increase in its ability to hold the uterus and adnexa well forward.

There are several variations in the method of changing the course of the ligaments. It will not be necessary to mention all of them. The Gilliam-Ferguson operation stands as the type of this class. Gilliam passed a temporary ligature around the ligament from 1 to 1½ inches from the uterus. The skin and subcutaneous tissues on that side of the abdominal incision were then pulled aside and a sharp-pointed artery forceps was introduced through the fascia, muscle and peritoneum into the cavity, where it grasped the ligature and brought it out. With the ligature the round ligament was then drawn out as desired and the ligament of the other side was treated in the same manner. Ferguson

added a puckering suture to bring together the parietal peritoneum and the distal portion of the round ligament, thus doing away with any opening through which a knuckle of intestine might slip and be caught.

G. H. Noble succeeds in satisfactorily changing the direction of the ligament and shortening it by the following method. He enters the abdominal cavity through a transverse suprapubic incision made in the usual way and completes the intra-abdominal work. Then at one end of the transverse incision, just beyond the margin of the rectus muscle, an artery forceps is thrust through the posterior sheath of the muscle, but not through the peritoneum. The forceps is opened and withdrawn so as to make an aperture in the aponeurosis large enough to admit the finger. The finger is then introduced and carried along the peritoneum and the aponeurosis to the internal inguinal ring where the round ligament, made tense by being caught within the abdomen and pulled on, is felt. The finger is hooked about the ligament which is

Fig. 4.—The use of the puncturing tenaculum forceps in the regular Gilliam-Ferguson operation. The puncture is made directly through the upper sheath of the rectus muscle, the lower sheath and the peritoneum, and the ligament grasped and brought out—the puckering suture having been previously passed. After the ligament is brought out as desired the puckering suture is tied thus closing the opening at the side between the distal portion of the round ligament and the anterior abdominal wall.

drawn into the wound. The ligament is then drawn out to the desired extent, its peritoneal sheath being stripped back toward the uterus. The other side is treated in the same way and the two ligaments fastened together over the rectus muscle.

It will be noticed that in this operation the new point of entrance of the ligament into the strong aponeurotic wall is at the outer margin of the rectus muscle. The peritoneum is sufficiently movable on its underlying structures to permit this shortened ligament to extend almost directly from the angle of the uterus to the point of exit at the outer margin of the rectus muscle thus

SUCCESSFUL REMOVAL OF AN EIGHTY-NINE-POUND CYSTIC MYOMA INTACT

As will be noted from the following history, this patient was cognizant of the fact that the tumor had existed for over 20 years. At that time she was under the care of Dr. James Bosley, the present health officer of Baltimore. Further, it will be seen that this large growth did not prevent her from looking after her household duties until recently, and less than three months before the operation she took a 180-mile trip with no ill effects. This, so far as we can learn is the largest myoma of the uterus that has been successfully removed. The patient is now, eight months after the operation, in perfect health and is gaining rapidly in weight.

CASE 1.—Mrs. McA., aged 58, was seen in consultation with Dr. Marshall Smith, June 25, 1906.

History.—Twenty years ago she noticed a tumor in the lower abdomen and later was seen in consultation with Dr. W. T. Howard, emeritus professor of gynecology in the University of Maryland, who at that time advised an operation. Some time after this she was delivered of a healthy child, now 18 years of age. This patient, although suffering from a large abdominal tumor, was able to go around and to do her work until three weeks before I saw her. Her chief inconvenience had been her inability to lie on her back in bed. And sometimes when she would get "stalled" it was necessary for her husband to turn her over quickly otherwise she would have suffocated. For

two weeks before admission she had a temperature sometimes reaching as high as 103 F. She was admitted to the Church Home and Infirmary July 27, 1906. There was considerable edema of the lower part of the abdomen and some edema of the legs. On admission to the hospital her temperature was 100 F., pulse 105. On the morning of operation the temperature was 100 F., pulse 100, respiration normal.

Fig. 3.—A large parasitic myoma which weighed 15 pounds and was attached to the uterus by a pedicle 1x5 cm. At the top is a broad omental adhesion carrying vessels to the tumor. At b is a cross section of a portion of the rope of omental vessels which pass down beneath the tumor to c and then turn upward again plunging into the tumor. a represents one of the largest vessels which stand out prominently. Crossing these large vessels are numerous adhesions. c is a portion of the large vessel which passed down perfectly free from the omentum to the under surface of the tumor.

Fig. 2.—Cross section of a cystic myoma weighing 89 pounds. The pedicle is clearly seen and in the fresh specimen is not over 1.5 cm. in diameter. Attached to the top over the pedicle are the tube and ovary and near the tube is a piece of liver substance. The tumor has been converted into one large cavity the walls of which consist of muscle. In the walls are numerous cystic spaces particularly well shown at the points indicated by a. There are several large cystic dilatations in the wall. The largest is indicated by b. The myomatous walls vary from 5 cm. to 1 or 2 mm. in thickness. At the point c where the tumor lay over the vertebral column the wall is exceedingly thin. The entire inner surface is lined by partly organized blood clots which give the growth a very shaggy appearance. The entire tumor was filled with blood. The outer surface of the tumor in many places covered by adhesions containing large vessels.

Operation. July 30, 1906. Prior to receiving the anesthetic the patient was thoroughly washed and all preparations for operation were made so that she might remain as short a time as possible under ether. It was impossible for her to lie down consequently she was operated on in the sitting posture. An incision was made over the most prominent part of the tumor and I attempted to puncture it. The growth, however, started to bleed and no cystic fluid escaped. I continued the incision upward for the reason that many large veins projected into the tumor from some structure above. The incision was gradually continued upward until the sphincter was reached (Fig. 1). We found that the large vessel going to the tumor was omental in origin and that they were spread out over the entire upper surface. Some of them were fully 7 or 8 mm. in diameter. The tumor was densely adherent to the anterior and to the lateral abdominal wall. These adhesions were gradually shelled off with the hand but I had to use the uterine forceps and do all liberating under sight as the rupture of one large vein might have caused the loss of blood. The hemorrhage could have been controlled by the use of the uterine forceps. The vessel passed from the stomach and

pedicle of the tumor was not more than 1.5 cm, in diameter and was situated directly beneath the ribs. On removal of the tumor I found that I had brought away a piece of liver tissue 3 cm in diameter. We had no liver needles handy, so I used sharp Hagedorn needles, running the eye through instead of the sharp end. This device answered admirably and the liver bleeding was easily checked by four catgut sutures. The uterus and the right tube and ovary lay under the surface of the liver. Anticipating the possibility of great difficulty in controlling the tumor, we had prior to operation sterilized a large foot bath and covered it over with a sterile sheet. The foot bath held about one third of the tumor and the person who took charge

patient on admission to the hospital weighed 174 pounds. Twenty-three days after operation she weighed 80½ pounds. The condition of the abdomen in this case was particularly interesting. I did not even resect a portion of the abdominal wall, because we had to save as much time as possible during operation. At the first dressing it was noted that the ribs extended out fully 6 inches from the abdomen and that the recti muscles lay on the bed on either side, while there was a good deal of loose and wrinkled skin covering the abdomen. Another interesting point was that the gauze, which drained the extraperitoneal pocket just at the symphysis, now lay in the middle of the abdomen as the tissues were gradually contracting. After the lapse of two weeks the recti muscles could be felt gradually contracting and coming in and the costal arch was flattened down to some extent. When I examined her six weeks after operation the recti muscles were well up in the abdomen, being not over 10 cm apart. The skin had contracted down wonderfully. The pendulous skin over the symphysis had retracted to a marked extent and the ribs were almost in their normal position. At the time of operation there was a good deal of edema of the abdominal walls. There was also edema of the legs and of the buttocks. Although the utmost care was used, a bed sore developed several days after the operation, there being a black slough over the sacrum 6 cm in diameter and surrounded by a faint red halo. It had resulted from pressure on the table. The patient had marked edema of the back, but was forced to sit up during almost the entire operation. After she went home she rapidly regained her strength. The bed sore gradually diminished and in time entirely healed. It is astonishing that she had so little inconvenience after the operation.

Description of Tumor—Miss N. Ellicott, superintendent of nurses, weighed the tumor immediately after its removal, the net weight, after deducting that of the vessel in which it lay, was exactly 89 pounds. The thin part of the tumor lay posteriorly, otherwise we might have evacuated the tumor. Had we done so, however, it would have been much more difficult to have gotten at the large vessels, which we encountered at

Fig. 5—Pregnant uterus the fetus and placenta intact. After the uterus had been well hardened the anterior surface was removed. The cervix presents the usual appearance and the uterus is firmly contracted around the fetus. The head lies in the upper portion. The left arm is firmly adherent to the left side of the chest and the skin is macerated to some extent. Situated in the lower part is the placenta which extends slightly over the internal os.

of it was able to guide the tumor in the desired direction without allowing it to slip from his grasp. The tumor was drawn downward and outward and finally delivered from the abdomen. In the lower part it was extraperitoneal. I closed the abdomen, but left a small cigarette drain in the extraperitoneal pouch just over the symphysis.

Postoperative History—The patient stood the operation well, but was commencing to collapse by the time we finished. She was under ether for one hour and twenty minutes, 200 grams of ether were used. The operation, from the incision to complete closure, took fifty-five minutes, a much longer time would have been consumed had it not been for the combined assistance of both the Johns Hopkins and Church Home staffs. The patient's temperature rose to 102.2 F within eight hours after operation, but dropped to 100 F by evening. The highest pulse rate was 130. There was no postoperative vomiting. The legs were bandaged on account of the edema. The patient voided urine on the evening of the day of operation. She was catheterized only once. The usual after treatment was employed. On the fourteenth day she had considerable discomfort from frequent stools. The diarrhea persisted off and on for a couple of weeks. At this time, however, the weather was excessively hot and diarrhea was general throughout the hospital. It affected chiefly those patients who were somewhat weak. The

Fig. 7—Chorioepithelioma. The specimen consists of a uniformly enlarged uterus. The cervix is perfectly normal; the body was as large as that of a five-months pregnancy. Occupying the entire body of the uterus is a new growth with many depressions and cystic spaces extending into the wall. The growth itself presents a peculiar porous appearance (b) and the finger-like process so characteristic of carcinoma is absent. In the lower part of the uterus the outer muscular walls are still clearly seen, but in the upper part of the cavity the growth has extended almost to the peritoneal surface. The growth could hardly be mistaken for anything else. It is remarkable to see such a uniform involvement of the entire uterine wall. a indicates clearly the sharp line of demarcation between the malignant growth and the outer muscular covering.

almost every point. Had this condition persisted much longer the posterior wall of the tumor would certainly have given way and then operation would have been almost out of the question. As it was, the hardened specimen collapsed of itself when placed on the table.

Macroscopic Examination (Gyn and Path No 10382).—The hardened specimen is about 50 cm in length, 45 cm in breadth and approximately 25 cm in thickness. Over the entire anterior surface and laterally are numerous adhesions. Attached to the upper border is an area of omentum 20 cm in breadth and the hardened vessels range from 5 to 6 mm in diameter. The pedicle of the tumor is 15 cm in breadth, 1 cm in thickness and the portion removed is 15 cm in length. Situated just beneath the pedicle and attached to the surface of the ovary is a piece of liver substance 3 by 2 cm (Fig 2). On pressure the tumor in part seems to be solid, in part cystic. At operation when I attempted to puncture the tumor, nothing but blood was encountered. The growth is, however, evidently made up of one large cystic space and numerous smaller ones, together with the semi solid area. Over the part that is cystic the muscle fibers have been greatly stretched and thinned out and there are little hernial projections, the picture being analogous to that found in a slightly sacculated urinary bladder. On section the greater part of the tumor is found to consist of one cavity, which is approximately 42 by 35 cm. The walls vary from 2 mm to 5 cm in thickness. Only at one point is the wall very thin, namely, on the under surface where it lay over the vertebral column. The greater part of the wall consists of simple myomatous tissue, but at numerous points small cystic areas are visible and the tissue has undergone the characteristic hyaline transformation. One of the cysts measures 2 by 3 cm. The inner surface is covered with blood and the greater part of the tumor is filled with blood, which has undergone coagulation during the hardening.

Microscopic Examination.—On histologic examination the growth is seen to be made up of typical myomatous tissue. In many areas hyaline transformation has taken place and at some points there is typical liquefaction. The inner surface of the cyst has no epithelial lining, it is covered with blood which is faintly organized.

Dr Herbert P. Cole in looking over the literature for me, has found in all about 240 cases of large tumors of the uterus.

The largest authentic successful case found was that of Clarence Webster. The tumor weighed 87 pounds. This was also a cystic myoma and much of the fluid was removed before the tumor was extirpated. Among other successful cases is that of Eastman in which the tumor weighed 60 pounds.

There are numerous instances of tumors weighing from 40 to 60 pounds. Keith, for example, reported one of 52 pounds, and in Dr Kelly's service at Johns Hopkins we have had very large ones. Knowsley Thornton reported an instance of a fibrocystic tumor weighing 91 pounds, Tait reported one of 68 pounds, and Stockard one of 135 pounds. Stockard's patient died after tapping. McIntyre of St. Louis operated on a patient with a tumor weighing 93½ pounds. The woman died of peritonitis.

Platonoff saw a patient with a tumor weighing 90 pounds. Two unsuccessful operations were performed and the woman died of gangrene without removal of the tumor.

Hunter speaks of a 110-pound tumor seen at autopsy. Gilliam says that 200-pound tumors have been seen. Such data, however, are hardly reliable unless careful histologic examinations have been made. The tumor in Webster's case weighed just two pounds less than ours. The operation was performed Dec. 16, 1902. There were numerous adhesions and the entire growth was removed under Schleiss' solution and a few drops of chloroform.

Those wishing to get full data on this subject should read the articles by George W. Johnson,¹ G. Piquard,² Joseph T. Johnson,³ McIntyre⁴ and Clarence Webster.⁵

A LARGE PARASITIC MYOMA WITH MARKED DEVELOPMENT OF THE OMENTAL VESSELS, SOME REACHING 1 CM IN DIAMETER

At Johns Hopkins Hospital we have been studying with a great deal of interest the gradual weaning away, as it were, of pedunculated myomata from their parent blood supply in the uterus. As the pedicle becomes smaller the blood supply from the omentum becomes more vigorous until eventually the uterus forms an insignificant source of nourishment and the omentum, as in this case, sends in very large vessels. I have studied a large series of such cases, which will be published by Dr. Kelly and myself at a later date. In the more advanced cases the omental fat disappears completely and the vessels lie just between two peritoneal folds. In this case the cord of omental vessels forming a rope 6 cm in diameter seems almost unique.

CASE 2.—C, a colored patient of Dr. Scheller, of Hagerstown, was admitted to the Hagerstown Hospital, Aug. 4, 1900. She had had an abdominal tumor for five years. The tumor rose abruptly and projected fully 18 inches from the general abdominal contour. The vagina posteriorly was greatly encroached on.

Operation.—On opening the abdomen a tumor was encountered which was adherent everywhere to the anterior abdominal wall and also laterally. Running into the anterior surface of the tumor from its upper end were blood vessels, some of them nearly 1 cm in diameter. They were spread out over an area 16 cm in breadth. Passing down the right side of the tumor and lying beneath it was a regular rope of blood vessels (Fig. 1). These lay perfectly free from the surrounding structures, could be lifted up, were covered with peritoneum and were evidently omental, but no fat was present. These vessels formed a mass 6 cm in diameter and looked and felt like small masses of snakes. They could be traced down to the lower end of the tumor where they spread out over its surface and plunged into its substance. One of the vessels 5 mm in diameter, passed down by itself and lay absolutely free. It was isolated for a distance of 18 cm, being devoid of any attachment whatever. It originated in the omentum and extended downward and plunged into the tumor. After liberating the vascular supply we found that the tumor was attached to a small myomatous uterus. The pedicle was 3 cm in breadth, 5 mm in thickness and contained but one blood vessel of any size. The pedicle was cut and the tumor delivered. In the vessels passing from the omentum we encountered, as a rule, one artery and two veins. The artery was about one third the size of a vein. As the patient's condition became rather serious, although she had not lost more than two ounces of blood, we ceased the operation, the patient still retaining her myomatous uterus and a second myoma fully 25 cm across. This also had vessels from the omentum plunging into its upper part and was attached to the uterus by a pedicle 2 cm in diameter. As soon as the patient regains her strength thoroughly I hope to remove the uterus and the large parasitic myoma.

Result.—The patient made a satisfactory recovery and left the hospital about six weeks after her admission.

Description of Specimen.—On examination of the hardened specimen, it is found to be 23 cm in length, 25 cm in breadth and 20 cm in its anteroposterior diameter. It is markedly nodular, exceedingly hard and weighs 18 pounds. The upper omental attachment (all clinging to the tumor) is 17 cm in width and 8 cm in length. The omental attachment that ran down

the side of the tumor consists almost entirely of blood vessels. Its attachment at the lower border is 20 cm broad. Even in the hardened state some of the blood vessels are nearly 1 cm in diameter.

DEATH OF FETUS WITH SUPPURATION, PERFORATION OF UTERINE WALLS, SUPRAVAGINAL HYSTERECTOMY, RECOVERY

This case demonstrates how Nature, if left alone, may successfully ward off an attack of general peritonitis. Here there was suppuration in the uterine cavity, numerous perforations of the uterus—fortunately situated entirely in the anterior wall—and then successful walling off by the abdominal wall becoming adherent to the uterus.

CASE 3—A. P., colored, aged 21, was admitted to the Cambridge Hospital, March 4, 1906. The patient had been thought to be pregnant one year before. She had been carefully watched for some time, but no further developments had taken place. She had had some slight fever. Nothing more definite could be learned, however. When I examined her the cervix was soft, the uterus was globular and lay half way between the umbilicus and the xiphoid. The growth was apparently somewhat movable.

Operation—I made an incision over the growth and immediately came in contact with what looked like grumous material, which suggested a suppurating ovarian cyst. As the tissues were densely adherent, I continued the incision upward

Fig 1—Tremendous abdominal enlargement due to a cystic myoma. The abdomen is markedly and uniformly distended and the growth extends down almost to the knees. It will be noted that there is no sagging in the flanks. Coursing over the surface were very large vessels. When it is realized that the abdominal incision extended from the xiphoid cartilage down over the entire length of the tumor and then back to the symphysis it is readily seen that the incision was nearly 4 feet in length.

and opened up the general peritoneal cavity. On loosening the other adhesions I found the omentum adherent. This was clamped and cut. The tumor was intimately blended with the thickened abdominal peritoneum. It was shelled out as rapidly as possible, but pus oozed from the surface in various directions (Fig 4). I thought that I was dealing with an ovarian cyst, but was surprised to find on releasing it from the adhesions that it was the enlarged and globular uterus. I amputated through the cervix. The tubes and ovaries were covered by a few slight adhesions, but were otherwise normal and were left behind. It was with the greatest difficulty that enough peritoneum was obtained to close the abdomen, as so many raw areas had been left where the uterus had been adherent to the abdominal wall. A gauze drain was introduced into the lower part of the incision. The patient improved rapidly and left the hospital feeling perfectly well.

Description of the Uterus (Gyn and Path No 9810)—The specimen consisted of an irregular and globular mass approximately 18x17x15 cm in diameter. Its surface was everywhere covered by adhesions, and at numerous points were openings irregular in shape and varying from 3 mm to 5 mm or more

in diameter. Through these openings quantities of pus welled out during the operation. The pedicle or cut surface was 4 cm in breadth, 3 cm across and in the central portion of this was what looked like the cervical canal. On opening the specimen after it had been hardened we found that this tumor was the uterus (Fig 5). The walls varied from 15 mm to 4 mm in thickness.

Fetus—Snugly filling the entire cavity was a fetus (Fig 5). The length of this fetus from elbow to axilla was 7 cm, from elbow to shoulder 8 cm. The breadth of the fetus in the axillary line was 13 cm. Other measurements could not be made on account of the distortion of the child, but it appeared to be an eight month fetus. The skin was somewhat macerated. The child had evidently been a mulatto, as in many places the mottled appearance was still present. At other points, however, the outer skin had been rubbed off and the surface had the pale appearance of a white child. The hair which was matted up against the uterine wall was curly and black and several centimeters in length.

Placenta—The placenta occupied the lower quadrant of the uterus and projected over the cervix, there had been a partial

Fig 4—The perforated pregnant uterus as seen on removal. It is everywhere rough and covered by adhesions. In the lower part of the field is seen the stump of one tube. At points *a a* are perforations of the uterus whence pus was seen oozing out, at *b b* the walls are exceedingly thin, there have been many adhesions and pus is lying on the surface. One would not for a moment take this to be the uterus except for the presence of the tube.

placenta prævia. The placenta at the thickest portion was 2 cm in thickness. Attached to the surface of the child, especially in the vicinity of the hair, was much friable, yellowish material. This looked very much like inspissated pus. It was from the surface of the uterus at points of perforation that the purulent discharge came during the operation.

Sections of Uterine Wall—Sections from the uterine wall showed that the outer surface, at certain points, particularly where it was adherent to the abdominal wall, was covered by numerous adhesions. On the protected side cuboidal cells were visible. The muscle at such areas showed a great deal of small round celled infiltration. The inner lining of the uterus was much altered. There was a good deal of canalized fibrin and also regular ribbons of hyaline and canalized fibrin. Just beneath the surface and on both sides of this were numerous small round cells and polymorphonuclear leucocytes. At a few points calcified villi could be made out. Decidual cells were still in evidence but they had become smaller.

Remarks—There had evidently been a chronic inflammation of the inner surface of the uterus coupled with an inflammatory process on the outer surface at the points where the uterus was

adherent to the abdominal wall. In this case there had been death of the fetus for some cause or other and discharge or absorption of the liquor amni. Suppuration had taken place in the uterine cavity. At some points the uterine walls had become perforated and the pus had trickled out over the surface. Fortunately, no intestines lay in the way and the pus had glued the uterus to the anterior abdominal wall. This is certainly one of the rarest conditions to be met in the literature.

ABDOMINAL PREGNANCY OF FOUR YEARS' DURATION, OPERATION, RECOVERY

In this case there was a typical history of a pregnancy going on apparently to term. Labor pains developed and soon ceased and the patient retained a tumor for between three and four years without any marked discomfort. It is certainly remarkable that this abdominal tumor persisted so long without giving rise to any alarming symptoms. The nourishment of the abdominal pregnancy was, of course to a great extent furnished by the omentum.

Fig 6.—Abdominal pregnancy of four years duration.—The illustration is an exact reproduction of the abdominal contents and has been drawn from the specimen. The uterus is normal in size normal in position. Attached to its right side is a large pus tube which is densely adherent to the sac. On the left side the structures are not clearly outlined, as the broad ligament was intimately attached to the pregnant sac. Passing over the anterior surface of the sac in its upper portion and considerably flattened is the transverse colon. Densely matted to the surface of the sac is the omentum. In the upper part of the sac a window has been cut out and to the left a hand at the top a foot, and between these two and lying in the vicinity numerous tufts of hair represented in black may be seen. The sac passes down and almost completely fills Douglas pouch. This tumor had lain in the abdomen nearly four years. Apart from the adhesions to the transverse colon the intestines were perfectly free.

CASE 4, Gyn No 13272—J. A., colored, married, aged 28, was admitted to the Johns Hopkins Hospital from the dispensary Sept 27, 1906.

History—She complained of pain and swelling in the abdomen. Her general health had always been good and she had never consulted a physician before. Her menstrual history was unimportant. She had been married fifteen years and had

had four children, the eldest nearly 15 years old. The second child was deficient mentally but lived five years. The third was 10 years and the youngest 8 years of age. Her labors had all been normal, there had never been any miscarriages. For some years she had had a slight amount of thick, white, foul smelling discharge, more marked before and after her menstrual periods than at any other time. For several years she had been constipated, the bowels not moving for two or three days at a time. She had passed no blood nor mucus.

Present Illness—About four years ago she noticed a small lump in the lower part of the abdomen. This was the size of a baseball situated below and to the left of the umbilicus. The tumor increased in size at a uniform rate and the patient thought she was pregnant. At the end of nine months the tumor reached above the umbilicus. The breasts were enlarged and contained colostrum. The patient had had no nausea or vomiting. Her menstrual periods had been regular, although she had had a very scanty flow. She was certain that she had felt movements of the child. About the time that labor should have come on she had bearing down pains beginning in the evening and lasting until early morning. The pains ceased then and never returned. The patient thinks that she has never had any other signs or symptoms since that night. The breasts gradually became soft and dried up. The tumor seemed to decrease slightly in size. No movements were felt and the patient suffered no discomfort. She became convinced that she had a tumor.

Symptoms—Until about a year ago she could go about her work without difficulty, but then she began to notice a little soreness and the "tumor began bothering her."

Within the few months previous to admission she had felt an increase in the amount of soreness. She had had headaches at times, her tongue had been coated, she had frequently felt nauseated but had not vomited. After walking a good deal there was a burning sensation in the lower part of the abdomen, and during the last two months the headaches had been quite severe. The patient had to stop work on account of the burning pain that would come and go. This pain was eased by lying down. She slept well, but her appetite was poor and she said she did not gain in weight. There was no pain nor burning on defecation or urination.

Examination—Dr. Hutchins, the resident gynecologist, found the patient rather emaciated. The abdomen was distended rather more on the left than the right side by a tumor which rose from the pelvis and reached 4 cm above the umbilicus in the median line. The tumor felt cystic, it was movable, dull everywhere on percussion and no fluid wave was noted. On vaginal examination no evidence of infection could be found. The cervix was firm. There was slight bilateral laceration. The uterus was in ante-position, normal in size and apparently in no way connected with the abdominal tumor. Movement of the tumor did not draw the cervix upward. Clinically, the tumor was thought to be an ovarian cyst or a myoma, but no definite diagnosis could be made.

Operation—Sept 28, 1906. After making a long abdominal incision it was found that the abdominal cavity was occupied by a large "tumor of the left ovary," to which were adherent the omentum, the entire transverse colon, a portion of the sigmoid, and the ascending colon. The uterus was densely adherent to the right side. The omentum was tied and cut, a portion being left attached to the tumor, the proximal portion being reflected backward with the transverse colon. In doing this the thin wall of the tumor was ruptured and an ounce or two of thick creamy, yellowish material escaped. This was rapidly sponged up and further escape controlled by pressure with gauze. In order to avoid infection, so far as possible, the right tube which had been converted into a pus sac and was adherent to the cystic tumor was liberated. The broad ligament on the left side was clamped and cut so that the tumor could be shelled out of the pelvis and tipped over to the left side. In this way the grumous contents of the cyst were prevented to a great extent from escaping into the abdominal cavity. After the tumor was shelled out there was a great deal of bleeding from the mesocolon. This bleeding was checked as far as possible by sutures and the transverse colon was then curved in on itself so that the mesocolon formed a funnel. A gauze drain

was introduced into this as it dropped down on the pelvic brim and was brought through the vagina. In this way we were able to check the bleeding almost completely. The abdomen was closed without drainage from above.

Result—The patient made a very satisfactory recovery and was discharged Oct. 21, 1906.

Description of Tumor (Gyn and Path No. 10417).—The specimen consists of an abdominal tumor which was connected with the left broad ligament and the left tube and ovary. It was absolutely free from the uterus, which was not removed. The specimen in the hardened state measures 24 cm. in length, 18 cm. in breadth and 16 cm. in its anteroposterior diameters (Fig. 6). Attached to its right side are the right pus tube and the right ovary. To its left are the tube and ovary, which are plastered down on it. Covering almost the entire upper surface of the tumor is omentum, which is densely adherent to the mass and furnishes a large part of its blood supply. The walls of this tumor vary from the thickness of paper to two or three millimeters. From this tumor grumous material, like fat mixed with pus, escapes and at several points hair can be seen. On cutting a window out (Fig. 6) the interior is found to be filled with a fetus, which is of at least seven or eight months' growth. On account of the distorted condition it is difficult to get the exact age, but the sole of the foot measures 6.5 cm. in length and looks mature. The other parts are correspondingly large. The hair of the child is black and curly. There are several points where slight ulceration of the surface has taken place. These points correspond to the very thin areas noted in the outer covering. The right tube, which was so firmly glued down that it was thought necessary to remove it, in the hardened state, measures 10 cm. in length. It is entirely covered by adhesions, and at its fimbriated end reaches 2.5 cm. in diameter. The ovary is also covered by adhesions, but is not enlarged.

The left ovary is very much flattened and covered by adhesions. The tube runs over into the tumor mass and is lost. It is flattened out and at one point measures 8 cm. in diameter. The placenta is attached to the left side of the mass.

Histologic Examination.—The sac enclosing the fetus shows that where the omentum has been adherent it has been transformed almost entirely into new and old connective tissue, and the outer adhesions which contain islands of adipose tissue are for the most part made up of dense fibrous tissue. Passing inward the fibrous tissue looks older and then hyaline areas are seen which in size and form closely resemble placental villi. Between these are many small round cells and spindle cells. The inner portion is composed of similar hyaline areas surrounded by a zone of brown pigment that has evidently resulted from an old hemorrhage. The inner surface is lined by necrotic tissue which is especially rich in canalized fibrin, containing chiefly polymorphonuclear leucocytes. In no place is there evidence of muscle fibers and it looks as if the case was one of an abdominal pregnancy in which the sac, which was partly supported by the omentum, had gone on to new connective tissue formation.

Remarks.—As noted in the description of the operation the uterus was in no way implicated in this growth. It was situated in the center of the abdomen and gave no signs of being half of a bicornuate uterus.

Diagnosis.—Abdominal pregnancy of 4 years' standing, supuration of the sac, dense omental adhesions.

CHORIOEPITHELIOMA, WITH THE UTERUS THE SIZE OF THAT OF A FIVE MONTHS' PREGNANCY, HYSTERECTOMY, APPARENT RECOVERY

This disease, although by no means rare is not very common. From Baltimore only two cases have been reported. In 1895 J. Whitridge Williams,⁶ under the title "Deciduoma Malignum" reported a case occurring in the University of Maryland Hospital, and in the last edition of Kelly's "Operative Gynecology" a case is cited from the Gynecological Department of the Johns Hopkins Hospital. Thus at the Johns Hopkins Hospital only two cases have been encountered in 17 years.

By a fortunate coincidence on the morning on which I operated on the patient whose history is here given, Dr. Cuthbert Lockyer of London, England—the man who has worked so much on this subject in Great Britain—was present. Even from the macroscopic examination the gross appearance was so characteristic of the placental growth that both of us at once said "chorioepithelioma." In this case the decidual-like cells, those supposed to originate from Langhan's layer, predominated, but in some places the large sinuses, the brown-staining protoplasm and the characteristic vacuoles were in evidence. The specimen is particularly interesting on account of the uniformity of the distribution of the growth throughout the entire uterine body.

CASE 5, Gyn No. 13204.—The patient was admitted to the Johns Hopkins Hospital on Aug. 31, 1906, and was discharged on Sept. 25, 1906.

Examination.—She was not very well nourished. The mucous membranes were of a fairly good color. There was no glandular enlargement. The heart and lungs were normal. On examination Dr. Rushmore found the abdomen somewhat distended by a firm mass which rose out of the pelvis and extended as high as the umbilicus, rather more prominently on the left than on the right side. The mass was slightly movable and not tender except just above Poupart's ligament on the left side. It was regular in outline and on deep inspiration its upper border was obliterated by the surrounding intestines. The vaginal outlet was moderately relaxed, the cervix was high in the vaginal vault, lying far back and pointing downward. The cervical lips were not hypertrophied, the os was slightly patulous. There was no induration suggestive of new growth. The mass in the pelvis was uniformly fixed. On examination, under ether, the tumor seemed to be freely movable, but resembled a fibroid about 6 inches in diameter with a cystic mass on the left. The breasts contained colostrum.

Operation.—September 3. On exposure of the enlarged uterus the appearance suggested pregnancy very strongly. The vessels were much dilated. No definite nodules could be made out in the fundus, but on the posterior surface was a slight prominence, with a curious yellowish discoloration of the tissue beneath, and there were numerous dilated blood vessels suggestive of a malignant new growth. As a definite diagnosis could not be made from palpation we decided to incise the uterus over the prominence, at the same time carefully walling it off, so that there would be no danger of infection and the general cavity would be protected. On incision a vascular new growth was immediately seen. This had a spongy appearance and immediately suggested a malignant growth differing entirely from carcinoma and in no way resembling sarcoma. The incision was immediately closed with silk and the uterus removed. A vaginal drain was inserted in the lower angle of the abdominal wound in order to drain down to the peritoneum. The liver was carefully examined for metastases, but none could be detected.

Result.—The patient was examined on September 24 prior to her discharge. The abdominal incision was well healed, neither induration nor tenderness could be made out in the vaginal vault. Dr. Holland writing me on Oct. 29, 1906, says "I received a letter from her two days ago. She was able to be about the house, is cheerful and is gaining in strength. She still complains of pain in the right arm which developed when she was in the hospital."

Remarks.—In this case there was no positive history of a recent miscarriage although the possibility can not be excluded. The contour of the uterus on pelvic examination strongly suggested a myomatous uterus and with the abdomen opened it was impossible for one to exclude the possibility of pregnancy.

Description of the Tumor (Gyn and Path No. 10278).—The specimen consists of a greatly and uniformly enlarged uterus measuring 20 cm. in length, 13 cm. in breadth and 12 cm. in thickness. The anterior surface is smooth and glistening, the posterior is covered by many adhesions thin and fan like. Attached near the left cornu is a tag of omentum. On section the uterine cavity is found to be 15.5 cm. in length.

The uterine walls vary from 3 to 6 cm in thickness. The outer portion of the wall consists of muscle varying from 1 to 1.5 cm in thickness. Lining the entire uterine cavity is a spongy, porous growth. The uterine mucosa as such is not recognized, but is represented by hills and hollows. The projections into the cavity are dome-shaped and vary from 5 to 2 cm in depth. Here and there on the surface are cystlike depressions with narrowed bands of tissue stretching from side to side. There are also numerous cavernous spaces bridged over by bands of the growth. This growth involves the entire uterine wall, both anteriorly and posteriorly. The great thickening in the wall is due to the presence of the growth, which varies from 1 to 6 cm in thickness. At the fundus it extends almost to the peritoneal covering. The growth in no way resembles a carcinoma, nor is there any appearance suggestive of a sarcoma. One is instantly reminded of the growths that occasionally occur after a miscarriage. The cervix is somewhat flattened, is 6 cm in breadth, and its lips appear to be normal (Fig 7).

Microscopic Examination—Sections from the cervix show little alteration save for the fact that many of the glands are small and round, and that they appear to be somewhat dilated. Here and there they extend for some distance into the muscle. They do not, however, show the slightest evidence of any active process. The tissue lining the cavity has undergone almost complete necrosis. It is still represented, however, by a great deal of canalized fibrin containing polynuclear leucocytes, and here and there, especially in the vicinity of the large blood vessels, are areas where the cells are still preserved. These consist of large discrete cells containing small vesicular nuclei, nuclei of moderate size that have stained deeply, and still larger nuclei containing vacuoles and great masses of protoplasm staining very deeply. The protoplasm of many of the cells contains vacuoles or clear spaces. In the deeper portion, that is, in the vicinity of the muscle, there are large blood sinuses, and lining these are cells closely resembling decidual cells. They have for the most part vesicular nuclei, which vary considerably in size from very small ones to others very large and lobulated. Scattered throughout this decidual like tissue are numerous vacuoles. In the vicinity is much canalized fibrin with isolated cells of a smaller character scattered throughout it. The protoplasm of these so-called decidual cells, wherever situated, is of a brownish tinge. At numerous points are isolated masses of these decidual like cells lying perfectly free in the blood, thus showing that they are either isolated and free masses or finger like projections cut across. In some places are large plaques of protoplasm containing six or more nuclei, and in the immediate vicinity the canalized fibrin contains collections of polymorphonuclear leucocytes. At a few points are elongated, very deeply staining masses of chromatin lying free in hyaline material. The line of demarcation between the muscle and the new growth is at some points sharply defined, but in numerous places the cells of the new growth are wandering in and completely overwhelming the muscle fibers. In the advancing margins there is a certain amount of small rounded cell infiltration, and in the corresponding deeper portions there is a great tendency for the growth to undergo coagulation necrosis. This is undoubtedly a chorioepithelioma, but one in which no placenta villi are demonstrable.

Remarks—The contour and general form of this growth before the uterus was opened corresponded almost identically with those of a myomatous uterus. There was on the left side a slightly nodular elevation which was most suggestive of myoma. Curettings, of course, in this case would have yielded nothing but necrotic tissue, but this should immediately have put us on our guard. Such a finding would exclude myoma and would also tend to rule out adenocarcinoma, as in an adenocarcinoma such extensive areas of coagulated necrosis are rarely to be found.

Histologic Examination of Scrapings Four Months Before Admission to Hospital—These scrapings were made by Dr. Holland and fortunately had been put aside and were examined after the removal of the uterus. It will be seen that although there are a few suspicious changes no positive diagnosis could have been made.

Gyn and Path 10275. The greater part of the tissue is entirely necrotic, it takes the eosin stain, or when the hematoxylin is noted the cells are very cloudy. In some places there are shadows of very large nuclei and here and there the nuclei are still perfectly preserved. These, however, are elongated, some of them are irregular and stain deeply. The picture is not one that would enable a pathologist to make a satisfactory diagnosis. There are, however, islands that strongly suggest sarcoma or that, considered in conjunction with the history, suggest a malignant placental growth. The section is one that would certainly call for further examination.

THE PREFERABLE METHOD OF ANTERIOR FIXATION OF THE UTERUS WHEN THE ABDOMEN IS OPEN

H. S. CROSSEN, M.D.

ST. LOUIS

(Continued from page 1490)

affecting a decided change in the direction of traction. The operation has the disadvantage that it requires extensive dissection and handling of tissues deep in the abdominal wall.

Of the various methods of utilizing the round ligaments after the abdomen is open, the one I have found most useful is practically the Gilliam-Ferguson operation. Instead of following the usual technic however I find that the work can be more conveniently and expeditiously executed by passing a puncturing tenaculum forceps (Fig 1) through the wall, grasping the ligament directly and bringing it out along the forceps track. The exact technic preferred for the class of cases under consideration is shown in detail in the following steps:

1. The special work for which the abdominal cavity was opened having been completed, the left round ligament is grasped with an ordinary tenaculum forceps about $1\frac{1}{2}$ inches from the uterus. The right ligament is caught in a similar manner with another forceps and then any retractors that are in the way are removed from the abdominal wall. The grasping of the ligament of each side with the tenaculum forceps facilitates the subsequent manipulation of the ligaments, after the removal of the retractors which expose the pelvic cavity.

2. The point of the puncturing tenaculum forceps is entered in the left side of the wound just beneath the upper sheath of the rectus muscle and about one inch above the pubic bone. It is passed outward just beneath the sheath for an inch and then the point is directed downward and made to puncture the rectus muscle and posterior sheath, but not the peritoneum. Guided by the fingers in the abdomen, it is then passed outward between the peritoneum and the aponeurosis to a point about one inch from the internal inguinal ring, where it is made to penetrate the peritoneum. The handle of the instrument is then raised so as to direct the point toward the round ligament and is made to grasp the ligament and peritoneum $1\frac{1}{2}$ inches from the uterus (Fig 2).

In the class of cases under consideration the ligament and peritoneum are usually so stretched and lax that they are easily drawn into the new canal as a small cord. If the ligament is unusually thick or if the peritoneum is so thickened that it probably will not pass easily into the forceps canal a window may be snipped in the peritoneum in front of the ligament and the ligament alone grasped and brought into the canal.

3. The forceps is then withdrawn bringing the ligament with it into the forceps track and out at the ab-

dominal wound (Fig 3) The loop of ligament brought out is now caught and held by an ordinary tenaculum forceps, while the right ligament is brought out in a similar manner After the ligaments are brought into position the tension is adjusted. It may be necessary to bring out a little more of the proximal portion or a little more of the distal portion, the former to bring the fundus well forward and the latter to close effectively any space that may exist between the distal portion and the parietal peritoneum By paying attention to this latter point the peritoneal puncture may be made a considerable distance from the internal inguinal ring without leaving any opening through which an intestinal coil might slip If fearful on this point, the forceps may be carried to within half an inch of the ring or even practically to the ring before puncturing The peritoneum being freely movable on account of the loose subperitoneal tissue, is drawn inward and puckered when the proximal portion of the ligament is drawn on to bring the uterus forward This brings the peritoneal exit near the aponeurotic exit of the new ligament, near the outer margin of the rectus muscle The direction of the new ligament, therefore, is forward, practically the same as in the Gilliam-Ferguson operation by the regular technic

4 The ligaments are then fastened in their new position If long enough the loops are overlapped in the median line and fastened to each other and to the upper sheath of the rectus If not long enough to reach to the median line, they are fastened securely in the forceps track by catgut sutures passed through the upper sheath and the ligaments beneath The abdominal incision is then closed in the usual way

By the method just detailed, the ligaments may be transplanted into the abdominal wall very quickly—giving a strong, reliable forward and upward traction to the uterus and adnexa and without any free bands or dangerous adventitious openings The advantages of his particular technic in suitable cases over the usual technic of the Gilliam-Ferguson operation is that it simplifies and expedites the work by doing away with the temporary ligation of the ligament and also with the lateral puckering suture.

The puncturing tenaculum forceps here mentioned may be used with advantage in the regular Gilliam-Ferguson operation It may be used also in those operations in which the puncture of the aponeurotic wall is made practically at the internal inguinal ring, though care must be exercised that the deep epigastric vessels be not injured

I designed this puncturing tenaculum forceps some time ago and after considerable experimenting have about what I want I have been using it now for a year and have found it so convenient and satisfactory that I thought it worthy of presentation as a useful addition to our armamentarium.

I have used it both with the ordinary longitudinal incision and with the transverse incision It is strong and slender and is designed to pass easily through the tissues of the abdominal wall, to penetrate the aponeurosis and peritoneum at any desired point, to grasp the round ligament firmly without bruising it and to return through the wall, bringing the ligament along the new canal Possibly some one has already described such a forceps, if so, it has escaped my notice Both the Gilliam forceps and the Barrett forceps are radically different.

WHEN THE ROUND LIGAMENTS ARE FIXED

In this class come those cases of retrodisplacement in which there is fixation of the round ligament and adjacent tissues so that it is not practicable to draw into the wall either the round ligament and adjacent peritoneum or even the round ligament alone

Such fixation may be due to inflammatory infiltration, associated with salpingitis, peritonitis or cellulitis or it may be due to the way the ligatures are placed in removing a damaged tube or ovary Unless particular care is exercised in excising the damaged adnexa, the tissues are likely to be fixed by the ligatures, in fact, when mass ligatures are passed and tied before the uterus is brought well forward the organ may be so fixed by the ligatures that it can not afterward be brought forward satisfactorily To prevent this it is well to avoid mass ligatures and to bring the uterus well forward before tying any ligatures that may interfere with its mobility

In these cases the round ligaments are so fixed by inflammatory infiltration or other abnormal condition that the lateral implantation operation can not be satisfactorily carried out In these cases the choice lies between ventrosuspension and the regular Gilliam-Ferguson operation with very short ligament loops The latter, I think, is the preferable operation of the two, for the reason that the suspension cords are stronger and more enduring and there is no free band in the peritoneal cavity with which the intestines may become entangled Also the lateral sutures may be passed so as still better to elevate the prolapsed adnexa Furthermore, there is little or no chance of a firm fixation by scar tissue that would interfere with pregnancy

In the execution of the regular Gilliam-Ferguson operation, the puncturing tenaculum forceps is exceedingly convenient for puncturing the rectus muscle catching the ligament at the desired point (Fig 4) and bringing it out through the muscle A short one, only slightly curved, would be more convenient in this particular operation, though the long one may be used

In the class of cases under consideration, it is seldom that the broad ligament tissue is so infiltrated that the round ligament can not be brought out the short distance required for this operation In such an extreme case, regular ventrosuspension would be required

Fastening the uterus forward by attaching the fundus to the vesical peritoneum seems hardly sufficient for the necessities of the case In nearly all cases of troublesome backward displacement there is also considerable downward displacement which has an important bearing on the patient's distress Any operation carried out for the retrodisplacement should overcome also the prolapse of the uterus and adnexa The uterus should be held up as well as forward, and ordinarily this can not be accomplished satisfactorily by simply bringing the fundus forward and fastening it to the vesical peritoneum

WHEN THE CERVIX IS TOO FAR FORWARD

In the cases of this class the cervix comes so far forward that the uterus does not have the proper forward inclination even when the fundus is brought well into the front part of the pelvis The raising of the fundus and the adnexa relieves the symptoms for a time, but the position of the uterus with the body still directed straight up or slightly backward is such that the intestines run in front of it and sooner or later it is forced backward again into a troublesome retrodisplacement

The cause of the cervix being so far forward is the lax condition of the supporting structures, particularly the

sacrouterine ligaments. Occasionally the cervix is held forward by shortening of the tissues anterior to the cervix from inflammation or other cause. When this is the case the contraction should be overcome by stretching or incision before an attempt is made to fasten the uterus forward. Generally, however, the tissues are lax all around the cervix.

In these cases, in addition to fastening the fundus forward while the abdomen is open, the cervix should be drawn backward and raised by shortening the sacro-uterine ligaments. This is accomplished by means of a puckering suture. Bovee has probably done more in the development of round ligament shortening by various methods than any one else.

We are interested now only in the shortening when the abdomen is open. With good exposure of the pelvic cavity and the intestines packed out of the way there is not much difficulty in accurately placing a suture that, when tied, will effectually pucker the ligament and lift the cervix upward and backward. As Dr. E. C. Dudley has pointed out, the suture should be passed rather superficially so as to avoid injuring vessels and other structures near the pelvic wall, and the surfaces to be brought together should be roughened so that agglutination will take place and adhesions follow. Both sutures could be placed before adhesions are tied, for when the cervix is drawn back close to the rectum it is difficult to place a suture satisfactorily in this region.

In most of these cases of relaxed sacrouterine ligaments there has been marked laceration of the pelvic floor, the repair of which is indicated as a part of the operative work. Occasionally, however, such a condition of the sacrouterine ligaments is found in patients who have borne no children and have no laceration of the pelvic floor.

In cases with laceration, repair of the pelvic floor for the purpose of holding the cervix well back in the pelvis sometimes proves insufficient, the constant pressure of the unsupported cervix causing gradual stretching of the repaired floor and finally descent of the cervix to its old position and a return of the retrodisplacement. In these cases, shortening of the sacrouterine ligaments while the abdomen is open, in addition to fastening the fundus forward, adds much to the completeness and permanency of the replacement and may make the difference between success and failure in the final result.

WHEN THERE IS CONTRACTION OF THE POSTERIOR PART OF THE BROAD LIGAMENT

There are certain cases of retrodisplacement with extensive chronic inflammation in which, after removing a disorganized tube and breaking up the adhesions posterior to the uterus and broad ligaments, there is still so much inflammatory infiltration limiting the mobility of the uterus that it can not be brought well forward without danger of injury to important structures or such resulting tension as will cause distress. The question is: What is the best procedure in such a case? Shall we persist in trying to loosen the uterus so that it will come far forward, at the risk of an injury to the large vessels along the pelvic brim which are firmly imbedded in the infiltrated tissue, shall we fasten the fundus forward to the abdominal wall under strong tension, or shall we leave it in its perpendicular or slightly backward position?

I think that as a rule, the last-mentioned plan is the best in these exceptional cases. The principal symptoms are due to the inflammatory mass which has been re-

moved. Usually the uterus can easily be brought forward to a position midway between the normal position and decided retrodisplacement, and this position, when maintained, practically never in itself causes troublesome symptoms.

Whether the uterus will stay in this elevated position or return to its former one depends on whether the tissues are pliable and the uterus movable. If they are, the uterus will not stay in this midposition, but when the tissues are fixed by infiltration, this with the scar tissue that results from the removal of the diseased tube or tubes so fixes the uterus that it is likely to be held in that position indefinitely.

To favor the maintenance of the uterus in this position, care should be taken, before closing the abdomen to see that the intestines extend into the posterior part of the pelvis and that the omentum comes down over them and is, when long enough, tucked in back of the uterus. The intestines and omentum back of the uterus assist in holding the latter forward during the healing process and also tend to prevent adhesions which extend directly from the uterus to the posterior pelvic wall, the contraction of which would draw the uterus further back.

In certain of these cases some of the structures alongside of the uterus on one or both sides may be fastened forward, thus helping to maintain the uterus part way forward both during the healing process and afterward. In one especially troublesome case of this kind I was able to secure a satisfactory result by suturing the upper anterior margin of the broad ligament to the anterior abdominal wall for a considerable distance inward from the pelvic margin on each side.

In the after-treatment of the cases of this class, it is well to have the patient lie on her side and well forward partially on the abdomen, most of the time, and not much on her back. If the cervix comes low, it is well also to have the patient wear a pessary that will hold it well back in the pelvis during the healing process, provided the instrument causes no severe pain.

TREATMENT OF TRAUMATIC GANGRENE

VAN BUREN KNOTT, M.D.
SIoux CITY, IOWA

In this brief paper it is my intention again to call attention to a procedure which in my experience has proved of great utility in the management of these most troublesome and often fatal cases. I shall not take up the pathology of traumatic gangrene, but shall confine myself to a consideration of its treatment. By the term traumatic gangrene as herein used is to be understood that variety of gangrene following severe crushing injuries of the extremities complicated by virulent and often rapidly fatal sepsis.

On referring to the literature we find all authorities agree as to the extremely high mortality of this affection. Cheyne and Burghard giving it as high as 95 per cent. All authorities likewise agree that the only treatment of cases of this class is early amputation above the gangrenous area.

How often are we able to determine accurately the limits of the disease particularly in those cases of rapidly spreading moist gangrene? Too often we are disappointed by the continuation of the process after amputation and are compelled to reamputate many times in spite of which the patient often

If the gangrenous process does not involve the entire limb the flaps frequently slough, necessitating another operation and the sacrifice of what is too often most valuable tissue so far as the future usefulness of the part is concerned. In other cases I have been convinced by subsequent events that in my effort to get well above the disease I have sacrificed tissue which might have been saved. In other words, I have amputated at a point higher than was necessary.

In casting about for the probable cause of the unsatisfactory course pursued by many of these cases, I became convinced that it was the attempt to form flaps from tissue, the vitality of which is always seriously in question, and the further impairment of that vitality by two procedures necessary to this method of operation: first, the dissection of the flaps, second, the introduction of sutures.

The dissection of the soft parts into suitable flaps necessarily interferes with their blood supply, which interference in the class of cases under consideration is often badly borne and frequently resented by sloughing of the flaps or the rapid extension of the gangrenous process up the limb. The introduction of sutures at this time has two distinct disadvantages: first, the retention within the wound of infectious elements which may have traveled up between the muscle planes or along tendon sheaths to a point higher than we may believe probable, second, the further interference with flap nutrition by the tension of the suture, for tension can not be entirely avoided, no matter how carefully the sutures may be placed. Believing the statements above made to be true, and that the bearing of these facts on the results secured in these cases was most important, in 1902 I described a method of amputation which had, in my hands, greatly reduced the mortality of traumatic gangrene. Since then I have had several opportunities to demonstrate further the value of the method.

The procedure is as follows: Being confronted with a case of traumatic gangrene of an extremity, estimate as exactly as possible the line between the diseased and healthy soft parts. Under anesthesia make a most careful and complete disinfection and cleansing of the skin, puncturing all bullæ and remove all discharges, envelop the gangrenous area in a sterile towel up to the line selected and then, at this point, make a circular amputation, cutting through soft tissues and bone at the same level. Ligate carefully all bleeding points, including none of the perivascular tissue in the bite of either the forceps or the ligature. Leave the wound open, not introducing a single suture, and apply moist dressings of gauze saturated with salt solution, these dressings to be changed from two to four times in twenty-four hours, as the circumstances of the particular case demand.

After seven to ten days, if the wound is perfectly clean and the condition of the patient favorable the classic circular amputation may be made by dissecting up the flap already outlined and sawing the bone at the proper level. If for any reason the circular method may seem undesirable, any other procedure may be substituted, but in the class of cases under discussion a typical circular amputation will be found entirely satisfactory.

It is unnecessary to report in detail the cases treated by this method, but it may be stated that since adopting it in 1900 I have employed it nine times: twice in amputations in the subtrochanteric area, twice in the middle third of the thigh, four times in the upper third of the leg, and once in the forearm. The results were eight recoveries and one death.

The two cases of subtrochanteric amputation will be briefly described as they presented all the difficulties common to the most severe and fatal types of traumatic gangrene.

CASE 1—A boy, aged 12, was run over by a disc harrow and the left leg frightfully mangled to condyles of femur. Brought to hospital by Dr. Evans of Emerson, Neb., on the third day after the accident, at which time gangrene had reached the lower third of the thigh and presented the usual clinical features of traumatic gangrene. The patient was delirious, having a temperature of 104 F and a pulse of 130. Amputation as above described was made immediately at a point just below the great trochanter. Pulse and temperature reached normal within forty-eight hours, delirium had disappeared and the wound appeared clean. On the tenth day after the injury tetanus appeared and for four days death was hourly expected. Following the usual treatment, complete recovery from tetanus occurred, and two weeks later the flaps were dissected up, the head of the bone disarticulated and good union was secured. Since this time the patient has been well.

CASE 2—J. M., man, aged 40, fell under a slowly moving train and sustained a severe crushing injury of the right foot and ankle. He was brought to the hospital thirty-six hours later by Dr. Langley of Orcoma, S. Dak. At this time gangrene had extended to the malleoli and the patient's condition was good. Not realizing the gravity of the case and thinking that, owing to almost total absence of constitutional symptoms, the case was one of ordinary gangrene due to thrombosis, I made a classical amputation just below the knee. Twenty-four hours later pulse was 110 and temperature 102 F. The flaps looked suspicious. Thirty-six hours later the pulse was 158, temperature 105.5 F, and the patient in a low muttering delirium. There was gangrene of the flaps and discoloration to the middle third of the thigh. Realizing that prompt separation from the gangrenous and infected leg gave the only chance of life, I decided to reamputate.

The patient's condition would not permit use of general anesthesia and, owing to the condition of the limb, local anesthesia was considered inadvisable. With no anesthesia what ever amputation through bone and soft tissues as described was rapidly made slightly below trochanter. Owing to advanced sepsis the senses of the patient were so obtunded that he gave no evidence of pain except at the moment the knife severed the sciatic nerve. Despite the fact that we expected this man to die on the table or soon after, he began to manifest improvement a few hours after the operation. In twenty-four hours his pulse was 120 and temperature 101 F. Forty-eight hours later pulse and temperature became normal and so remained. Twelve days later, the wound being clean, flaps were dissected up and the bone sawed through at the trochanter and the wound closed. Primary union was secured, stitches were removed on the eighth day and the patient was up and about the ward on crutches. Was told one day that he might leave the next morning for home and that night died suddenly of pulmonary embolism.

The stump was absolutely clear and union perfect. This was the most desperately sick patient I have ever seen recover from gangrene and one on whom I could not think of operating by any other method. His tragic death after apparently complete recovery was particularly unfortunate and should not be charged against this particular plan of operation, as it might have followed any operation.

As my results by the old method can not be compared with those secured by this, I have ventured to present the operation for consideration. Its advantages may be summarized as follows:

1. By it we may speedily and with the minimum of shock remove from an enfeebled and exhausted patient the source of infection, namely, the gangrenous tissue.

2. We may frequently make the amputation at a lower point than would be possible by the old method, because

soft tissues whose vascular connections are left undisturbed are less apt to slough

3 The freest possible drainage is provided for a sufficiently long time

4 If the disease stops at the line first chosen, no unnecessary sacrifice of tissue has been made, as the flaps have been defined at the lowest limit of safety, and the bone would necessarily have to be sawn at the same point as at the second operation

5 If the limits of the disease have not been placed sufficiently high, the same procedure may be repeated with less danger to the patient than a typical reamputation

6 Patients too weak and prostrated by sepsis to withstand a typical amputation may endure this much shorter procedure and be built up during the interval before the second operation is necessary

IS EYESTRAIN EVER AN ETIOLOGIC FACTOR IN EPILEPSY?*

H O REIK M.D.

Associate in Ophthalmology and Otology in the Johns Hopkins
University
BALTIMORE

In reporting the following four cases of epilepsy in which the active causative agent appears to have been eyestrain and in which correction of the refraction errors relieved the greater affection, I am actuated by a desire to aid in promoting the educational work that other ophthalmologists have been doing in this direction, and possibly to benefit some other sufferers, rather than to enter into the dispute regarding the relationship of eyestrain to epilepsy. My own observations convince me that an epileptic seizure may be induced by reflex action from an ocular disease. There may be some physicians who do not want to be convinced of this, there are certainly some who deny the possibility of the eyes playing any important part in connection with epilepsy, and the great mass of the profession has probably never given any consideration to the matter and would have no answer prepared for the question expressed in the title of this paper.

The primary reason for stating the question is that it may serve as the basis for a dispassionate consideration of the subject, for it is an important matter that the proper answer should be determined and, if it be in the affirmative, as many of us believe it will be, it is equally important that the general profession should be so informed and should apply that knowledge for the prevention or alleviation of human suffering. It has been estimated that there is one epileptic in every 500 inhabitants in this country, applying that to the city of Baltimore, let us say, would mean that we have nearly 1,200 victims of epilepsy, or furthermore about 2,000 in the state of Maryland. Surely it is worth while to give serious consideration to any disease that afflicts so many citizens in a community. Another most excellent reason for investigating any agency that might, even remotely, contribute as a causative factor is found in the fact that when once it is firmly established this disease has a bad prognosis. The percentage of patients cured by any or all forms of treatment is extremely small; the reports of some institutions in which epileptics are treated would seem to indicate that less than 1 per cent

are ever restored to health. The saving of an individual, then, from the development of epilepsy or the cure of one in whom the disease had started is like snatching a brand from the burning! If only one case in 100 is found to be due to eye disease and curable by the proper treatment of that organ, it becomes possible to double the present percentage of cures.

Whenever one reports the cure of a series of cases of some disease which is admitted to have a grave prognosis and in which the percentage of cures by any treatment is exceedingly small, he may expect skepticism on the part of his hearers and perhaps some doubt as to his diagnoses. While the diagnosis in my cases was vouched for by others, I have taken pleasure in fortifying my knowledge of the disease by a recent careful reading of the latest authoritative publication on the subject, *i. e.*, *Epilepsy and Its Treatment*, by William P. Spratling, superintendent of the Craig Colony for Epileptics, published in 1904.

I may be pardoned for quoting extensively from this book, for Dr. Spratling does not advocate the idea that eyestrain bears any relation to epilepsy, and probably did not dream that his book would ever be used to support such a theory. I believe, however, that he submits the best of evidence in support of that theory, and that his opposition to the theory in other writings, as well as in his book, is not only unjustified by, but is in defiance of his own observations.

What is the etiology and pathology of epilepsy? Regarding its etiology, Dr. Spratling says (page 58)

We may assemble the causes of all epilepsies primarily under two heads: Predisposing and Exciting. Under the former will be studied the comparatively few factors that prepare the individual to acquire the disease, but which may not actually produce it, under the latter, as many as possible of the numerous factors that actually produce epilepsy with or without the aid of influences that predispose to it.

In the majority of cases predisposing and exciting causes play a part and are complementary to each other. This well known fact we may illustrate in this way: Given an individual in whom epilepsy may be induced under the influence of some irritation of which the climax—*i. e.*, the point at which it causes the seizure to appear—is represented by 100. If there are already present 60 of these points from, we will say, a predisposition due to heredity, there will remain but 40 points to be supplied by some exciting cause to bring the disease to light, this exciting cause being, perhaps one of the specific fevers, some kind of toxemia, an emotional shock, an acute attack of indigestion, trauma, some reflex irritation or numerous other causes which will be fully described later on. In other words, epilepsy etiologically considered is often a symptom complex dependent in the great majority of cases on two variables, either a maximum of inherited influence combined with a minimum of exciting cause, or a minimum of inherited influence combined with a maximum of exciting cause.

No one will question the importance of an hereditary predisposition in many cases, especially in those cases of direct hereditary transmission of epilepsy or in which the child acquired its predisposition from a parent who had some other nervous disease, such as alcoholism or insanity. The exciting causes are the ones bearing particularly on our question and I would call attention to the list mentioned in the above statement regarding etiology. It will be noticed that with the exception of toxemia and trauma all of the exciting causes named must act reflexly. Just what that process of reflex action may be is not positively known but it would seem most plausible to assume that through the abnormal action of certain organs toxins may be introduced and thus injure the delicate structure.

* Read at the meeting of the Section on Clinical Medicine and Surgery, Baltimore City Medical Society, Dec. 7, 1906.

tex when brought into contact with them The same author says on pages 326 and 328

The essential poison in epilepsy is a nuclear poison which shows a special predilection for certain delicately constituted cells of the cerebral cortex, typical of the second layer

The majority of good observers in chemical pathology believe that the blood, sweat, urine and gastric contents are hypotonic in the interparoxysmal state of epilepsy, hypertonic just before a fit, at the time of and for a variable period just after the fit

Whether the chemical substance, which, by its poisonous effect on the cerebral cortex produces epilepsy, be carbonate of ammonium or cholin or xanthin or some undetermined autocytotoxin, is of no consequence to us at the present moment. What is of some importance, and seems to be known definitely, is that in certain persons predisposed to the disease any agency which can induce the formation, or liberation, into the circulation, of the necessary poisonous substance in sufficient quantity to cause an epileptic explosion, by its action on the brain cells, may properly be called an exciting cause of epilepsy That the formation or liberation of such poisonous substances may be caused by reflex action is set forth by Dr Spratling in the above-quoted statement concerning the etiology of epilepsy and supported by numerous cases related in his book. The list of reflex exciting causes given there (pages 75-122) are dentition, emotional shock, prolonged anxiety, grief or overwork, gastrointestinal disorders, disorders of menstruation either functional or organic, the menopause and pregnancy, masturbation and stricture of the urethra Nasal and ocular diseases are mentioned as having been claimed by some writers as the cause of epileptic attacks in some instances, but he has not seen any cases due to abnormal nasal conditions, and concerning eyestrain, says

I am unable to recall a case of epilepsy in all of my experience in which I felt that defective ocular conditions alone caused the disease

Let us consider some of the above-named admitted excitants which may properly be compared with nasal or ocular affections as reflex causative factors in epilepsy

Dentition—Dr Spratling says of this

It has long been my belief that dentition when severe, and acting on an organism that bears the impress of transmitted weakness of a necessary kind, plays an important rôle in the production of epilepsy in early life

This view is supported by such eminent neurologists as Gowers, Feré, Hammond, Peterson, Clouston and Voisin Surely one would be justified in asking, if dentition, why not eyestrain?

Gastrointestinal Disturbances—Under this heading Dr Spratling says (page 110)

The epilepsies due to derangements of this part of the nutritional system are, in my opinion, of greater importance than they are generally supposed to be By gastrointestinal disorders I do not mean so much to include diseases of the alimentary tract, like chronic diarrhea and ulcers of the stomach as I do acute indigestion and intestinal toxemias Irrespective of the absorption of poisonous matter into the blood from the alimentary canal, the irritation of the peripheral nerves (visceral) in this locality may alone cause reflex convulsive phenomena that may persist as epilepsy

Now, if irritation of the peripheral nerves of an organ like the stomach can produce epileptic attacks, why may not irritation of the ciliary nerves of the eye? It can hardly be claimed that the nerves supplying the muscles

of the eyes, intraocular and extraocular, are not as constantly employed or as much abused as those of the stomach The eye muscles, the ciliary muscles particularly, are working every waking moment of the individual's life, what an opportunity for irritation when there is an optical defect that must be constantly compensated for by muscle action in excess of that the eye was by Nature designed to endure

Disorders of Menstruation, Onset of Menopause, Pregnancy—The same author is responsible for the assertion that either functional or organic disorders of menstruation may be causative factors in epilepsy, and that occasionally the menopause, pregnancy or maternity marks the onset of epileptic attacks

The pathologic conditions within the abdomen, which may be a factor in causing or increasing the frequency of epileptic seizures, are generally those affecting the ovaries and uterus, the condition having persisted a sufficient length of time to set up reflex nervous symptoms Anterior and posterior displacements of the uterus with the ovaries and tubes bound down by firm adhesions, also constitute conditions productive of reflex symptoms in various parts of the body and may act unfavorably on the patient's epilepsy

I have no doubt whatever of the correctness of all this, but physicians who, by daily experience, are familiar with the serious reflex consequences of eyestrain, such as severe headaches, nausea, vomiting and vertigo, must smile at the notion that slight ovario-peritoneal adhesions or urethral strictures can produce more serious effects on the cerebrospinal system than it is possible for eyestrain to do

Emotional Shock—No less an authority than Gowers attributes epilepsy to shock in many instances and says "Of all the immediate causes of epilepsy the most potent are psychic—fright, excitement and anxiety" Now, it seems to me, that if we admit all the other reflex disturbing agents, as exciting causes in epilepsy, it is perfectly ridiculous to argue against the possibility of eyestrain or nasal irritation assuming the same pathologic rôle No one can read Dr Spratling's report of the investigations made at Craig Colony by Drs Gould and Bennett, and his disputes with Dr Gould thereafter, without being convinced of his unfairness in the matter His own figures do not bear out his conclusions and his prejudice is most strikingly shown in his refusal to consider glasses of curative value in a case which, according to his own statement, had no epileptic attacks during a period of fifteen months after beginning the use of correcting glasses and suffered a recurrence only after those glasses had been broken It is noteworthy that in his book he says of eyestrain, that he has not seen a case in which he felt that "defective ocular conditions alone caused epilepsy" If he means by that to eliminate the predisposing factor, he is begging the question, for it has not been claimed that eyestrain or any other reflex would cause epilepsy in an individual not possessed of that weakened nervous system which predisposes to the disease If he meant, as a casual reader of that sentence is justified in inferring, that eyestrain never produces epilepsy even in a person predisposed to the disease, he is certainly wrong A host of competent observers, mostly ophthalmologists, have now reported cases of epilepsy cured by treatment of the eyes, either by the wearing of glasses or by the operative correction of abnormalities or defects of the eye muscles When such reliable and conservative observers as Drs Samuel Theobald, Myles Standish and Wendell Reber endorse the theory, or report cases of the kind observed, we can not put the question aside as hobby-riding

Dr Theobald very kindly permits me to relate here a case observed in his private practice several years ago. In February, 1889, a man 37 years of age, suffering with epilepsy, consulted him because of poor vision and asthenopic symptoms. The following glasses were prescribed for constant wear. Right eye, $+3.50$ Ds $= +50$ Dc Ax. 180, left eye, $+3.50$ Ds $= +62$ Dc Ax 180, which gave perfect vision and normal muscle balance. The patient had been subject to epileptic seizures every three or four weeks and lost at least two days a month from his work. In August, 1900, he reported that the epilepsy had been greatly improved since securing the glasses, but that recently the eyes had again become weak and he had suffered a recurrent attack. Examination disclosed the necessity for a change in the lenses and in November of the same year he reported a comfortable condition, with only slight nervousness and but one-half day's loss of work in four months.

My own clinical experience is as follows:

CASE 1—Miss E. M. A., of Wheeling, W. Va., aged 18, consulted me at the Johns Hopkins Hospital dispensary in July, 1899. She had been under observation in the neurologic department of the same hospital for some weeks and Dr. Thomas, who made the diagnosis of epilepsy, referred the patient to me for an aural examination because of the peculiar aura in the case. She gave the history of having had epileptic attacks at frequent intervals for seven or eight years. The attacks occurred generally in the night or early morning and were repeated from two to four times a month. She awoke with a scream, threw her hands to her ears, attempted to run, and fell unconscious. The seizure was typical of epilepsy inasmuch as she emitted the peculiar cry, frothed at the mouth during the attack, usually bit her tongue and passed from the attack into a deep sleep. On the following day she was usually very weak and suffered a more or less severe headache. The preceding aura consisted in hearing musical sounds and, at times, she complained of tinnitus aurium between the attacks. An aural examination failed to disclose anything abnormal about the ears either in structure or function. During the examination she made some remark which caused me to suspect an abnormal condition of the eyes, and without any idea that this bore any relation to the epileptic condition, and with the notion solely of doing something to make her a trifle more comfortable, I prescribed a mydriatic and instituted a careful examination of her refraction. As a result of this the following glasses were prescribed: Right eye, $+2.50$ Ds $= +1$ Dc Ax. 120, left eye, $+2.50$ Ds $= +1$ Dc Ax. 60. The patient was advised to remain in the city in order that Dr. Thomas might have the opportunity of studying her condition, but as she suffered no epileptic seizures during the next two months she was permitted to return to her home. I saw her about one year ago and have recently heard from her through a sister who was passing through Baltimore. Only once in these seven years has she had an epileptic attack, and that occurred at a time when she sent her glasses to Baltimore for repairs and was kept without them for a week.

CASE 2—W. M., aged 20, referred to me by Dr. W. T. Watson on April 12, 1902. His family history presents the following points of interest in connection with his trouble, his mother is a nervous woman, although subject to no particular affections, a brother has suffered from epileptic seizures at irregular periods. Both of these boys had disliked school life, probably finding study painful, but their eyes had never been examined. The patient stated that since 10 years of age he had found it impossible to read or write, especially at night, without great discomfort. He had adopted a trade which required pretty close application during the day and secured some recreation in the evening by attending a gymnasium, where he was fond of exercising with the punching bag, a form of exercise requiring steady and active employment of the eyes. About one week prior to his visit to my office after a hard day's work and an unusually prolonged sojourn with the punching bag he arrived home feeling rather tired, and

was shortly afterward seized by an epileptiform attack. His physician, who lived but a few doors away and answered his call promptly, described this to me as of typical epileptic character. An examination under a mydriatic disclosed the existence of 450 diopters of hypermetropia in each eye, no astigmatism could be determined either by ophthalmometer or skiascopy and glasses ($+4$ Ds) were prescribed for constant wear. I heard nothing more of this young man, except that he had gone west, until this summer, when he came to my office to report that he had never suffered any recurrence of the epileptic attack nor headaches, but that on several occasions when his glasses had been broken, while awaiting their repair he had been more nervous than usual and at such times could not read with comfort.

CASE 3—Miss E. C., of Spencer, W. Va., aged 20, consulted me Dec. 19, 1905, at the instance of her brother, a physician, who knew Miss A., the patient referred to in Case 1. She had been a victim of headaches as long as she could remember, and abandoned school work at the age of 10 years. Any effort to study or perform close work of any kind rendered her very miserable. Menstruation appeared at the age of 12 years, and shortly after that she began to have epileptic attacks. These attacks continued, occurring always during sleep, and having the character of true epilepsy, she emitted the peculiar cry, developed spasms, became unconscious, frothed at the mouth, bit her tongue, and relapsed into slumber. She would be very weak the next day and suffer intense headache. As a general rule, these attacks occurred during the week preceding or the week following her menstrual periods, but her periods were irregular and the number of attacks varied, averaging, however, more than two a month. Examination of the eyes under a mydriatic gave the following result: Right eye, $+2.50$ Ds $= +50$ Dc Ax. 90, left eye, $+1$ Ds $= +1$ Dc Ax. 90. A full correction was prescribed on December 21 and on March 20, 1906, I received a letter from her in which she says, "I did not think it necessary to write sooner as I have felt so very well since I left Baltimore. My eyes have given me very little trouble since I saw you and I have had but one very slight nervous spell, during which I was not affected as usual but had only slight muscular twitchings, followed by headache for a few hours."

CASE 4—Miss N. B., of Henderson, N. C., aged 10, examined March 20, 1905, at the request of Mrs. H., a sister of the patient in Case 1. She was a delicate looking girl, but with no history of hereditary disease of any kind. Her mother, who accompanied her, appeared to be of a nervous temperament and a female cousin, daughter of the mother's sister, was reported to be subject to "nervous spells" without convulsions. Miss B. had been subject to headaches all her life, aggravated by any form of close work and particularly troublesome during the period of school life. The privilege of reading or sewing was denied her because of the knowledge that sick headache would surely follow such employment, though she had never been informed that her eyes were possibly associated with this disability. For five years she had been having "nervous attacks." These began with slight emotional and muscular disturbances. In the earlier ones the face showed rapid emotional changes and the twitching of the facial muscles was followed by general restlessness, moving the arms aimlessly or walking about the room hastily, during which time she seemed to stare into vacancy. She did not completely lose consciousness at such times. The attacks became gradually more severe and more frequent during the following year, having occasionally as many as eight a day, at the end of which period the first typical *grand mal* epileptic convulsion occurred. Occurring always at night these epileptic seizures recurred with varying frequency, but always more than once a month, for four years. The convulsion was invariably preceded by a shriek and accompanied by frothing at the mouth and biting of the tongue. On the following day she usually suffered from intense headache accompanied by nausea.

Inasmuch as the beginning of the nervous spells was coincident with the appearance of menstruation it was thought by the family that her troubles might be of a gynecologic nature but three capable physicians had examined her at different times and agreed

ing wrong in that region. Treatment by her family physician not proving beneficial, she was induced by the advertisements in a religious paper to try "Mrs. Converse's treatment," and for two years she had regularly taken this concoction, probably an expensive solution of potassium bromid. Making it clear to the mother that I made no pretense of ability to cure epilepsy, I informed her that, from the history of headaches I considered it important to have the eyes carefully examined and held out in justification of this the hope of greater comfort in life even if epilepsy was not affected by eye treatment. A mydriatic was ordered, and on examination by skiascopy the following result was obtained: Right eye, $+ 50$ Ds $= + 50$ Dc. Ax. 45, left eye, $+ 50$ Ds $= + 50$ Dc. Ax. 135. An esophoria of 1 degree at infinity and 4 degrees at reading distance was converted into orthophoria by glasses giving a full correction, and with this vision equalled $20/15$. I prescribed the above glasses for constant wear and told them that I believed the headaches would be relieved and that she would probably be able to read and sew with comfort, but that I could not encourage them greatly to hope for a cessation of the epileptic attacks, I was skeptical on account of the low degree of refractive error.

On May 21, 1906, this patient entered my office, and with much pleasure observed that I did not recognize her. The change in her appearance was certainly very marked, and any one might have been excused for not recalling the delicate patient I had first seen. She had been on a visit to New York and had stopped on her way home to tell me that she was perfectly well. Since she began wearing the glasses she has never had any recurrence of the headaches nor convulsions.

When I presented a part of this paper at a recent meeting of the Ophthalmologic Section of the Baltimore City Medical Society, Dr. J. Frank Crouch, in discussing the subject, related two interesting cases of his own experience, the notes of which he has kindly handed me with permission to publish herewith.

CASE 5—Clara K., aged 13, referred by Dr. G. J. Preston in April, 1905. The child for two years had been having severe chorea, for which all ordinary methods of treatment had been tried before she was taken to a specialist on diseases of the nervous system. On their first visit, Dr. Preston informed the parents that he was going to have all her organs examined in turn to try to find some causal factor, and advised them to consult an oculist first. Under atropin I found a hypermetropia of 3.5 diopters in each eye, for which full correction was ordered. The child began to improve at once, and at the end of three weeks was entirely free from choreic manifestations. I kept her under observation for six months and saw no tendency to recurrence.

CASE 6—Mrs. Emma Z., seamstress, was sent to me Nov. 2, 1898, by her physician, on account of severe headaches which occurred whenever any effort was made to use her eyes. Under a mydriatic the following defect was discovered and correction ordered: Right eye, $+ 1.25$ Dc. Ax. 105, left eye, $+ 3$ Ds. which glasses gave her 20/20 in the right and 20/30 in the left eye. After the mydriatic wore off a test of the muscular balance indicated an exophoria of 4 degrees for distance, which was increased to 8 degrees for near. The correction was worn for three months, at the end of which period a tenotomy of the external rectus of the left eye was performed, reducing the exophoria for near work to 1 degree. After the tenotomy the patient became entirely comfortable, using her eyes without pain the entire day.

"One month after operating she incidentally mentioned the fact that on account of her agitation she had forgotten to take a certain medicine which her physician had been giving to her because of fainting spells, and asked whether the operation could have any influence on her nerves, for she had had no recurrence since discontinuing her drugs, a thing which had not been possible for two years. I at once called up her physician, Dr. Wilmer Brinton, to learn the character of the attacks. To my inquiries he replied that the woman undoubtedly had epilepsy, having required large doses of bromids for more than two years. I kept close watch of this patient, making her re-

port at frequent intervals, and at the end of two years, inasmuch as she had no recurrence of epilepsy, dismissed her."

It seems to me that such cases as the six here reported tend to prove that eyestrain is an exciting cause of epilepsy in persons whose constitutional weakness predisposes them to the disease. The removal of one reflex excitant does not, of course, cure the disease, the predisposition is always there, and if the patient be again subjected to eyestrain the attacks will probably recur, or, if the eyes be kept in perfect condition, some other exciting factor, like pregnancy, shock or great anxiety, may precipitate a convulsion. Every case of epilepsy certainly deserves a careful examination of all the special organs, the eyes included, by experts for the purpose of ascertaining and eliminating any possible exciting factor.

Clinical Notes

REPORT OF A CASE OF REMOVAL OF THE GANGLION OF THE FIFTH NERVE FOR TIC DOULOUREUX

FOLLOWED BY PARALYSIS OF THE SEVENTH NERVE ON THE SAME SIDE

MILES F. PORTER, A.M., M.D.

Surgeon to Hope Hospital, Professor of Surgery in the Medical Department of Purdue University
FORT WAYNE, IND.

All cases of excision of the ganglion of the fifth nerve should be reported because of the comparative rarity of the operation, but an additional interest attaches itself to the case here reported because of the motor paralysis which followed.

History—F. P., male, aged 32, had little of note in his personal or family history, except that his father was an alcoholic. The patient lived for a time in Arkansas, but had to move on account of malaria. He was unable to take quinin for this disease, as the drug produced a severe hematuria. He commenced having attacks of pain in the spring of 1889. For these attacks he was treated medicinally and without relief. He also had most of his teeth extracted without, of course, any good resulting therefrom. In 1904 the superior maxillary branch of the fifth nerve was excised, the operation gave him relief for a few months, but the pain returned in the latter part of the same year, when the superior maxillary branch was resected for the second time. These operations were done by Dr. Ross at the Deaconess' Hospital in Indianapolis. The last operation gave relief for a short time only.

Operation and Result—On Jan. 28, 1905, I operated on the superior maxillary branch of the nerve, removing all of that portion of the nerve lying in the infra-orbital canal, and at the same time resected more than two inches of the inferior maxillary nerve. Relief from this operation was short, and in November of the same year the patient came to Hope Hospital, where I removed the ganglion. A large opening was made in the skull, the dura was lifted, the superior and inferior maxillary nerves were grasped with forceps, pulled well out of their respective foramina and divided. The ganglion was then split from before backward between the ophthalmic and superior maxillary trunks and removed. The aim was to avoid injury to the ophthalmic division of the nerve. The middle meningeal artery was not injured. The hemorrhage, as is usual, was considerable and principally venous, and was controlled by gauze packing. After the removal of the ganglion, the wound was closed with buried catgut sutures, a few strands of catgut being used as a drain. The eyelids were not sewn together. The wound healed by first intention, recovery was prompt, and the man remains, thirteen months after the operation, free from pain. Sensation in the cornea was not completely destroyed, but was lessened by the operation. On the

day after the operation, a facial paralysis was noticed on the side of the operation. This paralysis proved to be permanent.

Microscopic Examination—The report of the pathologist, Dr B W Rhamy, is as follows "In the section of Gasserian ganglion I find a small amount of leucocytic infiltration, the evidence of a slight chronic inflammation. Also hyperplasia of the interstitial connective tissue, or fibrosis, and some degeneration of ganglion cells, probably from pressure. The condition here is probably the result of chronic hyperemia or inflammation"

Paralysis of the facial nerve, resulting from removal of the ganglion of Gasser, so far as I am aware, has not been reported before. There was no evidence of infection about the wound. There was no traumatism inflicted that could have involved the trunk of the facial, either inside or outside of the cranial cavity, provided it occupied, in this subject, its usual position. But two explanations occur to me, of this unusual sequel, either the paralysis of the facial was a mere coincidence or the course of the nerve was in this subject unusual.

Since this report was written, a third explanation of the cause of the facial paralysis was suggested to me by Mr Harold Mouser, a medical student of mine, and I am inclined to regard it as the most probable one. He suggested that the facial nerve was traumatized by traction of the chorda-tympani.

INFECTION WITH FLY LARVÆ, *ANTHOMYIA CANALICULARIS*

H C BLANKMEYER, M.D.

Bacteriologist, Illinois State Board of Health
SPRINGFIELD, ILL.

An interesting case of infection with this larvæ was brought to my observation in May, 1906, by Dr George E Lyon, Toledo, Ill. With the assistance of Mr N C Gilbert of the University of Wisconsin, a practical zoologist, the identification was made and a search through literature revealed but seventeen cases heretofore reported, as follows: Five in America, five in Germany, and the remainder scattered throughout France, England, Sweden and the Argentine Republic, a rather wide range of territory.

Anthomyia canalicularis is the larva of the very small black house fly so often seen on windows. The flies, which are often found parasitic in man, lay eggs on decaying vegetables, the larvæ varying in size from $\frac{1}{8}$ to $\frac{1}{4}$ inches in length. The body proper is long and narrow, has developed lateral branches or gills, and is divided into segments, ten or fourteen, according to age. They are beset bilaterally with feathered bristles two to each segment. The larvæ are light brown in color and when passed in the stools are more or less active. They invade the intestine and produce alarming symptoms until vomited up or passed with the feces. The life of the larvæ in the human intestine is about two weeks. They are ingested as eggs and hatched out in the small intestine and are highly resistant to all forms of treatment.

Patient—B B, male aged 30 native of Illinois single, weight 145 pounds, height 5 feet 5 inches, occupation rural mail carrier.

Personal History—The patient's habits are good. He drank some beer last summer in hopes of gaining relief. He takes a glass only occasionally now. He lived on farm for twenty years. When six or seven years of age he was troubled with *Ascaris lumbricoides* but vermifuges relieved all symptoms. The patient was a driver in a livery stable until 27 years old since which time he has been a rural mail carrier. He has never been in robust health.

Present Illness—Twelve years ago last June the present illness began. He felt drowsy for a week or two, and the day after a sixteen mile ride on horseback was attacked with severe abdominal pains, which could not be relieved by home remedies. Treatment by a physician (the nature of which the patient does not know), resulted in a bloody diarrhea, followed by constipation. This condition existed for several months, and was followed by very severe pains in the region of the liver. A diagnosis of pleurisy was made at this time, but the pain continued more or less for about six years, during which interval the patient was markedly constipated. The constipation continued but the pain became transferred from the right hypochondrium to the head, where it existed when the patient was seen. During the past six years the patient has consulted many physicians, has been to various mineral springs and to the dispensary of a medical school, has taken great quantities of "patent medicine," all to no purpose.

Examination—Patient's condition in April was as follows: Pulse, soft and full, eyes dull, with pupils constantly contracted, respiration normal, temperature normal, appetite different, bowels sluggish, abdomen tympanitic—full even after catharsis. Urine high colored, with much uric and hippuric acid. Pain, severe, constant headache with pains radiating from lumbar region upward along the spine to base of brain.

Treatment—In April this consisted of Potassium citrate, saw palmetto, liquid couch grass, fluid extract corn silk, sandalwood and compound spirits of ether, capsules containing strychnin, arsenous acid, podophyllum, salol, monobromated camphor and pepsin. This treatment was continued for three weeks and resulted in loss of all pain except frontal headache, but the benefit was only transitory. The patient was then lost.

Drawing of the larva of *Anthomyia canalicularis* (enlarged), (Braun)

sight of until the middle of May. On Saturday, May 19, he began eating raw pumpkin seeds and continued same without food until Tuesday morning, when a saline purge was given. At noon on Tuesday he passed about a quart of fecal matter fairly alive with the larvæ of *Anthomyia*, perhaps 1,000 or 1,500 in all. He was then put on santonin, calomel and male fern, with no further result than to empty the intestinal tract completely. The abdomen decreased five inches in circumference and patient slept during the two following nights better than for months. An examination of the urine at this time showed nothing abnormal except some spermatozoa, few in number. Three days later a few more larvæ were passed, which showed that the whole colony did not come away at once. The patient's condition since June 1, 1906, was about the same. He continued to pass a few larvæ from time to time for several weeks after the first evacuation. He was then treated for a time by one of the foremost medical men in the middle west, until he located at Colorado Springs, from which place he was reported as improving. On January 21, 1907, the patient reported that he was feeling much better and gaining flesh. He had just returned from Colorado and engaged in business. He reported he was free from headache, but not entirely well although no reference was made to the larvæ.

The Evolution of Medical Thought—Medical science is constantly in a process of evolution. The apparent truths of today are the fallacies of tomorrow, and too often the results of the researches of many years are quickly forgotten. —I B Young M.D., in the Bull of Am

AN AMPUTATION RETRACTOR

O O COOPER, M.D.
Chief Surgeon the Hinton Hospital
HINTON, W. VA.

For years in doing amputations I have felt the need of some sort of efficient retractor to take the place of the two-tailed or three-tailed cloth retractor commonly used. The cloth sometimes holds the soft parts away from the saw, but frequently does not, the consequence being that the muscles are shredded or bruised enough to cause sloughing, or, on the other hand, the bone is not sawed off high enough the first time.

No instrument catalogue that I know of shows an amputation retractor of any sort, and the surgeons I

Fig 1—The amputation retractor

meet have not heard of such a device, so, as far as I know, I have the only pair of amputation retractors in existence. At first I used two kidney-shaped pieces of sheet copper cut out by hand. By overlapping these around the bone and bending them a little at the periphery to keep one's fingers away from the saw the success of the idea has been demonstrated in numerous amputations. Recently I asked Max Woche & Son, Cincinnati, to follow up my idea and make me a pair of retractors with convenient handles. The cuts show the result of their efforts with which I am well pleased.

The instruments are used in pairs and each consists of a blade to which a handle is rigidly attached at right angles. The convex edge of the blade is a part of a circle six or seven inches in diameter. The concave edge is part of a circle one and a half inches in diameter, gradually widening. The handles are six and a half inches long and attached to the stump side of the blade so as to leave the saw side of the blade smooth. In use, the blades are applied around the bone opposite each other and then overlapped until they fit the bone snugly, when the desired retraction can be made. They will fit a bone of any size or two bones of different sizes, as in the leg or forearm. By overlapping the blades at various angles the shape of the opening can be modified at will.

Fig 2—The overlapping of blades and the opening left for the bone

are applied around the bone opposite each other and then overlapped until they fit the bone snugly, when the desired retraction can be made. They will fit a bone of any size or two bones of different sizes, as in the leg or forearm. By overlapping the blades at various angles the shape of the opening can be modified at will.

The Safe Kind of Whisky—Dr. Waler, of the Department of Agriculture according to *Harper's Weekly*, says that the safe kind of whisky is that which is bottled, "the records show that whisky left in a bottle has never injured any one seriously."

BITE OF A POISONOUS SPIDER, *LATRODECTUS MACTANS*

ALEXANDER L. HODGDON, M.D.
Formerly Professor of Nervous Diseases and Diseases of the Mind
Maryland Medical College, Baltimore.
PEARSON, MD

The toxic qualities of the spider that is known as *Latrodectus mactans* are not, I believe, generally known. An appropriate name for the spider would be the "T and dot" spider, as the specimen I have seen was coal black with a red T and red dot.

Some weeks ago I was called to see a man who, pulling on his boot, had pressed on one of these spiders with the side of his foot. The spider's bite at the time caused him but little pain or inconvenience. About twenty five minutes after being bitten, however, acute and agonizing pains occurred all over the body, being particularly severe in the region of the chest. Aqua ammoniac was applied locally and also administered, well diluted, internally, and previous to my arrival the patient had taken considerable whisky. Morphine sulphate, strychnine sulphate and nitroglycerin were administered hypodermically, and while the latter two drugs may have helped his condition I believe the morphine was of much greater benefit. For about forty eight hours the symptoms were most severe, the most acute pains lasting for about eight hours, the man did not feel entirely well for about ten days.

It would seem from this case that the *Latrodectus mactans* must secrete a very concentrated poison which acts, when absorbed, as a direct irritant to the sensory nerves. I am interested to know just what the active principles of this poison are.

[COMMENT] The group of animals referred to belongs in the same subkingdom as the insects, from which they differ, however, in important characters. Several species have gained considerable reputation in medicine. Probably the most noted spider in this respect is *Tarantula fasciventris* of Italy, the bite of which was popularly supposed to cause the disease tarantism or tarantula dance. Another noted spider is *Latrodectus malmignatus*, which is reported to have produced such fear in Spain in 1830 and 1833 that farmers hardly dared to leave their houses. An American species, *Phidippus tripunctatus*, is reported as causing, by its bite, a swelling, accompanied by great pain, itching and inflammation, chilliness and fever succeed each other in rapid succession and in children and in weak persons convulsions may result, the pain is said to last several days and to disappear only after free perspiration. The so-called "bird spiders" of the tropics are nocturnal animals feared because of their poisonous bites, which are very painful, but probably not so dangerous as claimed. *Ananias hentzi* is a bird spider or tarantula sometimes found in the eastern states, and *A. rileyi* is a California species with a still less savory reputation. In 1902 Dr. H. W. Crause published in the Transactions of the State Medical Association of Texas accounts of a number of cases of spider bites observed in Texas. *Latrodectus mactans* has been charged with numerous serious bites in this country, and while some cases have been alleged to end fatally, many of the accounts lack sufficient details to justify any valid judgment. Dr. L. O. Howard has shown that at least some of the cases may have been due to bites of the pirate bugs. Some cases of very severe bites due to *L. mactans* seem, however, to be well established. It is particularly on the glans penis that persons are bitten, when in box privies.—Ed.]

FOLDING ESMARCH ANESTHESIA MASK

VICTOR F. MARSHALL, M.D.
APPLETON, WIS.

The accompanying illustrations show a modification I have made of Esmarch's anesthetic mask. The hoop wires are supplied with joints at the ring base, thus allowing the hoops to be folded on each other. This gives

a flat instrument, which lends itself easily to packing into small compass. The modification was worked out owing to the fact that the ordinary surgical and obstetric bags contain too little room. Our modern armamentarium is bulky and economy of space is desirable. The instrument is simple, durable and compact.

A SIMPLE STERILIZER FOR EMERGENCY AND COUNTRY WORK *

EDWARD S. STEVENS, M.D.
LEBANON, OHIO

It is one thing to prepare for operative work with the modern pressure sterilizer and other conveniences of the hospital, it is quite another thing to prepare for the same work in a private home, perhaps on a farm at a distance from the operator's office. The device offered is purposely presented in a crude form to show what may be done under such circumstances when the element of time is important. An instrument maker could give us a more sightly instrument. All that is required is a piece of No. 9 or 10 wire, a sheet of wire netting, four cords for suspension and an equal number of metal hooks. In this case poultry netting was used; the cords were wire picture-cord, and the hooks were ordinary picture hooks. But any strong cord will answer and a hook may be speedily fashioned from sheet tin or iron.

The wire is shaped to fit loosely the inside of the house wash-boiler. The wire netting is bent and fastened over this frame; the cords are attached near the ends of the straight sides and are of such length as to let the apparatus into the boiler to within a few inches of the bottom, the hooks attached to the upper ends of the cords are placed over the upper rim of the boiler. This gives a steam sterilizer with considerable space. Boilers are usually found in one of three sizes—most commonly the No. 8.

In using this simple apparatus a few inches of boiling water are placed in the boiler, the sterilizer is hooked over the rim of the boiler, and dressings, bedding and towels may then be steamed as long as may be desired. To prevent the condensation of the steam in the sterilized articles they may be placed for a few minutes in the oven, when they will be found to be dry enough for use.

I have found this little apparatus a great time-saver.

when called on for work which allowed little time for preparation. It is also a convenient article for the nurse who is sent ahead to prepare for the coming of the surgeon. By folding the cords and hooks over the wire netting it may be packed flat and is easily carried.

AN IMPROVED PETRI DISH HOLDER *

HAROLD O. RUH
Assistant in Pathology, Indiana University
BLOOMINGTON, IND.

Any one who has attempted bacteriologic work involving the use of a large number of Petri dishes, has regretted the lack of a satisfactory Petri dish holder. No holder, satisfactory for the various procedures of sterilization, storage, plating and incubation is on the

market. To supply this defect there has been designed the holder here presented.

The figure is self-explanatory. The instrument is made of heavy tin, galvanized iron or other material that will withstand an ordinary amount of heat and moisture, and is made with pre-curved joints without solder. The apparatus has been found satisfactory so far as tested.

* Presented at the January meeting of the Warren County (Ohio) Medical Society.

* From the Pathological Laboratory of

THE ATLANTIC CITY SESSION

American Medical Association, Fifty-Eighth Annual Session, Atlantic City June 4-7, 1907

OFFICIAL CALL

THE FIFTY EIGHTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, TO BE HELD AT ATLANTIC CITY, N J, JUNE 4, 7, 1907

To the Officers and Members of the Constituent State and Territorial Associations of the American Medical Association

The fifty eighth annual session of the American Medical Association will be held at Atlantic City, N J, on Tuesday, Wednesday, Thursday and Friday, June 4, 5, 6 and 7, 1907

THE HOUSE OF DELEGATES

The House of Delegates of the American Medical Association will convene at Atlantic City, N J, at 10 a m, on Monday, June 3, 1907 The representation in the House of Delegates of the various constituent associations for the years of 1907, 1908 and 1909 will be as follows

Alabama	3	Montana	1
Arizona	1	Nebraska	2
Arkansas	2	New Hampshire	1
California	3	New Jersey	3
Colorado	2	New Mexico	1
Connecticut	2	New York	11
Delaware	1	Nevada	1
Dist. of Columbia	1	North Carolina	3
Florida	1	North Dakota	1
Georgia	2	Oklahoma	2
Hawaii	1	Oregon	1
Idaho	1	Pennsylvania	8
Illinois	7	Rhode Island	1
Indiana	4	South Carolina	2
Iowa	3	South Dakota	1
Kansas	3	Tennessee	2
Kentucky	3	Texas	5
Louisiana	2	Utah	1
Maine	1	Vermont	1
Maryland	2	Virginia	3
Massachusetts	6	Washington	1
Michigan	4	West Virginia	1
Minnesota	2	Wisconsin	3
Mississippi	2	Wyoming	1
Missouri	4	Philippine Islands	1
Ohio	6		

The twelve sections of the American Medical Association the Medical Department of the Army the Medical Corps of the Navy and the Public Health and Marine Hospital Service are entitled to one delegate each

FIRST GENERAL OR OPEN MEETING

The first General Meeting, which constitutes the opening exercises of the scientific functions of the Association, will be held at 10 30 a m, Tuesday, June 4

REGISTRATION DEPARTMENT

The Registration Department will be open from 8 30 a m until 5 p m, on Monday, Tuesday Wednesday and Thursday June 3, 4, 5 and 6 and from 9 to 10 a m on Friday, June 7

WILLIAM J MAYO, President
CLIFFORD H SIMMONS, General Secretary

PRELIMINARY PROGRAMS OF SECTIONS

The Papers to be Read at Atlantic City—Announcement About the Official Program

The following is a partial list of titles of papers to be read before the various sections at Atlantic City Some other papers are also announced to be read, but the titles have not yet been received. The order here is not necessarily the order which will be followed in the Official Program This Official Program will be similar to those issued in previous years and

will contain the final program of each section, with abstracts of the papers, lists of committees, programs of the General Meetings and of the meetings of the House of Delegates, lists of entertainments, map of Atlantic City, etc To prevent misunderstandings and to protect the interests of advertisers, etc, it is here announced that this Official Program will contain no advertisements It is copyrighted by the American Medical Association and will not be distributed before the session A copy will be given to each member on registration

SECTION ON PRACTICE OF MEDICINE

CHAIRMAN, T D COLEMAN, AUGUSTA, GA, SECRETARY, JOSEPH L. MILLER, CHICAGO

The Early and Premonitory Symptoms of Progressive Pernicious Anemia John A Lichty, Pittsburg

Joint Meeting with the Sections on Surgery, Pathology and Physiology

- The Physiology of the Thyroid Gland in Its Relation to Exophthalmic Goiter S P Beebe
- The Pathology of Exophthalmic Goiter W G MacCallum, Baltimore
- The Diagnosis of Exophthalmic Goiter Lewellys F Barker, Baltimore

SCIENTIFIC EXHIBIT

FRANK B WYNN, Indianapolis Director

The Scientific Exhibit consists of two parts

1 Continuous Demonstrations

These are of gross and microscopic specimens, of apparatus models charts photographs, etc, and are conducted by those personally in charge of the respective exhibits The exhibits represent great variety and many are noteworthy in character

2 Amphitheater Demonstrations

These formal demonstrations will occur on Wednesday and Thursday afternoons from 2 o'clock to 5 and will be participated in by W M L Coplin, Charles H Frazier W S Hallsted Ludvig Hektoen F Robert Zeit W G MacCallum M P Ravenel Richard C Cabot Lawrence F Flick, I M McCarthy J F Greive, W S Hall and others

REGISTRATION

Suggestions and Rules for the Guidance of All Who Will Attend the Session

The Registration Department will be on Young's Pier For admission to the different section meetings exhibits and entertainments, it will be necessary for every member of the Association to register his name and those of his guests and to obtain the official badges provided by the Committee of Arrangements No one will be admitted to any meeting or entertainment without a badge

The Registration Department will be open from 8:30 a m to 5 p m on Monday, Tuesday, Wednesday and Thursday June 3 4 5 and 6 and on Friday June 7, from 9 to 10 a m

Members are requested to observe the following directions:

1 Each physician desiring to register will fill out a registration card

2 Each member who has paid his annual dues in full will present his pocket card and this registration card at a window marked "Registration by Receipt"

3 The registration of members who have paid their dues but who have lost their receipts will require a moment or two of extra time, while the records are consulted

4 Members who have not yet paid their dues will present registration card and make payment at a window marked "Cash"

5 Each applicant for membership will present his registration card at a window marked "New Members Make Application Here" with a certificate that he is a member in good standing in his state society (Every such prospective member however will save him self delay and annoyance by sending in his application before the session All such letters should be mailed not later than May 25 to the American Medical Association 103 Dearborn Avenue Chicago as the records have to be packed and shipped to Atlantic City early)

6 Each member on registration will receive a copy of the Official Program as well as a copy of the Official Program as may be necessary

America's Greatest Resort.

ATLANTIC CITY—WHERE THE ASSOCIATION HAS
BEEN WELL ENTERTAINED TWICE

W BLAIR STEWART, A.M., M.D.
ATLANTIC CITY, N. J.

Atlantic City, the playground for the whole world and the greatest seaside health resort, has grown from a few summer cottagers in 1854 to a city of 40,000 permanent citizens. Dr. Jonathan Pitney of Absecon, N. J., a member of our own profession, recognized in the large island of sand five and one half miles to the southeast of the New Jersey coast the unprecedented advantages for giving his patients the open air treatment for disease. While not the first to visit Absecon Island, for that is the name of the island on which Atlantic City is located, he was practically the real promoter of the present magnificent city.

The first railroad to Atlantic City was built in 1850 and with it gradually came the summer cottager and permanent resident. It was only the matter of a few years before the beneficial qualities of the air and the peculiar geographic location of the island five and one half miles at sea and facing the south dawned on the physicians of Philadelphia and other nearby eastern cities. The phenomenal growth of the city and the gradual recognition of its merits are now the matters of history.

With a permanent population of 40,000 we increase to 300,000 by the height of the season in August, and, what is more gratifying, this large army is properly housed, dined and entertained. The capacity of the hotels without crowding ranges from 1,100 down to the small boarding house and cottage. With 100 large hotels, over 800 smaller hotels and boarding houses, and about 8,000 cottages and other buildings, one can readily realize the ease with which one's comforts can be met. Atlantic City's one aim is the entertainment and comfort of her guests, she can not be classed as a manufacturing or commercial center. Our terminus is in the ocean and our only commodities in trade are fresh air, sunshine, good accommodations, wholesome food, pure water and the pleasure and health of our guests.

The ocean and beach front with its six miles of Boardwalk are the leading attractions. What more can one wish? The continuous ebbing and flowing of the tides, the never ceasing rolling and breaking of the waves, the ever present line of whitecapped billows, the gentle song of the sea, sometimes fine and mild and at other times rough and boisterous, all tend to make the initial visit of the stranger one grand dream. Lost to the world, lost to self, all care and trouble forgotten, silent sentimentalisms pleasurable emotions, poetic thoughts, hours of admiration—the typical reveries of the tenderfoot's first view of the ocean. Is it any wonder that trouble is forgotten, health benefited and cares neglected?

THE BOARDWALK

Atlantic City's Boardwalk is unique, and nowhere in the world can you find its duplication. A steel structure with a Georgia pine deck, elevated from five to fifteen feet above the beach, six miles long and twenty to sixty feet in width. On one side is an unobstructed view of the ocean and beach while the other is lined by hotels, places of amusement and bazaars. It is on this structure that you will find a regular kaleidoscopic moving mass of humanity representing every state in the Union and every civilized nation of the earth. "Babel let loose," as one expressed it. In fact "Meet me on the Boardwalk at Atlantic City" has become one of the world's words.

Five piers, each over 1,000 feet in length extend from the Boardwalk into the sea and on them one can find amusement, recreation, fishing or a peaceful rest at all times of the year. Open in summer and heated in winter the music halls provide the very best high class music. Sitting on the extreme end of the piers in an easy chair watching the rolling waves, is the full equivalent of a real sea voyage but lacking the roll and toss of the vessel and the too oft experienced seasickness.

At night one can imagine himself in fairyland under the myriad thousands of small electric lights overhead and all around, for the Boardwalk and many buildings are one blaze of light. This illumination alone more than repays one for the trip to this city.

RECREATION

Yachting and fishing are two forms of entertainment and recreation always available. Here one can have a sail on the bays and thoroughfares on smooth water or directly on the ocean, where the roll and toss of the waves are fully experienced. Atlantic City is not a port of entry and does not afford the presence of an idle, undesirable, illiterate class of rough seafaring men. The whole city and Boardwalk are so carefully policed at all times of the day and night that ladies can come and go without escort or fear of molestation.

The Country Club, located at Northfield, seven miles away, affords every opportunity for golf and other outdoor sports at all seasons and can be reached by trolley at any hour. So varied are the many sources of amusement, exercise and recreation that "dull care" never finds opportunity. Stormy and rainy days? Yes, we have a few, but a trip to Atlantic City is not complete without an opportunity to see the "demons of the deep" toss the spray and waves into a fury not soon to be forgotten. Not dangerous when viewed from a hotel window or the Boardwalk, but often disastrous to the poor mariner at sea in a frail craft.

The sewage plant of Atlantic City works on the gravity system. The sixty miles of sewer pipes flow into a common station, whence the sewage is pumped through large pipes into Beach Thoroughfare, several miles back of the city, where billions of gallons of sea water ebb and flow twice daily. So complete is the dilution of the sewage by the time it reaches the ocean in front of the city that it can not be detected by the most delicate tests. Atlantic City is the only seashore resort on the Atlantic Coast that does not discharge its sewage into the ocean directly in front of the city. The plant's average pumping capacity for 1906 exceeded 8,000,000 gallons daily.

WATER SUPPLY

No purer water supply is given to any city than the mixed artesian and cedar water of Atlantic City. There are fifteen active artesian wells that supply 4,000,000 gallons of the purest, clear, sparkling water obtainable at any place. With new appliances being installed, it will be possible to increase the output of these wells sufficiently to supply the entire demand of Atlantic City for water from October to June. The present daily consumption during the months of October to June is 6,500,000 gallons. In August, 1906, it required 10,200,000 gallons daily to supply the city. The additional water comes from a protected cedar grown watershed entirely free from possible contamination. The last monthly examination of the water supply made by Dr. Henry Leffman and Dr. David H. Bergey of Philadelphia showed a strictly safe and potable water, nearly chemically pure, with no suspicious bacteria of any kind. Many of the largest hotels supply their own water of purest quality from artesian wells driven to a stratum 800 to 900 feet deep. There are no fresh water streams or ponds within six miles of Atlantic City, hence a scarcity of mosquitoes and a positive absence of malarial influences.

CLIMATE

The climate of Atlantic City is so pleasant, balmy and sunny on the average that thousands no longer seek health in the South, but spend their time here. This is more and more recognized each year by physicians, who send their convalescents by the thousands at all times of year. The Weather Bureau of the United States Department of Agriculture, located in Atlantic City, reports, during thirty-three years, an average of 61 per cent of sunshine, 123 clear days, 137 partly cloudy days, and 105 cloudy days. The normal temperature in January is 32, February, 33, March, 30, April, 48, May, 58, June, 67, July, 72, August, 73, September, 68, October, 57, November, 46, December, 36, annual average, 52. These temperature ranges apply to the weather bureau station but not to the Boardwalk. Here the average winter

temperature is from two to ten degrees higher, while the summer temperature is two to ten degrees cooler. This is due to the protected southerly exposure, the warmer water radiations in winter and the cooler in summer. Invalids take advantage of these facts and are able to spend at least 65 to 70 per cent of their time on the Boardwalk. From October to March the prevailing wind is northwest, from April to September it is southwest.

The rolling chair habit has grown to such phenomenal proportions that not only do invalids use these easy vehicles, but the average visitor can make use of them as he would of the busses and carriages. This affords every opportunity to enjoy the climatic influences and the beauties of the sea. The classes of invalids most benefited are convalescents, anemics, patients who have been operated on, neurasthenics, debilitated and diseased children, overfatigued business men and women, those with incipient tuberculosis, malaria, heart affections and catarrhal conditions (for a limited time), about 50 per cent of rheumatic and asthmatic patients, and all who need fresh air, sunshine, exercise, relaxation and rest. Every facility is offered by the City Hospital, sanatoria and private cottages for any form of treatment within the range of modern medicine and surgery. Surf bathing, hot and cold sea water bathing and treatments are available. It is unnecessary to advise the profession at large of the merits and demerits of climatic influences, but it is well to caution against hoping for things impossible by sending patients in the last stages of disease away from comfortable homes to die in a hotel or a boarding house at this or any other resort.

The general health of Atlantic City's population is remarkably good, largely on account of climate, the wholesome food and water supply and an efficient health law that is strictly enforced. Typhoid fever is practically unknown except for a few cases that are imported each year. The public schools have a system of medical inspection conducted by eleven regular physicians. By this means and by the action of the board of health contagious diseases are limited to a very few cases.

THE CITY ITSELF

Just a word or two about the city in general. There are ten school buildings graded to the highest standard, preparing scholars for any college, thirty churches representing all denominations, a most efficient paid fire department of four teen separate companies, an efficient corps of municipal life guards and medical men on the beach during surf bathing seasons, eight banking institutions and trust companies of the highest rank—in fact, everything that goes to make an up to date city. There is no city in the world better able to care for conventions of all sizes and to give almost unlimited accommodation of the very best kind without crowding and overcharging. An influx of 10,000 to 20,000 people is no longer a novelty, and they are so well cared for and with such little effort that their presence is scarcely noticed except on the Boardwalk.

Our hotels range from the palatial beach front structures of steel and concrete to the more unobtrusive little boarding houses on the side streets. Money has not been spared in providing for the comforts of their guests. One can find every home comfort at command winter and summer. The rates charged by these hotels are within the reach of all and are proportionately low when compared with other cities. Many of them supply hot and cold fresh and sea water baths with each suite of rooms. Special diet kitchens for the preparation of food for invalids and the sick are noticeable features of the best hotels. For the benefit of those who expect to attend the coming convention of the American Medical Association in Atlantic City a list of approved hotels is appended. In engaging rooms it is best to communicate directly with the hotel desired for reservations. There will be no crowding of guests because of lack of room, as ample provision has been made for every one who comes. Below is given a list of the leading Atlantic City hotels with the location, capacity and rates, a list of headquarters and a list of section meeting places.

The general headquarters for registration, information and exhibits will be located on Young's Pier Tennessee Avenue and the Boardwalk, where every one is requested to register immediately on arrival in Atlantic City. The Bureau of Information on this pier will give all data respecting hotels, meeting places and other points desired.

EXCELLENT RAILROAD SERVICE.

Probably no other city of its size has a better railroad service than Atlantic City. The Pennsylvania, the Reading, the Jersey Central and the electric lines all maintain the finest equipment of their systems on their Atlantic City branches. The tracks are all stone ballasted and protected by the automatic signal system. The fastest express trains run at very frequent intervals. It is a noticeable fact that out of the thirteen fastest trains maintained in the world nine are scheduled on the Atlantic City systems. Speed, safety, comfort and luxury are the watchwords of the railroads. Special cars and trains will be made up and run through to Atlantic City without change for the coming session in June. The passenger associations have granted an excursion rate of one first-class fare plus \$1. The present return limit is June 10. The Transportation Committee is endeavoring to have a further extension and if it is obtained due notice will be given in *THE JOURNAL*. Special attention is also called to the Souvenir Booklet to be mailed by the regular medical profession of Atlantic City about May 1, to every member of the American Medical Association. This with the circular from the local Committee of Arrangements will supply additional data and take the place of the usual Souvenir Booklet given out at the time of the session.

The local Committee of Arrangements has made every preparation for an exceptionally large meeting and extends a hearty welcome to every member of the American Medical Association who can possibly attend the Atlantic City session. Entertainment has been provided for the visiting ladies and guests and members of the Association. These functions will be announced at the time of registration. Additional information will be gladly given by the members of the local committee the personnel of which follows:

COMMITTEE ON ARRANGEMENTS

W. Blair Stewart, Chairman, North Carolina and Pacific
Avenues
Edward C. Union, Secretary J. Addison Joy, Treasurer

MEETING PLACES

Convenient and Commodious Places for the Various Sections and General Meeting

The following is a list of the various meeting places arranged by the Atlantic City Committee for the various General Meetings and for the several sections

OPENING SESSION (Tuesday at 10 30 a m)
Auditorium Youngs New Pier
EVENING SESSIONS (Orations) Casino Hall Steel Pier
HOUSE OF DILL GATES Tower Observation Hall Hotel Traymore
TRUSTEES ROOM Marlborough House
PRACTICE OF MEDICINE Casino Hall Steel Pier
SURGERY AND ANATOMY Music Hall Steel Pier
OBSTETRICS AND DISEASES OF WOMEN Dance Hall Steel Pier
DISEASES OF CHILDREN Ocean Parlor Hotel Traymore
LARYNGOLOGY AND OTOTOLOGY Baptist Church Pacific and Pennsylvania Aves
OPHTHALMOLOGY First Presbyterian Church Pacific and Pennsylvania Aves
NERVOUS AND MENTAL DISEASES Brighton Casino
HYGIENE AND SANITARY SCIENCE Sun Parlor Steel Pier
CUTANEOUS MEDICINE AND SURGERY Park Avenue Hall Hotel Marlborough

PATHOLOGY AND PHYSIOLOGY Dennis Sun Parlor, Dennis Hotel and Scientific Exhibit Hall for special meetings on Youngs Pier
PHARMACOLOGY AND THERAPEUTICS Ocean Hall, Marlborough
STOMATOLOGY Casino Hall, Committee Room No 1 Steel Pier
REGISTRATION AND BRANCHES BUREAU OF INFORMATION Main Entrance Youngs Old Pier
POSTOFFICE TELEGRAPH TELEPHONE AND BUREAU OF INFORMATION Marine Hall, Youngs Old Pier
COMMERCIAL AND SCIENTIFIC EXHIBITS Marine Hall Youngs Old Pier
PRESIDENT'S RECEPTION Music Hall Steel Pier
LADIES' AFTERNOON TEA Hotel Marlborough Blenheim

ATLANTIC CITY HOTELS

Ample Accommodations for All will be Found Easily in This City of Hotels

HEADQUARTERS

OFFICERS AND GENERAL HEADQUARTERS	Marlborough Blenheim
PRACTICE OF MEDICINE	Hotel Dennis
SURGERY AND ANATOMY	Hotel Chalfonte
OBSTETRICS AND DISEASES OF WOMEN	Haddon Hall
DISEASES OF CHILDREN	Hotel Traymore
OPHTHALMOLOGY	Hotel Seaside
LARYNGOLOGY AND OTOTOLOGY	Hotel Strand
NERVOUS AND MENTAL DISEASES	Hotel Brighton
HYGIENE AND SANITARY SCIENCE	Hotel St. Charles
CUTANEOUS MEDICINE AND SURGERY	Marlborough Blenheim
PATHOLOGY AND PHYSIOLOGY	Hotel Shellburne
PHARMACOLOGY AND THERAPEUTICS	Marlborough Blenheim
STOMATOLOGY	Hotel Traymore

The following alphabetical list of the leading hotels of Atlantic City gives the address of each, the capacity, the plan whether European, American or both—and the rates per day for one person. The numbers in parentheses following the names refer to the location on the map. The hotels given in capital letters are those which have been selected as headquarters for the various sections, etc.

ABBEY (11) Pacific and Mt. Vernon Aves., 350 American and European \$1.50 to \$2.50
ACME (13) 123 So. Kentucky Ave., 40 American \$1.50 to \$2.50
ALBEMARLE (32) Virginia Ave., near Beach 350 American, \$2 to \$5
ALBION Atlantic and Massachusetts Aves 150 European \$1 to \$2
ALGONQUIN South Carolina Ave near Beach 100 American \$1.50 to \$3
ARCHDALE St. James Place near Beach 150 American \$2 to \$2.50
ARDMORE (37) Virginia Ave near Beach 125 American \$2 up
ATLERY 20 So. Michigan Ave 150 American \$1.50 to \$2
BATES' INLET HOTEL Inlet and Boardwalk 35 European \$1 to \$1.50
BEAUMONT (18) 130 So. Tennessee Ave 200, American \$1.50 to \$2.50
BERKSHIRE INY (43) Virginia Ave., near Beach, 300 American \$2 to \$5
BERRY'S Maryland and Arctic Aves. 20 American and European Amer \$1.50 to \$2
BINGHAM (15) Pacific and New York Aves 100 American and European \$1.50 to \$2.50
BOTHWELL (30) Virginia Ave near Beach 250 American \$2.50 to \$5
BRIGHTON (8) headquarters Nervous and Mental Diseases In diapa Ave and Boardwalk 300 American rates on application
CEDARHURST (22) South Carolina Ave near Beach 250 Amerl can \$2 up
CHAIFONTE (24) headquarters Surgery and Anatomy North Carolina Ave and Boardwalk 600 American \$4 up
CHELSEA Morris and Brighton Aves and Boardwalk 500 Amerl can \$4 to \$10
CHELSEHAM Virginia Ave rates on application
CLABBY Tennessee and Atlantic Aves 50 men only \$1 to \$3
CLARENDON (33) Virginia Ave near Beach 300 American \$2 \$2.50 and \$3
COLWYN 21 So. Michigan Ave 150 American \$1.50 up
CONTINENTAL Tennessee Ave between Atlantic and Pacific Aves 600 American and European \$1.50 to \$2.50
DAVENPORT, South Carolina Ave., near Beach 200 American \$1.50 to \$2.50
DENNIS (4) headquarters Practice of Medicine Michigan Ave and Boardwalk 600 American \$3.50 to \$6
EARL-MAR HALL Vermont Ave. and Beach 300 American \$2 to \$5
EASTBOURNE (7) Pacific Ave., opposite Park Place 50 American \$2.50 to \$4
EDMIST HOUSE 127 St. James Place 100 American \$2 to \$2.50
EDISON (2) Michigan and Pacific Aves 250 American and Euro pean Amer \$1.50 up Europ \$1 up
ELBERON Pacific and Tennessee Aves 300 American \$1.50 to \$2.50
ELWOOD St. James Place near Beach 150 American \$1.50 to \$3.50
FREDONIA (19) Tennessee Ave near Beach 250 American and European Amer \$2 to \$2.50 Europ \$1 to \$2
GALLEN HALL (48) Connecticut and Pacific Aves 350 American rates on application

GARDEN (9) Illinois and Pacific Aves 300 American and European Amer \$3 to \$6 Europ \$2 up
GARDNER Atlantic and New Jersey Aves 50 American \$2
GLADSTONE Brighton Ave and Beach 150 American \$3 to \$6
GRAND ATLANTIC (41) Virginia Ave near Beach 300 American \$2.50
GREATER PITTSBURGH 142 So Tennessee Ave 100 American \$1.50 up

GENERAL MEETINGS

The Formal Opening Tuesday Morning—The Orations at the Evening Meeting

The opening of the fifty eighth annual session of the General Meeting held Tuesday morning at 10 o'clock in the Auditorium on Young's New Pier. A series of addresses will be made by Dr. Alexander Murray, president.

sey State Medical Society, Hon Edward C Stokes, governor of New Jersey, and Hon F P Stoeck, mayor of Atlantic City. The President elect, Dr Joseph D Bryant, New York City, will be installed and will make an address.

The evening General Meetings will be held at 7 30 p m in the Casino Hall on the Steel Pier.

On Tuesday evening the Oration on Medicine will be delivered by Dr James B Herrick, Chicago, and the Oration on Surgery by Dr William H Wathen, Louisville, Ky.

On Wednesday evening Dr Samuel G Dixon, Philadelphia, will deliver the Oration on State Medicine.

HOUSE OF DELEGATES

Membership of the Legislative Body of the American Medical Association, 1907

As a number of the state associations have not yet held their meetings for 1907, it is impossible to give, at this time, a complete list of the members of the House of Delegates for the Atlantic City session. The following is a list of the hold over delegates and of the newly elected members who have been reported up to the time of going to press.

TRANSPORTATION

One Fare for the Round Trip—Special Trains and Special Parties

The New England Passenger Association, the Trunk Line Association and the Central Passenger Association have granted a rate for the round trip of one first class limited fare plus \$1. Tickets will be sold and good going May 31 to June 4, inclusive, returning, leaving Atlantic City June 4 to 10, inclusive. By deposit of the ticket by the original purchaser, in person, with the special agent at Atlantic City not later than June 10, and payment of fee of \$1 at time of deposit, an extension of the return limit may be obtained to leave Atlantic City not later than June 18.

The Transcontinental Passenger Association granted a one first class 30 day fare for the round trip, tickets to be on sale May 20 and 21. Final arrangements of this association with the eastern passenger associations have not yet been announced, but tickets from the Pacific Coast and Mexico will be good returning within 90 days from date of sale. The Transcontinental Passenger Association covers the western part of the United States, including all of the Pacific Coast.

An attempt was made to extend the time of return which is effective on tickets from points east of the Pacific Coast and Mexico, but the several lines wished to keep the limit at June 18.

Rates to the Jamestown Exposition are mentioned below.

American Medical Special

The Committee on Transportation of the Chicago Medical Society is perfecting arrangements for a special train from Chicago to Atlantic City. This train will be known as the American Medical Special, and will run over the Pennsylvania System leaving Chicago on Sunday, June 2, at 3 p m, and reaching Atlantic City early on Monday morning. The train will be a special electric lighted, solid vestibule train, consisting of two diners, a Pullman observation car, composite smoking car, baggage car and a sufficient number of Pullman sleepers to accommodate all who desire berths. The train will be run from Chicago to Atlantic City without change. The fare will be \$21.50 for the round trip. Sleeping car berth will be \$5. Rules concerning tickets will be as above stated. Stopover privileges in Philadelphia and Washington may be had within the limits of the ticket. Those desiring to return via Washington must secure tickets reading that way. All reservations for accommodations on this train will be made in Chicago at the office of the city ticket agent of the Pennsylvania System, No 248 Clark Street. Berths may be reserved by letter or telegraph. It is anticipated that a large number of physicians from Chicago and points West will engage passage on this train.

An Ohio Special

The physicians of Akron Ohio, have issued an invitation, through the Summit County Medical Society to all members of the profession of the Sixth Councilor District to attend the Atlantic City Session in a body. Special Pullmans will start from Akron and Canton on Monday evening, June 3, and will be transferred at North Philadelphia directly to the Atlantic City train. Hotel headquarters have been selected in Atlantic City and special features are being arranged for the comfort of members of the party. A circular giving the details of the trip has been sent to all members of the profession in the district.

Baltimore and Ohio Route

The Baltimore & Ohio Railroad has made a special rate of \$21.25 round trip from Chicago to Atlantic City, with stopover privileges at Washington, Baltimore and Philadelphia. The fare for a side trip from Philadelphia to New York and return is \$4. The fare from Baltimore or Washington to Norfolk, Va., and return is \$3 on the day boat and \$5 on the night boat. Tickets are good as outlined above. Sleeping car accommodations as well as any further information can be obtained from W. W. Pickering, District Passenger Agent, Baltimore & Ohio Railroad, 244 Clark Street, Chicago.

Missouri Valley Special.

Arrangements are being made for a special train from St. Louis to Atlantic City, to be known as the Missouri Valley Special. This train will be composed of Pullman sleepers, diners and observation cars, and will leave St. Louis on Saturday, June 1, at noon, running over the Big Four and Chesapeake & Ohio Railways, via Indianapolis, Cincinnati and the picturesque resort region of the Virginias. The train will stop over Sunday at Hot Springs, Va. It will arrive at Atlantic City on Monday morning. The return trip will be via New York City, Jamestown Exposition, Richmond and White Sulphur Springs. A cordial invitation is extended to all physicians of the territory covered by this route to join this party with their families and friends, whether members of the organization or not. Secretaries of district and county societies in the west and northwest are invited to make up parties. Special cars will leave Omaha (via Wabash Railroad), Kansas City and St. Joe (via Missouri Pacific Railroad) on the evening of Friday, May 31, arriving in St. Louis early in the morning of June 1, and allowing four hours in that city before the leaving time of the special. All requests for further information or for hotel and sleeping car reservations should be addressed to Dr. Charles Wood Fassett, St. Joseph, Mo.

Special from Detroit.

A special train will leave Detroit over the Michigan Central on Monday evening, June 3, provided one hundred reservations are made, otherwise special Pullmans will be attached to the regular afternoon train. Further announcements regarding arrangements for Michigan physicians will be announced later.

STOPOVERS AND SIDE TRIPS**Clinics in Philadelphia—The Jamestown Exposition**

Railroad tickets which read via Philadelphia, Washington or Baltimore, allow stopover at these places provided the ticket is deposited with the ticket agent at such place immediately on arrival. The ticket must be called for and the journey taken up again before date of expiration.

The Jamestown Exposition

Many will take advantage of the above privilege to make a side trip to the Jamestown Exposition. This exposition will, in a way, be unique in the history of such celebrations. It will have as a part of its attractions the most remarkable marine review ever seen in American waters. In keeping with the event which it commemorates there will be shown side by side the arts and industries as practiced in 1607 and 1907.

It is to be remembered that favorable railroad rates are in effect this summer direct to the exposition. Some may prefer to buy their tickets to Jamestown with stopover at Washington, Baltimore or Philadelphia and make a side trip to Atlantic City at the time of the session.

The New Jefferson Medical College Hospital

In connection with the meeting of the American Medical Association in Atlantic City, June 4 to 7, 1907, the medical profession in Philadelphia purposes providing a number of entertainments for the members of the Association who will necessarily have to pass through that city on their way to the seashore. Among these entertainments will be those connected with the opening of the new Jefferson Medical College Hospital which has just been completed at a cost of \$1,500,000. (See illustration on page 1516.)

On Saturday, June 1, the alumni dinner of the Jefferson College will be held, and to this all Jefferson graduates are

cordially invited. On Monday, June 3, the commencement exercises of the Jefferson College will take place at the American Academy of Music, and in addition to the degrees conferred on members of the graduating class, a number of honorary degrees will be conferred on distinguished physicians. To these exercises which are held at noon, all members of the American Medical Association are also cordially invited.

On Friday, June 7, at 3 o'clock, the exercises in connection with the opening of the new hospital will take place, this date being chosen in order that members of the Association may have an opportunity on their way back from Atlantic City to inspect the new building. At these exercises addresses will be delivered by the Honorable William Potter, ex minister to Italy representing the board of trustees, by Dr. William H. Welch, of Johns Hopkins University, Baltimore, representing the science of medicine, and by Dr. J. Chalmers Da Costa, representing the faculty and the alumni. After the addresses the building will be thrown open for inspection and a collation will be served. Members of the Association are cordially invited to attend all of these functions and a formal invitation will be sent them if the chairman of the committee of arrangements, Dr. H. A. Hare, 1801 Spruce Street, is notified.

The new hospital is equipped not only with all the modern appliances for taking care of the sick in every department of medicine and surgery, but has also been constructed with the dominant idea that it is a teaching hospital, and every facility is, therefore, provided for the adequate instruction of students.

University of Pennsylvania Clinics

The University of Pennsylvania will give clinics for visiting physicians who happen to be in Philadelphia on their way to and from the session. The schedule is as follows:

MONDAY JUNE 3

Some Principles of Dietetics by David L. Fildall at 9 a. m. in the University Hospital.
Exhibition of Gynecologic specimens by Dr. C. Norris from 10 to 12 in the Gynecologic Laboratories.
The Diagnosis and Treatment of Arteriosclerosis by Dr. Alfred Stengel 12 m. in the University Hospital.
An Obstetric Clinic by Dr. B. C. Hirst from 12 to 3 in the University Hospital.
Surgery of Trifacial Neuralgia by Dr. Charles H. Imler at 2 p. m. in the University Hospital.
Demonstrations of the Workings of the Department of Physical Education by Dr. R. Tait McKenzie from 2 to 5 p. m. in the Gymnasium.
Gynecologic Clinic by Dr. John C. Clark from 3 to 5 p. m. in the University Hospital.
Practical Demonstrations in Blood Examinations by Dr. William Pepper from 3 to 5 p. m. in the Medical Laboratories.
Demonstrations of the Treatment of Disease by Bacterial Vaccines (Wright's Opsonic Theory) by Dr. N. Childersleeve from 4 to 5 p. m. in the Laboratory of Hygiene.
Operative Treatment of Suppurating Ears by Dr. B. Alexanderson Randall at 5 p. m. in the University Hospital.

FRIDAY AFTERNOON JUNE 7

Surgical Clinic on Renal and Vesical Cases by Dr. Edward Martin at 2 p. m. in the University Hospital.
Correction of Deviations of the Nasal Septum and Paraffin Injection of Deformities of the External Nose by Dr. Charles I. Cravens at 2 p. m. in the University Hospital.
Principles of Modern Arterial Suture (Arterial Anastomosis and Direct Transfusion) by Dr. J. Edwin Sweet from 2 to 5 p. m. in the Medical Laboratories.
Clinical Lecture on Neurology by Dr. Wm. C. Spiller at 3 p. m. in the University Hospital.
Clinic with Special Reference to Eye Injuries and the Prevention of Infections by Dr. C. F. de Schweinitz at 3 p. m. in the University Hospital.
Surgical Phases of Splanchnostosis by Dr. John C. Clark from 3 to 5 p. m. in the University Hospital.
Intermittent Claudication and Endarteritic Gangrene by Dr. David Fleissner at 5 p. m. in the University Hospital.

SATURDAY JUNE 8

Medical Clinic by Dr. James Tyson at 9 a. m. in the University Hospital.
Demonstrations of Skiagraphy and Skiagraphy by Dr. Howard Langbein from 10 a. m. to 12 m. in the X-ray Laboratory of the University Hospital.
Diagnosis and Treatment of Arteriosclerosis by Dr. Alfred Stengel at 12 m. in the University Hospital.
Mechanism and Significance of the Infant Chills by Dr. Allen T. Smith at 1 p. m. in the University Hospital.
Surgical Clinic on Intracranial Lesions by Dr. Charles H. Imler at 2 p. m. in the University Hospital.
Medical Clinic on Gastrointestinal and Hepatic Diseases by Dr. John H. Meyer at 3 p. m. in the University Hospital.
Adaptation of Subcuticular Sutures to the Operative Field by Dr. B. M. Ansperh from 3 to 5 p. m. in the University Hospital.
Aphasia and Cerebral Centers of Speech by Dr. Charles I. Cravens at 4 p. m. in the University Hospital.
Demonstrations in Ophthalmology by Dr. C. F. de Schweinitz at 5 p. m. in the Medical Laboratory.

Polyerthemia by Dr Joseph Saller at 5 p m in the University Hospital

A bureau of information will be located in the University Hospital, and a buffet luncheon will be served in the same building between 1 and 2 p m

Wills Hospital Eye Clinics

The staff of the Wills Eye Hospital, Eighteenth and Race Streets, Philadelphia, will hold a special clinic for the benefit of delegates and visitors to the American Medical Association on Monday, June 3, at 2 o'clock

Alumni Night and Section Smokers and Banquets

The local Committee of Arrangements desires to announce to the members of the American Medical Association that Tuesday evening, June 4, the first evening of the coming session, has been set apart as Alumni Night as well as for section smokers and banquets. Several college alumni have already arranged for reunions of the graduates who will attend the coming meeting to renew old acquaintanceships and to recall the events of college days. Dr James W Snowball, 1519 Pacific Avenue, Atlantic City chairman of the Committee on Section and Alumni Entertainments, will give all information desired. Section officers who desire special banquets or smokers for Tuesday evening are requested to notify Dr Snowball early so that proper arrangements may be made.

Temperance Lunch.

For nearly twenty years the Temperance League has had a temperance breakfast at the annual meeting of the British Medical Association. Many eminent physicians of Great Britain have joined on these occasions and expressed themselves freely concerning the alcohol problem. At the Toronto meeting last year over 600 were present.

The Society for the Study of Alcohol and Inebriety proposes a similar movement at the coming session. A number of leading physicians, including nearly all the ex-presidents of the American Medical Association, have promised to speak. A warm invitation is given to all medical men and their wives to join on this occasion, and as the lunch and speeches will be limited to an hour or more in the middle of the day, it will in no way interfere with the regular work of the Association. The secretary, Dr T D Crothers, of Hartford, Conn., will be pleased to give any further information.

American Medical Association Outing Club

This club is planning a nine days' trip through the resorts of New Jersey after the session. All members of the Association and their friends are invited to join the party. For further particulars address Dr Edward R Campbell, Bellows Falls, Vt enclosing stamp for reply.

THE COMMERCIAL EXHIBIT

The Exposition of Instruments, Apparatus, Remedial Agents, Literature and Physicians' Supplies at Atlantic City

The most agreeable thing about any successful medical meeting is the solid satisfaction resulting from the interchange of ideas and the personal contact with men having the same aims and ideals. Probably the next most pleasing feature about such a meeting is the pleasure got by examining those various appliances, whether mechanical, chemical or pharmaceutical, which go to make up the physician's armamentarium. Then, too, there is no small amount of gratification to be had by looking over the choice specimens of the bookmaker's art that are to be found at these gatherings. The visiting physician will without doubt derive a keen pleasure from the Commercial Exhibit to be given at the Atlantic City session. This will be enhanced by the absence of some of the few objectionable features that have crept into previous displays. It has been the desire of the officers of the Association having supervision of the exhibit to have it excel in quality rather than in size. How well they have succeeded will be evident to those visiting it. The exposition will be held in the Marine Hall on Youngs Pier. This pier extends from the well known "Boardwalk" for over a quarter of a mile into the ocean. The Marine Hall is the third building from the pier entrance and its position frees it from the objection of too great publicity for a scientific display. It is a large rectangular building nearly 150 feet long by 100 feet wide. Its interior arrangement

is that of an arena with low broad steps extending around its sides. This will permit of an artistic arrangement of the exhibits that could not be obtained on a dead level floor. At the farther end of the hall and within it will be the post office, general office, information bureau and office of the chairman. Just beyond the commercial exhibit and contiguous to it will be the pathologic exhibit. The Association members will have a special entrance to the pier, near which will be situated the registration department. All physicians are earnestly requested to visit the exhibit hall.

We mention below most of the firms that will be represented at this exhibit.

Albosal Light Company, Philadelphia—Space 22

This firm will exhibit and demonstrate its neutral diagnostic light, albosal, which, it is claimed, projects an intense light of about one hundred and fifty candle power. The light is said to give colors their true value and it can be projected into any cavity of the body, where it shows plainly the various membranes in their true form and color. The apparatus for generating this light fits into a leather pocket case and weighs complete only seven and one half ounces.

Entrance to Pathologic Exhibit

W D Allison Company, Indianapolis, Ind.—Spaces 11 and 12

Several styles of operating and examining tables, covering a wide range of usefulness for the gynecologist and genito-urinary specialist, will be shown by this firm. It will exhibit a complete line of instruments, medicine and combination cabinets and also a specialists' chair designed especially for eye, ear, nose and throat work. Experts trained in the handling of these appliances will be in charge of the exhibit, and will demonstrate the efficiency of these pieces of apparatus.

Anatomik Footwear Company, New York City—Space 42

The shoes designed by Dr Harlan P Cole to take the place of braces in the treatment of deformities of the lower limbs will be displayed by this firm. Pictures will be exhibited of patients so treated and of the braces for formerly worn. There will also be shown rational shoes for children and adults which this firm claims perfectly distribute the bodyweight. Such shoes, they say, prevent and relieve flatfoot and all strains, and obviate the use of supports of any kind.

D Appleton & Company, New York City—Spaces 47 and 48

This company numbers among its publications books by such authors as Osler, Holt, Bryant, Babcock, Kelly, Williams, Keyes, Tuttle and Porchheimer, men whose names are known not only to physicians, but to the world at large for their contributions to science and literature. The publications of this firm are mostly of the one volume monographs for the use of the general practitioner.

Armour & Company, Chicago—Space 37

Special attention will be directed by this firm to the suprarenal preparations, desiccated thyroids (U S P) and to the extract of red bone marrow. The definite and uniform strength claimed for these suprarenal preparations should insure uniformity as to dosage and results in their use. The use of desiccated thyroids has never been as extensive as it now is in the treatment of myxedema, cretinism, etc. This company's extract of red bone marrow is said to contain in a physiologically active form, the elements which increase formation of red blood corpuscles.

B & B Apparatus Company, Salem, Mass—Space 14.

Portable high frequency, x ray and electro therapeutic apparatus and appliances will be exhibited by this firm. The exhibit will also include portable high frequency coils of recent design adapted for work by either direct or alternating current. Collapsible fluoroscopes, tube stands, etc. intended for use in connection with a portable equipment, will be part of the display, as will also a coil operated static head breeze and other interesting devices and appliances.

James Barker, Philadelphia—Space 53

The makers of the Barker vibrators will have a competent representative in charge to demonstrate to visitors the unique features of these machines. The field of mechanical vibration is rapidly broadening and this firm claims the credit of having first brought before the medical profession for study and use the finest apparatus for the purpose that a large and thoroughly equipped plant can produce. A visit to its booth will doubtless be worth while, as the exhibit promises to be an interesting one.

Baker Electric Company, New York City—Spaces 31 and 32

This company will have on exhibition its various types of static machine. The revolving plates of these machines are made of a patent fibrous material, while the stationary plates are of glass. The manufacturers claim for these fibrous plates the property of high insulation and guarantee them not to warp, crack or scale. The large volume of current said to be developed by these machines is sufficient, when the speed is high, to melt the anode.

Bausch & Lomb Optical Company, Rochester, N Y—Space 20

This exhibit will attract the physician who is scientifically inclined. The display of microscopes, microtomes, centrifuges, incubators, blood apparatus, etc., will be replete with interest. Some new and distinct models will be shown. The microscope to the modern physician is as necessary in diagnosis as the stethoscope. The centrifuge in urinalysis makes a microscopic examination possible in three minutes, which formerly required twenty or more hours.

Frank S Betz Company, Hammond, Ind—Spaces 64 and 65

In addition to a general display of surgical instruments, hospital appliances and electrical apparatus this firm will have as part of its exhibit a fifteen inch x ray coil and high frequency outfit combined. It also promises to have one of the finest exhibitions of surgical needles ever shown at a medical meeting. Besides these there will be shown several forms of lamps used in phototherapy. These will include the violet ray, the Linsen type and different kinds of incandescent outfits.

P Blakiston's Son & Company, Philadelphia—Space 19

What is said to be one of the most thorough works of its kind, *The Treatment of Disease* by Wilson will be displayed by this firm. This work which is just off the press is the latest word in treatment and therefore supplements any other. Practice the physician may have. Beck's *Surgical Diseases of the Chest* is another new book of this firm's which will be brought to the notice of visitors. A general display of its medical publications will, of course, be made.

Burroughs, Wellcome & Company, England—Space 40

This firm, which has recently opened a branch at 45 Lafayette Street, New York City, will exhibit a range of "Tabloid" and "Soloid" compressed drugs, etc. These preparations are claimed to be examples of unique accuracy of dosage and perfection of finish. Medical equipments of every description will be shown, fitted with medicaments suitable for all climates. These are exceedingly compact and can be carried in the pocket, in the carriage or motor car. Tabloid photographic chemicals for x ray work, compressed sterilized dressings and other interesting products will be on view.

Campbell Electric Company, Lynn, Mass—Space 16

The x ray and high frequency coil for which this firm claims such remarkable results will be on exhibit at its booth. Its simplicity, efficiency and the fact that it is always ready are a few of the qualities which the company wishes to demonstrate. The D'Arsonval and cautery attachment, with no interrupter to cause trouble and its two year guarantee will force this instrument on the attention of those physicians whose work requires such apparatus.

G W Carnrick, New York City—Space 25

This firm will display its products, trypogen and antithermoline, and will distribute a large supply of literature to physicians interested. The firm will also give a useful and appropriate souvenir to members of the Association. Visiting physicians will be cordially welcomed and inquiries relating to the products of this company will be answered by its representatives. Its product antithermoline will be exhibited in the new style glass container which is claimed to possess obvious advantages over the metal containers formerly used.

Clark & Roberts Company, Indianapolis, Ind—Space 33

A complete line of surgical furniture for physicians' offices and for hospitals will be the feature of this firm's exhibit. It is said to be especially high class, and all of the articles are designed for well equipped offices and hospitals. The goods are made in accordance with the latest scientific principles and designed for thorough asepsis. The firm places particular stress on the finish of its goods, great care being taken with the enamel so as to make it both durable and handsome.

Cleveland High Frequency Company, Cleveland, Ohio—Space 41

This company will show its high frequency machines which work independent of a coil or static outfit by simply plugging into any ordinary incandescent lamp socket. An expert on high frequency currents will be in charge of the exhibit, to go into the subject from a scientific standpoint with any inquiring physician. The increased interest in high frequency therapy will doubtless cause their expert to be kept busy.

G A Crayen & Company, New York City—Space 8

The Green Cross elastic Band of Braun is one of the specialties this firm will exhibit. This bandage which contains no rubber is a cotton product with a stretching capacity of 50 per cent. If after long usage it shows a slight loss in elasticity this property can be regained by cleansing it with soap and warm water. The Monachia wired plaster bandage will also be shown. This is claimed to possess the advantages of pliability, lightness, hardness and economy in use and to be excellently suited for making longitudinal plaster splints.

F A Davis Company, Philadelphia—Space 50

The exhibit of these well known medical publishers will contain several new publications of exceptional importance. Among them may be mentioned Fischer's *Diseases of Children* a volume of over 1000 pages profusely illustrated. Boer's *Diseases of the Stomach* translated by Bernheim a work of great practical value to all practitioners. Also Mendel's *Psychiatry* translated by Kraus which takes up this subject on new lines calculated to simplify the study of mental diseases. These standard works will doubtless attract the attention of visiting physicians.

Deimel Linen Mesh Company, New York City—Space 51

This company was incorporated in 1895 to exploit the fabric invented by Dr H L Deimel. Its exhibit will show all styles and weights of linen mesh underwear for men, women and children. By a special process of manufacture a soft, warm and porous fabric has been evolved called the "Im-Me". Since its introduction 12 years ago the product is claimed to have received the most friendly and grateful notice throughout the world. This exhibit will doubtless attract the attention of the physician.

DeVilbiss Manufacturing Company, Toledo, Ohio—Space 52

In treating diseases of the nose and throat the atomizer and nebulizer have each come to be recognized as a necessary part of the physician's armamentarium. This company will have on display in its booth the latest improved nebulizers and atomizers. Many of them are new and unique, and all of them of interest not only to the specialist, but to the general practitioner. It recommends the atomizer for making applications to the superior respiratory tract and the nebulizer for the applications to the inferior.

**Electro Surgical Instrument Company, Rochester, N. Y.
Space 46**

An interesting display of modern diagnostic instruments as well as of those appliances used in treatment will be given by this firm which manufactures electrically lighted instruments. Here will be found cystoscopes, urethroscopes, auroscopes, bronchoscopes, proctoscopes, specula, etc. The lamps in these instruments are said to be of low temperature and high illuminative power. All instruments of the tube pattern are supplied with the auxiliary chamber for the reception of the light carrier and lamp, a feature of importance.

Globe Manufacturing Company, Battle Creek, Mich.—Space 13

Electrically driven air pumps having among other special features double cylinders, compound compression, ball bearings, vacuum conversion, extra high power, automatic start and stop and automatic belt tightener will be one of the leading displays of this company. Its compressed air vibrator, which is adjustable for speed and length and force of stroke and gives direct impact and lateral movement, will also be shown. There will be in addition a complete line of nebulizer outfits, providing for vapor vibration and vapor massage.

E. J. Hart & Company, Ltd., New Orleans, La.—Space 66

The leading exhibit of this firm will be its preparation, *l'ac bismo*. This liquid is claimed to contain the hydrated oxide and subcarbonate of bismuth carried to the greatest possible degree of subdivision. For this reason its covering capacity is said to be many times greater than that of either the subcarbonate or subnitrate salt of the same metal. Explanatory literature will be distributed and the firm's representative will be present at the exhibit.

**Horlick's Malted Milk Company, Racine, Wis.—Spaces 26, 27
and 28**

The well and favorably known product of this firm will be on exhibit. To obtain milk produced under sanitary dairy conditions and as pure as scientific common sense would dictate is the object sought for and attained by this company. The hygienic dairying methods, as well as the superior malting of the grains in its own malt houses, have contributed largely, no doubt, to the success of Horlick's malted milk as a reliable, pure and nutritious diet for invalids and infants.

Hughes Halm Company, New York City—Spaces 11 and 12

This firm, which is the sole agent in New York and Philadelphia for the Allison office furniture, will also exhibit a line of instruments of its own manufacture. One of the most important of these will be the Bihlmaier vibrator. Several other specialties of more than ordinary interest that are handled exclusively by this company will contribute toward making its display one that will attract attention.

W. T. Keener & Company, Chicago—Space 49

A notable line of new medical books will be shown by this company. Among the most important will be found von Noorden's "Metabolism and Practical Medicine" in three volumes, and Green's "Encyclopedia and Dictionary of Medicine and Surgery." This encyclopedia, of which three volumes are now ready, will when complete consist of ten volumes. There will also be Morat's "Physiology of the Nervous System," Starling's "Recent Advances in the Physiology of Digestion" and a new edition of Yeo's "Manual of Treatment" adapted to the new Pharmacopeia. The exhibit will doubtless attract book-loving physicians.

Keystone Electric Company, Philadelphia—Space 18

This company, which manufactures "everything electrical," will give an exhibition of its high grade electrotherapeutic instruments. Wall cabinets, galvanic, faradic and cautery batteries will be shown in various styles. High frequency and x-ray apparatus, leucode-cent lamps and types of practically every kind of appliance used in electrotherapy will be displayed. The manager of the booth, Mr. Geiger, will have personal charge of the booth and will demonstrate the workings of all the apparatus.

Lea Brothers & Company, Philadelphia—Space 56

Medical literature will be well represented by this firm, the oldest medical publishers on the continent. Of interest to the profession will be the first volume of Osler's "Modern Medicine," a work to which the leading medical thinkers of the English speaking world have contributed. Even the oldest practitioner regards with affectionate interest Gray's "Anatomy," his first investment in medical literature, which this firm has now published for just half a century. The long list of practical works and medical text books will make the exhibit a Mecca for the studious.

Charles Lentz & Sons, Philadelphia—Space 54

The formaldehyd gas generator exhibited by this firm will prove to be of general interest. The heads of health departments are not alone concerned with methods of disinfecting, but the subject is a vital one to every general practitioner. This apparatus, therefore, which is claimed to be simple, efficient and durable as well as under the direct control of the operator, will interest many physicians. The firm will also have an exhibit of their surgical instruments and hospital supplies.

J. B. Lippincott Company, Philadelphia—Spaces 35 and 36

In addition to this firm's published line of excellent medical and pharmaceutical publications the attention of the medical profession will be called to several important books in active preparation. Among these books may be mentioned "Human Anatomy," by Piersol, and "Ortner's Treatment of Internal Disease," edited by Potter and translated by Bartlett. Also the "Diseases of Children," the American translation of which is edited by Shaw and Le Fetra, with an introduction by Holt, and "Roentgen Rays and Electrotherapeutics," by Kassabian. The new nineteenth edition of the United States Dispensatory, published May 1, will no doubt attract considerable attention.

Mellin's Food Company, Boston—Space 23

The preparation for the home modification of cow's milk, manufactured by this firm, will be on exhibit. Especial attention will be given to the demonstration by test tube experiments of the action of Mellin's Food on cow's milk. These will show how it inhibits the coagulation of the casein into the tough and indigestible curds which occasion the difficulty of digestion that is encountered so generally by the infant fed with cow's milk as commonly prepared.

E. B. Meyrowitz, New York City—Space 63

Various forms of x-ray and ophthalmologic apparatus will be displayed here. One of the more interesting will be the Priestly Smith Ward lamp, which has long and short focus lenses and uses a self-feeding candle as an illuminant. An ophthalmometer table which permits of accurate height adjustment, the Berger binocular loupe, lamp controllers, Holmgren's test worsteds, as well as eye, ear, nose and throat instruments, will make the exhibit one to attract the specialist in these lines.

**Modern Medicine Company, Battle Creek, Mich.
Spaces 9 and 10**

Here will be demonstrated therapeutic lamps of both the arc and Finsen type as well as the incandescent. An electric light bath cabinet will be in operation of the type originated and used at the Battle Creek Sanitarium. There will also be shown electric heating pads and electric blanket packs of this firm's make as well as other modern appliances such as sinusoidal apparatus, various vibratory machines, etc. The exhibit will be of interest to all physicians using the newer therapeutic agents.

V. Mueller & Company, Chicago—Space 61

This firm will show a line of first class surgical instruments. These will include those for the eye, ear, nose and throat specialist and for the special worker in genitourinary diseases, as well as those for the obstetrician and general surgeon. This company imports the famous Weiss knives as well as those of other first class makers. While making and selling a general line of surgical instruments it pays particular attention to the above specialties.

**Physicians' Supply Company of Philadelphia, Philadelphia.
Space 21**

Various types of sterilizers, nebulizers and centrifuges will be shown by this firm in addition to its exhibit of a complete line of high grade surgical instruments. To add to the inter-

SATURDAY, MAY 4, 1907

PERITONITIS AND THE ABSORPTION OF BACTERIA FROM THE PERITONEAL CAVITY

A series of experiments on the processes of absorption from the peritoneal cavity, by Dr B. H. Buxton,¹ have yielded results which are of great interest in connection with the problems of the treatment of peritonitis, supporting strongly the growing tendency of many surgeons to reduce intra-abdominal manipulations to a minimum. The favorable results of the semi-sitting posture, and the claimed disadvantages of peritoneal irrigation are also explained clearly by the observations on experimental animals. These experiments demonstrate the extreme rapidity with which bacteria injected into the peritoneal cavity are taken up, within five minutes they are found in the blood in great numbers, and in smaller numbers in the liver and spleen. Even greater numbers are found in the lymph nodes of the anterior mediastinum, which they reach from the diaphragm, where absorption occurs chiefly and most rapidly. A large number of bacteria are also entangled by a fibrinous exudate on the surface of the omentum, where many are taken up by phagocytes, while some enter the omental lymphatics and are absorbed by this route. However, there seems to be practically no absorption of bacteria by any other part of the peritoneum besides the diaphragm and the omentum, the parietal and visceral peritoneum and the mesentery do not seem to possess this function to any considerable degree.

When such an organism as the typhoid or colon bacillus is injected into the peritoneal cavity, even in very large numbers, the bacteria that enter the blood disappear again very rapidly, so that the greater proportion vanish in less than an hour, even in animals that subsequently die. This initial destruction of the bacteria seems to be due largely to the bactericidal power of the blood, and is nearly complete by the end of two hours, from two hours to six hours the number of bacteria increases somewhat, but from six hours up to forty-eight hours there is again a period of decrease which is probably due largely to phagocytes. Animals which die as a result of intraperitoneal injections of typhoid or colon bacilli succumb either about two hours after the injection, or else they survive for twenty-four hours or more, they seldom die during the interval be-

tween four and twenty-four hours. The reason for this seems to be as follows. The colon and typhoid bacilli contain a large amount of intracellular toxic materials (endotoxins) which are not liberated until the organisms are disintegrated. Consequently when an animal takes up a great quantity of these bacteria from the peritoneum and destroys nearly all of them within the space of an hour or so, an overwhelming dose of the poisonous intracellular toxins is liberated, and the animal succumbs at once, in spite of the fact that it has killed most of the bacteria that have been injected. In case the dose of endotoxins thus liberated is not fatal, the animal may recover, or may succumb to a later multiplication of the bacteria twenty-four hours or more after the injection. With the streptococcus the case is different, for this organism is not so rapidly destroyed after injection, and hence a primary overwhelming with endotoxins does not occur, as a result death does not follow until there has been time for an extensive multiplication of the cocci, after twenty-four hours or more.

It seems possible to apply these observations directly to the subject of the surgical treatment of peritonitis. First, we find that in acute peritonitis the danger is not so much from absorption of bacterial toxins, as from absorption of the bacteria themselves. The bacteria seem to enter the blood largely by way of the lymphatics, and they are absorbed chiefly through the lymph channels of the diaphragm, in this process omentum plays an important protective rôle by entangling bacteria and intercepting their passage toward the diaphragm. Absorption of bacteria occurs but little or not at all through the parietal, visceral and mesenteric peritoneum, hence the favorable outcome of peritonitis localized in the lower portion of the abdomen. In peritonitis following perforation, in which the chief organism is the colon bacillus or the typhoid bacillus, surgical intervention has sometimes been followed by death in a few hours, and this outcome has generally been ascribed to shock. Buxton suggests that in these cases death is really due to the entrance into the blood of large numbers of bacteria, which is decidedly favored by the disseminating forces of irrigation, and that instead of shock we really have an overwhelming intoxication with intracellular toxins liberated through the disintegration of the absorbed bacteria. Streptococcus peritonitis seems seldom to cause death in this way, the patient generally succumbing twenty-four or more hours after operation. Apparently, this organism reaches the circulation readily through generalizing infection, whether there is irrigation or not, but it is not rapidly destroyed, and hence there is no sudden intoxication with endotoxins. Later, after the cocci have multiplied greatly enough toxins will be liberated to cause death. In the case of colon or typhoid infection, if not enough bacteria enter the blood to cause fatal intoxication at once, the infection may either be successfully terminated, or the bacteria after a time may begin to multiply in the blood and tissues, with a resulting fatal intoxication after

¹ Jour. of Med. Research 1906 xv pp 388 and 1907 xvi pp 17-42

a period of two or more days. In any event, these experiments emphasize the importance of the measures which are now being so successfully adopted by many surgeons, the aim of which is to keep bacteria away from the diaphragm by means of posture and the avoidance of irrigation. Furthermore, it is to be remembered that pus is not exclusively a dangerous substance, its danger depends on the number and kind of bacteria it happens to contain, for the pus elements themselves are protective agents. To quote from Buxton "Pus in the cavity appears to the surgeon as something to be washed away, but it is precisely in the pus that there is protective action due to the innumerable phagocytes which it contains."

While Buxton's experiments support the attitude taken by those surgeons who oppose intraperitoneal meddling in general peritonitis beyond such measures as are necessary to remove the source of the infecting agent, yet it will be noted that they give a different explanation of the facts than has generally been adopted by the surgeons. The latter have considered that trauma of the peritoneal coat opens up avenues by which bacterial toxins enter the blood, whereas the animal experiments indicate that irrigation, sponging and similar measures are dangerous chiefly because they disseminate the bacteria so that large quantities can be taken up rapidly by the lymphatics of the diaphragm. This is particularly the case with peritonitis due to the colon-typhoid group of organisms.

IMPULSE, CRIME AND PUNISHMENT

It is now generally recognized that certain crimes are committed under the influence of impulses so strong as to be practically irresistible. The circumstances in which impulses become so strong have been much discussed. It is recognized that if a man has done irrational deeds early in life, that is, if he has performed serious acts entirely disproportionate to the motive urging him to their accomplishment, he is lacking somewhat in responsibility. If to this be added the fact that there is a nervous heredity, that is, that certain members of the family in previous generations have behaved irrationally especially in crises of conduct, then, in the opinion of many authorities, responsibility seems to be seriously impaired. These are practically the doctrines that the medical profession in the progress of its growing knowledge of mental diseases, has labored with no inconsiderable success, to graft on our criminal code, until now most murder trials have them brought to the fore to such an extent as to require expert testimony, and no criminal trial of importance occurs without at least some reference to insanity. At times, as in a recent noteworthy example, most of the attention of lawyers, judge, jury and above all the public is riveted on this aspect of the case. In so doing the medical profession has taken on itself great responsibility and it is well to view from a common sense standpoint

the consequences that may follow the application of these principles.

Anyone who has had any experience with those of diseased mentality is aware how cunning such people can be. Everyone knows how carefully men and women of distinctly lowered rationality may plan in order to secure some wished-for result. Many of the murders of keepers that occur in asylums are thought out beforehand with diabolical ingenuity in order to secure the hoped-for result. All who have had much to do with such people know, too, that practically the only thing which keeps many of them in proper submission is the deterring influence of punishment and the ignominy (for they have very acute feelings in such matters) that will come as the result of an unsuccessful attempt. In spite of the fact, then, that they are irrational and are ready to commit crime under the influence of practically uncontrollable impulse and without any proper reason, they are deterred from it by the thought of punishment and disgrace. In a word, though acting irrationally, they yet realize the nature of their act and, if punishment were certain to follow, would be deterred from it.

If we continue to loosen the claims of justice on all those who commit crime on impulse we shall lose those deterring influences of due condemnation and just punishment which are even greater over those of lowered mentality than over rational individuals. There are not many now who think that capital punishment is justified as a compensatory factor. Most persons consider that its deterring influence is the only reason for maintaining it. As a matter of fact, under the circumstances that surround many fatal crimes, responsibility is more or less impaired at the moment of commission. Men, however, put themselves in the conditions in which they know that such impairment may take place and are consequently responsible for their acts, though these may not be done with entire deliberate free will at the moment. If the present trend of medical opinion is not properly safeguarded in its diffusion among the public, many of those who are a little irrational and who are conscious of the fact that these irrationalities and certain hereditary traits may prove sufficient to keep them from capital punishment will be tempted to the commission of crimes by violence. There are many more people than is ordinarily imagined who are more or less irresponsible, who can not be taken care of by friends, nor committed to asylums. For them the deterrent effect of capital punishment or indefinite loss of liberty is society's only protection. This fact will have to be taken into consideration or we shall have a veritable epidemic of crime against human life (which seems indeed to be beginning) because of lack of punishment. Insanity ought not to prevent conviction for murder but the fact that it is a mitigating circumstance ought to change the punishment to confinement in an asylum.

Andrew D. White said not long since that human life is cheaper in this than in any other country in

the world except Sicily. The delays of justice and the many loopholes of our criminal procedure are responsible for this condition. Is it not possible also that the medical expert has added to it? At least we must be careful that all sides of this important question of responsibility be considered. It is better that ninety-nine guilty should escape than that one innocent man should be punished, but impulsive criminals are not innocent in the real sense of the term. The only motive that will keep many of them from cunningly taking advantage of the present trend of opinion is to maintain the sanction of law by properly meted out punishment, whether capital or not depends on circumstances, but with the stigma of a murder verdict properly to characterize the crime.

ROENTGEN RAY CASUALTIES

Examples attesting the dangers due to the unskillful use of the *x*-ray are becoming of rather disconcerting frequency. Here we read of the inhibition of muscular action, there of the appearance of indolent malodorous ulcers which take many months to heal. All will recall the fate of Dr. Weigel of Rochester, who was so injured during his experiments that first three fingers of his left hand had to be amputated, then his left hand, then his left arm at the elbow and later at the shoulder. Death, however, was inevitable.

The death of Wolfram C. Fuchs, of Chicago, on April 24, is the most recent in a dreadful series of disasters which must be attributed to the *x*-ray. Mr. Fuchs first became afflicted in 1905, and in the fall of that year the first joint of the right thumb was removed, from that time to his death he underwent five other operations, first for the removal of portions of the fingers of both hands, and later for a removal of the muscles of the right pectoral region. Other victims have been an assistant to Thomas A. Edison, a Boston colleague, and Bertha Fleischman, of San Francisco.

Pitkin¹ some time ago warned us against the destructive properties of the *x*-ray. Its effects are cumulative, the danger to the operator increases in a compound multiple ratio, with nearness to the tube, its size, hardness and degree of excitement, the number, frequency and duration of exposures, with physical conditions below par. The operator is apt to be injured without premonition. After a time the color of the hands and face changes, on this swelling ensues, then a few pruritic papules or pustules, with bran-like scales, or an "itching" warmth, local diaphoresis cutis anserinus and a glossy appearance of the parts, with edema. Muscular action becomes inhibited. Further exposure induces inflammation, disintegration, intense itching, with successive crops of papules, followed by a honeycombing of small, indolent ulcers which may become confluent with a sanious malodorous discharge. As

sequelæ may occur loss of skin, with the appendages, dreadful disfigurements—scars, pits and pigmentation—the loss of sebaceous and sweat glands, anesthesia, hyperesthesia to all forms of radiant energy, increased vasomotor activity, defective vision, and many other most unfortunate manifestations.

That Pitkin's warnings received not nearly the respect that ought to have been paid them was evidenced by the observations subsequently made by Brown and Osgood² in some eighteen cases of *x*-ray workers who had consulted them. These colleagues had been men in robust health, whose ages ranged from 22 to 40 years. Twelve of them had operated *x*-ray tubes from one-half to four hours at least thrice a week during the greater part of each year for from two to six years past. Six of them suffered more or less severe dermatitis of the hands. It was demonstrated, moreover, that the emanations from the tube are capable of affecting subdermal tissues without apparently affecting the skin itself. Brown and Osgood have found also that repeated prolonged exposure in an *x*-ray atmosphere produces sterility in the human subject. And this phenomenon has received repeated corroboration by Pitkin, Foersterling, Schmidt, Lassar, Geyser and others, who have found the *x*-rays destructive of embryonic life and who have not only sterilized by this means mature rabbits, guinea-pigs and fowls, but have also retarded the growth of the young. The destructibility of this agent when applied to seeds and grasses has been abundantly demonstrated.

The German Roentgen Society, meeting recently in Berlin, has recommended that the use of the *x*-ray be restricted to licensed practitioners. In any event the use of this agent should not be permitted the unscientific or the unscrupulous. Adequate protection to all parts of the patient's body not directly exposed for examination or treatment should be universally provided, else a perfectly just malpractice suit may be incurred.

The physician should learn from the many precautions now set forth in the literature for his benefit how to guard himself against the injurious effects of the *x*-ray, as well as to profit by "the beneficent effects of the force at which we have all marveled since Roentgen's discovery put into the hands of the medical profession this great aid to our diagnosis and gave impetus to the development of a valuable addition to our therapeutic measures."

THE ADVERTISING SWINDLER.

Opinion on any subject is largely dependent on the mental perspective. Only on such an assumption can we explain those incongruities of thought and action which we see daily. A case much to the point is exhibited in an editorial that appeared in a Chicago evening paper of recent date.¹ In referring to the aid given an unscrupulous but plausible advertiser by the press in sell-

¹ Pitkin (J. T.) Dangers of the *X* ray. *Virginia Med. Semi Mo.* Feb. 12, 1904.

² Brown (F. T.) and Osgood (A. T.) *X* rays and Sterility. *Amer. Jour. Surg.* April 1907.
¹ Chicago Daily News. April 16, 1907.

ing him advertising space in which to exploit his get-rich-quick schemes, the paper sums up as follows "It is an outrage for any newspaper to trade on the trustfulness of its readers in order to share in the profits of swindlers. Reputable patrons of newspapers should demand that they cease to be the beneficiaries of financial sharks through the acceptance of advertising which has fraud written all over it in the light of ordinary business judgment. A newspaper must be honest in its advertising columns as well as elsewhere in order to be really honest." The sentiments expressed are commendable, though—considering the case—somewhat trite, the policy outlined is praiseworthy—and likewise obvious. The incongruity of the thing becomes apparent when we glance through the advertising pages. The notorious "hypotheetical cocktail" Peruna, and the equally well-known alcoholic nostrum, Lydia Pinkham's Compound are found occupying conspicuous places. Mother's Friend, one of those damnable concoctions whose advertisers play on the feelings of dread uncertainty and fear that possess the expectant mother, is seen shouting its blatant warnings with scare headlines. Cures for drunkenness, cures for Bright's disease, cures for rheumatism and cures for epilepsy, each has its appointed place in this gallery of frauds. Must we conclude that the editor believes that "Bright's disease of many years standing" was "entirely cured with Warner's Safe Cure," that Golden Remedy "never fails to cure the worst cases of drunkenness," that S S S positively "cures skin diseases of every form"? Are we to understand that the editor honestly subscribes to all this? Editorial opinion would seem to oppose the idea that the same rule holds with this paper as obtains in some medical journals. To keep the editorial and advertising departments entirely distinct. But examination of the paper forces us to the conclusion that the business policy of the paper is not reflected in the editorial columns. Is it possible that the returns from fraudulent medical advertisements are sufficiently large to purchase immunity to criticism? This much at least is certain—so long as the paper continues to exploit such frauds, so long is it trading "on the trustfulness of its readers in order to share in the profits of swindlers." In giving space to these nostrums, advertising is accepted "which has fraud written all over it in the light of ordinary business judgment." As is said in another part of this same editorial, the "fact that a trusted newspaper permits him" (referring to the financial instead of the medical shark) "to do his lying under its auspices, convinces the credulous and they place"—not their savings, as in the case written of—but their health and lives "in his unscrupulous hands."

WHAT IS FEVER?

Various definitions of the febrile process have been given, but none is entirely satisfactory by reason of the incompleteness of our knowledge concerning the underlying mechanisms. Fever has been attributed to excessive oxidation but convincing demonstration is lacking that increased amounts of oxygen are constantly taken up by the body and increased amounts of carbon dioxide are constantly given off or that an increased amount of heat is generated or a deficient amount dissipated. That

fever and pyrexia are not one is generally recognized although the latter usually though not always accompanies the former. Dr. Woods Hutchinson¹ indulges in an interesting disquisition on this subject, expressing the view that the phenomena of fever appear to be due to a general disorganization and perversion of normal metabolism by toxins, with conversion of the energy ordinarily expended in secretion, growth, motion etc. into the waste product, heat. He holds that metabolism is less active during the febrile process than in health and that it is chiefly destructive instead of constructive. The resulting harm is due not so much to the elevation of temperature as to the action of toxic substances, which, if present in sufficiently large amounts or of a certain degree of virulence, may actually depress the temperature below the normal. When elevation of temperature does take place it may perhaps play the part of a secondary protective agency, affecting unfavorably the active pathogenic micro-organisms. In Hutchinson's opinion the "standard" of fever should be an increase in the daily range of temperature in excess of 1.5 degrees Fahrenheit.

THE ATLANTIC CITY SESSION

The fifty-eighth annual session of the American Medical Association will be held June 4 to 7 at Atlantic City, and we devote several pages this week to a description of that popular resort. The preliminary program of each session is also published, and a glance at the titles of the articles will show that a high grade of scientific work is in store for those who attend the meetings. This will make the third time that the Association has met at Atlantic City, and consequently a description of the town is hardly necessary for many of our readers. Since the last meeting there however, the membership of the Association has nearly doubled and in any event this seaside resort has so many attractions that its advantages will bear repetition. It is the ideal meeting place for the reason that it has ample hotel accommodations of a character to suit both those who want to pay but a moderate price as well as for those who desire all the luxuries. The railroad rates this year are very low—practically one fare for the round trip—but what is of special advantage is the fact that the time limit is longer than on former occasions. As will be noticed by a reference to the paragraph on railroad rates, members may get an extension to June 18. This will give an opportunity to utilize the clinics, etc., that are to be given in Philadelphia during the week following the Association session, to recuperate on the seashore or to enjoy a side trip to the famous eastern metropolis New York or to the Jamestown Exposition perhaps by a delightful boat trip on the picturesque Chesapeake Bay or to stop for a few days in the Nation's Capital. The Atlantic City people are making as elaborate preparations as were made at any former session and they are evidently determined to make the visit of the members of the Association an agreeable one. While it is impossible to prophesy so early the present indications are that the attendance at the coming session will equal if it does not exceed that of last year at Boston.

Medical News

ALABAMA

Medical Journal Company Incorporated—The Alabama Medical Journal Company has been incorporated at Birmingham with a capital stock of \$3,000. The company has purchased the *Alabama Medical Journal* from the estate of the late Dr. John C. LeGrande, and intends to continue the publication of the journal.

Personal—Dr. Willis W. Scales, Mobile, has been appointed assistant surgeon in the United States Public Health and Marine Hospital Service. The following staff of the Mobile City Hospital is announced: Surgeons, Drs. William McD. Mastin, George E. Gavin, Douglas G. Campbell and William G. Ward, physicians, Drs. Joseph Schwartz, Ernest S. Feagin, James J. Peterson and Nicholas A. Madler, obstetrician, Dr. Percy J. Howard, pathologist, Dr. Neal E. Sellers, and dermatologist, Dr. M. Toulmin Gaines.

CONNECTICUT

Venerable Practitioners—Dr. Ralph J. Griswold, Greenwich, will celebrate the fiftieth anniversary of his entry into the practice of medicine, April 15.—Dr. Gurdon W. Russell, Hartford, for many years medical director of the Aetna Life Insurance Company, celebrated his ninety-second birthday anniversary, April 10.

Vital Statistics—The vital statistics of Connecticut for 1905, about to be published, shows that 23,271 births were recorded in the year, an increase of 407 over the previous year, and the highest number ever recorded. The number of marriages recorded was 8,075, or 440 more than for the previous year. There were 16,208 deaths, or 164 per 1,000, which is a slight increase as compared with the previous year.

DISTRICT OF COLUMBIA.

Personal—Dr. Luther H. Reichelderfer, superintendent of the Garfield Memorial Hospital for seven years, has resigned to enter private practice, and has been succeeded by Dr. Wayne F. Cowan.—Dr. Eugene L. LeMerle has been appointed by the commissioners medical inspector in the contagious disease service, vice Dr. C. Norman Howard, resigned.

New York Milk Barred—The Department of Health of the District of Columbia, in its battle for the certification of all milk, has rejected the permits of certain New York shippers and considers the ordinance at present before the Board of Aldermen in New York City as mild in its requirements as compared with regulations in the District of Columbia. The District also declares that cows imported from the Empire State are more generally affected with tuberculosis than are those from other states farther south.

ILLINOIS

Personal—Dr. Edward Hassen, Peoria, has been appointed a member of the local Board of Pension Commissioners, vice Dr. Alvin N. Keith, resigned.—Dr. Downing D. Nice and family, Bowen, will leave in a few weeks for their new home in California.—Dr. and Mrs. Hiram E. Johnson, Fairbury, have returned from Crescent City, Fla., where they spent the winter.

State Society Meeting—The annual meeting of the Illinois State Medical Society will be held in Rockford May 21 to 23. The local committee announces that the places for holding meetings will be within one block of the principal street of the city and within three blocks of all the hotels. The general session and sessions of sections will be in the Church of the Christian Union and the House of Delegates and committees will meet in the Soldiers' and Sailors' Memorial Hall. A novel feature of the scientific portion of the meeting is the joint sessions of the medical and surgical sections. A part of the section is to be devoted to medicine, another part to surgery and a third to borderland topics. On Wednesday night a banquet is to be given at which special honor is to be paid to Drs. John H. Hollister, Chicago, and F. O. Ensign, Rutland, who celebrate the fiftieth anniversary of their membership in the society.

Chicago

Scarlet Fever Spreads—Scarlet fever is reported to be prevalent and threatens to become epidemic in South Chicago.

Personal—Dr. and Mrs. Daniel R. Brower have returned from a trip to Egypt and Palestine.—Dr. and Mrs. Clifford C. Cruikshank sailed for Europe April 27.

Auto Run to Rockford—It is reported that 50 physicians of the city expect to participate in an automobile run from Chicago to Rockford, May 20.

Emergency Inspectors Discharged—The 259 employees of the health office, whose services were secured during the recent scarlet fever epidemic, have been discharged on the expiration of the period for which they were engaged.

X-Ray Expert Dies—Wolfram C. Fuchs, one of the earliest and best known exponents of the Roentgen ray, died at his home in Chicago, April 24, from cancer, said to have been due to prolonged exposure of the Roentgen rays. Mr. Fuchs was an electrical engineer, but became interested in the X-ray treatment of disease when Roentgen's researches were first published, and was one of the first in Chicago to use this method of treatment and to take X-ray photographs.

Deaths of the Week—The deaths for the week ended April 27 were 678, or 61 more than for the preceding week, the respective annual death rates being 16.77 and 16.26 per 1,000. Of the chief death causes, pneumonia was responsible for 118 deaths, heart disease for 63, consumption for 55, Bright's disease for 43, violence, including suicide, for 39, and acute intestinal diseases and cancer, each for 30. Scarlet fever caused 17 deaths, diphtheria 13, influenza 7, whooping cough 6, measles 5 and typhoid fever 3.

The New Health Commissioner's Creed—In the first communication of Health Commissioner Evans he addresses his co-workers as follows:

If we succeed it will be due to three factors:

1 The efforts of Drs. Whalen Reynolds and their predecessors who have increased the efficiency of the department year by year until it has reached its present position. I wish sincerely to acknowledge our debt to them.

2 The support of the men of the department.

I must have their help not only in matters of routine, but in planning and managing and in solving great community problems. It must be our department.

3 We must have the support of the people and the press.

MARYLAND

Site for Sanatorium Bought—The Maryland Tuberculosis Sanatorium has purchased, for \$10,000, 192 acres at Sabillasville, as a site for a tuberculosis sanatorium.

School Rooms for Epileptics—A canvass of the public schools of Baltimore shows that there are 51 children suffering from epilepsy. The school board has decided to establish two or three special classes for epileptic children, beginning with the next school year.

Society Meeting—At the annual meeting of the Montgomery County Medical Society, held in Rockville, April 16, Dr. James E. Deets, Clarksburg, was elected president, Dr. Charles Farquhar, Olney, vice president, Dr. John L. Lewis, Bethesda, secretary and treasurer, and Dr. Horace B. Haddox, Gaithersburg, censor.

Personal—Dr. Montgomery E. Higgins, Boyds, has returned from Panama, and expects to leave this month for Europe.—Dr. Frederick H. Baetjer, assistant in actinography at Johns Hopkins Hospital, Baltimore, was operated on for appendicitis, April 19.—Dr. Charles G. McGill, Catonsville, is reported to be critically ill.—Dr. L. Gibbons Smart has leased a house with 11 acres of land, near Lutherville, for a private sanitarium.—Dr. Henry V. Hodgson has been elected president of the Lonaconing Club.

Tuberculosis Sanatorium—About 200 acres of land in Frederick County, near Blue Ridge Summit, has been purchased for the Maryland Tuberculosis Sanatorium. The site is 1,500 feet above sea level and the buildings are already in process of construction. Accommodation will at first be secured for about 75 patients. At present, \$90,000 is available for the institution, but it is hoped that \$150,000 may be appropriated to complete the buildings and to increase the annual appropriations for maintenance from \$15,000 to \$20,000.

Baltimore

Measles Prevalent—During the week ended April 13 there were 105 cases of measles reported with 5 deaths, as against 10 cases in the corresponding week of last year.

Personal—Dr. Henry Barton Jacobs has been elected a member of the Maryland Tuberculosis Commission.—Dr. Ira Remsen of Johns Hopkins University was elected president of the National Academy of Sciences at its meeting in Washington April 17.—Dr. Roland B. Whitridge has gone to Europe for several months.

Hospital for Hebrew Consumptives—Mr. Jacob Epstein has given \$25,000 toward the establishment of a hospital for Hebrew consumptives with the understanding that the management of the institution shall be assumed by the Federated

Jewish Charities Four individuals have offered \$500 annually toward the maintenance of the hospital, and a special committee has been appointed to consider ways and means

MASSACHUSETTS

Diphtheria—An outbreak of diphtheria is reported at Milton and Dorchester Lower Mills, where more than 50 cases have been reported, with two deaths

Fitchburg in Line—Fitchburg has organized an association for the prevention and cure of tuberculosis, and among its officers are Drs Frederick H Thompson, Cordelia M Whittier and Herbert J Wallace

Medical Library Committee—A committee consisting of Drs Walter H Chapin, Walter R. Weiser and James B Comins has been appointed to confer with the physicians and medical societies of Springfield, to determine what amount the physicians of the city will agree to give annually per capita for the support of a medical library

Personal—Dr Thomas J Scanlan, Dorchester, Boston, has been nominated as physician of the fire department—Mr Alexander M Wilson, Boston, who has been superintendent of the Massachusetts Association for the Relief and Control of Tuberculosis, has resigned, to take charge of the Chicago Tuberculosis Institute, and will take up his work there June 1—Dr Edmond A Babin, Haverhill, was seriously injured in a runaway accident, April 18—Dr Willis L. Tucker has been appointed town physician of Hinsdale—Dr James J McDevitt, East Boston, has been appointed deputy health commissioner—Dr James R. Berwick, Methuen, has been re-elected town physician—Dr Albert Taft has been removed from his position as resident physician at the Penal Institutions, Deer Island

MISSOURI

Graduation—The annual commencement exercises of the St. Louis College of Physicians and Surgeons were held April 26. Dr Waldo Briggs, dean of the college, conferred the degrees and Dr Otto Sutter delivered the faculty address

Hospital Notes—The Board of Directors of Provident Hospital, which was established twelve years ago by a number of physicians and citizens for the care and treatment of colored patients, is endeavoring to raise \$25,000 to purchase a suitable site on which a permanent hospital building may be erected

Hodgen Memorial Meeting—At the meeting held under the auspices of the St. Louis Medical Society of Missouri, April 27, to commemorate the twenty fifth anniversary of the death of Dr John T. Hodgen, Drs John C Morfit, president of the society, and Warren B Outten chairman of the committee of arrangements, jointly presided. A life size oil painting of Dr Hodgen occupied a conspicuous place on the stage. Dr Joseph M Mathews, Louisville, who spoke on "Dr Hodgen as a National and International Figure in Medicine," eloquently compared him to Lincoln and Daniel Drake and asked the question whether the spirit of self sacrifice of the public weal, of intense thought and application which distinguished Dr Hodgen, fills the lives of the practitioners of to day and whether men have not now become so imbued with the spirit of the present times that they allow other things than sturdy accomplishments, honest motives and high principles to actuate them. He advocated that a tablet to Dr Hodgen's memory be placed in the "Hall of Fame." Dr Warren B Outten, St. Louis, who spoke on "The Educational Influence of Dr Hodgen in the Mississippi Valley" told how his students revered him, and how marked his influence had been on the profession of the West. Dr Charles H Wallace, St. Joseph, president of the Missouri State Medical Association who bore witness to "The Debt of Missouri to His Example and Memory," spoke of the benefit to the human race of Dr Hodgen's skill and learning. Hodgen he said was one of the great men of the age. Hon Charles Nagel, St. Louis paid an eloquent tribute to "His Worth as a Citizen." Rarely he said were such forces of mind and fundamental principles of character united in one man. He was a universal man not too great for any one profession but great enough for any one to make it redound to the benefit of the human race. He was essentially an American citizen and in everything he did there was the all pervading influence of the citizen and the man. Dr Henry C Fairbrother, East St. Louis Ill. to whom was assigned "His Power and Influence as a Teacher Over His Classes" referred to Dr Hodgen as the George Washington of the medical profession. He was beloved and revered by his students each of whom felt that in him his professor took an especial and personal interest. Dr Le Grand Atwood, Ferguson, Mo. who was a fellow student and roommate of Dr

Hodgen, spoke on "His Student and Social Life," and narrated many reminiscences of the student life of the great surgeon. He was a physical and mental giant and exhibited all the virtues and excellencies that go to make up the real man. Dr Charles D Stevens, St. Louis secretary of the committee of arrangements, then read letters of regret from physicians who were unable to be present, but added their tribute to the memory of Dr Hodgen.

NEW YORK

To Defeat Optometry Bill—The Medical Society of the County of New York has sent a letter to its members asking them to use personal influence with their representatives in order to secure the defeat of a bill regulating the practice of optometry which makes partial doctors of opticians. This bill passed the Assembly April 23. It would create a new profession, and make an entering wedge for the making of specialists of men who are not qualified by education or training for the work which the bill authorizes them to do. If this bill became a law other bills might follow creating separate professions for makers of orthopedic apparatus, trusses etc. and for vibrationists and others so that the profession would consist of divisions of practitioners imperfectly educated and trained and licensed to practice under separate laws, which would not be advantageous to the public or to the medical profession.

New York City

Personal—Dr Marcus E Peterson, Brooklyn was thrown from his carriage and seriously bruised in a collision with an automobile, April 18—Dr Joseph F. Todd, Brooklyn has been appointed attending gynecologist to St. Peter's Hospital, Brooklyn—Dr Arthur R. Eddy, Manhattan, has been appointed assistant surgeon N. G. N. Y., and assigned to the Seventy first Infantry.

Many Smoke Protests—The Anti Smoke League obtained a conviction against the New York Edison Company on April 22, and since that time numerous complaints have been pouring in from all over the city calling attention to the violation of the sanitary code in the use of soft coal. The disposition of small offenders is to adopt means of preventing smoke where soft coal is used, and it is possible to adjust furnaces to such methods.

New Clinical Society—The medical staff of the New York Throat, Nose and Lung Hospital has organized a society known as the Clinical Society of the Hospital. Members and ex members of the staff are eligible to membership. The officers are as follows: President, Dr Elmer A. Miller, vice president, Dr Sam Goldstein, secretary, Dr Charles F. Walter, treasurer, Dr M. C. Tracy, hospital committee, Drs Stephen D. Harrison, James J. Concannon and M. I. Schamberg, and scientific committee, Drs Samuel J. Kopetzky, F. R. Kemple and John A. MacIsaac.

The Mosquito Doomed—Dr Abrahm H. Doty, health officer of the Port of New York, says that he will make good his promise of five or six years ago that at this time Staten Island would be practically free from the salt water mosquito. He began the work in 1900. The only way in which the work could be done was by draining. At first much opposition was encountered but the system of drainage has resulted in reclaiming much land that was formerly valueless. Dr Doty intends to turn his attention to the study of the different varieties of mosquitoes of New York and vicinity, and expects to find that much disease is transmitted through this agency.

Aid for Hospitals—The funds raised by the Saturday Hospital and Sunday Association amounted to \$103,110 of which \$1,515 was derived from the offer of Mr and Mrs James Speyer to duplicate all gifts after \$100,000 had been raised. The allotment was made to hospitals on the basis of free work done. The Montefiore Home and Hospital and Mount Sinai Hospital received the largest awards \$8,400 each. St. Luke's Hospital received \$4,647. Roosevelt Hospital \$4,427. German Hospital \$4,119. Lebanon Hospital \$4,074. Hospital for the Ruptured and Crippled \$3,673. Postgraduate Hospital \$3,504. New York Infant Hospital \$2,499. Society for Living \$2,295. Orthopedic Dispensary and Hospital \$2,104. St. Mary's Free Hospital for Children \$2,942 and others received lesser amounts. The Presbyterian Hospital will receive between \$120,000 and \$1,000,000 by the will of the late Peter Cumming.

NORTH CAROLINA

College Commencement—The fifteenth annual commencement of the North Carolina Medical College was held at Charlotte April 16 when a large number of graduates were present. The address to the graduates was made by Dr. J. B. Estlin.

Pressly, Augusta, Ga. The new building of the college, which was erected at a cost of \$30,000, was opened to the public on this occasion for the first time.

Personal.—Dr Thomas Stringfield, Waynesville, has been appointed inspector general of the North Carolina National Guard, with the rank of colonel.—Dr Charles B Woodley, Kinston, has been elected supreme ruler of the Fraternal Mystic Circle.—Dr Gaillard S Tennent, Asheville, has gone to Baltimore for six weeks' postgraduate work.—Dr William H. Cobb, Goldsboro, is taking postgraduate work in the University of Pennsylvania laboratories, Philadelphia.—Dr Henry F Long, Statesville, is building an addition to the Long Sanatorium to accommodate ten additional patients.

OHIO

Newspaper Notices.—The Marion County Medical Society, at its last meeting, passed resolutions forbidding the members of the society to give items to newspapers regarding cases in which they are interested.

Graduate Course.—A course of lectures, laboratory work and clinics for graduates at the Medical College of Ohio, Medical Department of the University of Cincinnati, is announced to begin April 15 and to continue until June 1.

Elections.—At the semi-annual election of officers of the Association of Assistant Physicians of Ohio State Hospitals, Dr Earl E Garver, Columbus, was elected president, Dr Frank Day Ferneau, Toledo, vice president, and Dr Isabelle A Bradley, Columbus, secretary.—The Second Councilor District Medical Society, at its annual meeting, held in Springfield, April 11, elected the following officers: Dr J Robert Caywood, Piqua, president, the presidents of the various constituent societies, vice presidents, Dr Asa C Messenger, Xenia, secretary, and Dr Webster S Smith, Dayton, treasurer.

PENNSYLVANIA

Spotted Fever in Pittsburg.—Anxiety is felt in Pittsburg on account of the prevalence of cerebrospinal meningitis. During March and April 17 cases occurred, with 11 deaths.

Personal.—Dr Charles D Schaeffer has been elected mayor of Allentown, vice Dr Alfred J Yost, deceased.—Dr Gaetano Conti, Pittsburg, is to be the guest of honor at a banquet given by the Italians of the city, May 8.

Philadelphia.

Personal.—Dr DeForest Willard, who has been ill for a year, has returned from the South greatly improved in health and has resumed professional work.—Dr John B Deaver has been appointed consulting surgeon to the Philadelphia Hospital, vice Dr John H. Brinton, deceased.—Dr George M Piersoll, chief resident physician at the University Hospital, was given a banquet by the physicians and nurses of the hospital at which he was presented with a silver loving cup. He is soon to go abroad.

RHODE ISLAND

Gives Hospital.—Mrs Ann Crawford Allen Brown has presented the estate of her late husband at Quiddesset, to the Rhode Island Hospital, to be used as a hospital for children afflicted with tuberculosis of bones. The gift is in memory of the late Crawford Allen, and comprises a large brick residence and 100 acres of land.

Tuberculosis Exhibit.—The traveling tuberculosis exhibit was opened in Providence during the week of March 18. It included both the exhibition of the National Association for the Study and Prevention of Tuberculosis and that of the Boston Association for the Relief and Control of Tuberculosis, together with exhibits from Rhode Island institutions.

Personal.—Dr Maude A E Kenney, Providence, was brutally assaulted in her father's residence by a burglar, recently.—Dr Henry J Hoye, Providence, was seriously injured by the fall of a counterweight, used to grip cars on the College Hill incline. His face and hands were badly lacerated.—Dr E T Hoffman, formerly interne at the Good Samaritan Hospital, Providence, has been appointed receiving physician at the City Hospital, Cleveland, Ohio.

GENERAL

Delegates to Red Cross Meeting.—Surgeon General Robert M O'Reilly, U S Army and Medical Director John C Wies, U S Navy, have been selected as delegates from the American Red Cross Society to the International Red Cross meeting in London.

CANADA.

Another Fire at McGill University.—A second fire has occurred at this university within a few weeks. This time the

fine four story building of the medical faculty has been totally destroyed. Dr F J Shepherd, professor of anatomy, has lost his anatomic museum, Dr Ruttan, professor of chemistry, all his private library which he kept in the building, Dr J George Adams, professor of pathology, nearly all his pathologic museum and his private library which he kept in the building for the benefit of the students. The latest report states that he managed to save the manuscript of a new work on pathology on which he has been working for many years. Among the many fine pathologic specimens which had been collected by McGill none was finer than the collection of calculi, in fact, it was said to be the finest in the world. The Osler collection was also entirely destroyed. These specimens Dr Osler collected while he was pathologist to the Montreal General Hospital. The main building of the Medical Faculty of McGill was erected in 1873. Large additions and alterations were made in 1885 and again in 1893. It was at this time that Lord Strathcona endowed the chairs of pathology and public health with \$100,000. Six years after he again contributed \$100,000 for the development and extension of the museums, laboratories and library. The latter contained 24,000 volumes and was completely destroyed. This is the seventy fifth session of McGill, and the students enrolled in the medical department numbered over 400. Coming so quickly on the destruction of the engineering building, incendiarism is suspected and an investigation is proceeding.

FOREIGN

Poltzer's Retirement.—At the end of the summer term, 1907, Prof A. Poltzer will have arrived at the age beyond which, according to the laws of Austria, he may not retain his chair at the University of Vienna. He will therefore resign this position, as well as that of the head of the Vienna ear clinic. The lectures which he has delivered for the past forty six years will cease. A formal celebration had been planned, but Professor Poltzer requested that in view of the fact that a number of deaths had occurred in his immediate family, no public celebration take place. Dr Hugo Frey, Vienna, informs us that it has been decided to present to Professor Poltzer a gold medal bearing his portrait made by a renowned sculptor. Copies of this medal, some in silver and others in bronze, will also be struck off to serve as souvenirs. These will be disposed of at \$5 and \$250 each, respectively, and the names and addresses of all subscribers will be presented with the gold medal and address to Professor Poltzer. Dr D Kaufmann, Vienna, vi, Mariahilferstrasse 37, will receive all communications and remittances. Any surplus there may be will be put at Professor Poltzer's disposal as a fund to further some scientific object.

Thirty sixth Congress of German Society for Surgery.—As mentioned elsewhere, this congress was held at Berlin, April 3-6, and Rehn opened the proceedings with a summary of what has been accomplished with surgery of the heart since he first attempted it in 1897. He does not approve of cutting a large flap for access, and stated that by temporary compression of the veins with the fingers the suture can be done on the practically empty heart. Riedel and Kümmell reported that exposure of the heart and direct massage had not proved successful in their hands in resuscitating patients in "chloroform death." The momentary effect was remarkable, but actual life was not restored. Küttner related the clinical cure of a patient with leukemic wandering spleen treated by splenectomy, and Bakes an interesting case of hour glass stomach treated by gastroenterostomy in each half of the stomach, the implanted loops uniting as they entered the intestine below. The second session was devoted mainly to operative treatment of pulmonary affections. A number of surgeons described favorable experiences with surgery of the lungs, some spoke of experimental research with the Sauerbruch under pressure cabinet. Lenhartz reported 85 cases of gangrene of the lung in which he had operated. In 53 cases the patients were cured, as also in 4 out of 5 cases of abscess. In 20 cases of carcinoma of the lung—diagnosed mainly by the presence of fat granules in the sputa—he operated in 4 instances and one of the patients is clinically cured for the time being. Körte stated that he had lost 3 patients in collapse in operating on the lungs. Garré recommends displacement of the lung and pneumolysis to allow the lung to retract and bronchiectasia to subside. The speakers did not seem to consider the Sauerbruch air cabinet indispensable for operating on the lungs. Küttner and Wendel attempted to operate on the esophagus under over pressure but both patients succumbed. Kümmell reported 4 deaths in 10 prostatectomies and Völkers a mortality of 9.7 per cent in 32 perineal prostatectomies and 2 deaths in 7 transvesical operations. Rumpel called attention to the psychic disturbances some

times observed after removal of the entire prostate, in many cases leading to suicide. For these reasons Rovsing avoids prostatectomy whenever possible, and prefers cystostomy with a special catheter left permanently in place. The discussion seemed to show that the transvesical route is coming to be regarded as the easiest and least dangerous. Rovsing reported successful removal of the entire bladder with implantation of the ureters in the groin with receptacles worn to collect the urine, which have proved very satisfactory. Jacoby exhibited a stereoscope with which the interior of the bladder can be inspected. Hoffmann described what he calls "suprahyoid pharyngotomy," a transverse incision for access to a tumor in the nasopharynx. Haberer reported implantation of kidney tissue, but without definite results. Bockenheimer stated that he has noticed that wounds infected with tetanus did not lead to tetanus if they were treated with a salve and Peruvian balsam. He advocates, therefore, the application of antitetanus serum directly to the wound in the form of a salve. Our German and French exchanges for April contain more or less detailed accounts of the congress and of the orthopedic and Roentgen congresses just preceding. They mention the presence of Dr. Keen as guest of honor. The official transactions of the surgical congress are published in a special issue of the *Centrbl f Chirurgie*, generally in July.

Pharmacology

ANASARCIN AND ANEDEMINE

Reports of the Council on Pharmacy and Chemistry and Comments Thereon

The following reports were submitted to the Council by the subcommittee to which these articles were assigned:

ANASARCIN

To the Council on Pharmacy and Chemistry—Your subcommittee to whom Anasarcin (Anasarcin Chemical Co., Winchester, Tenn.) was assigned, herewith submits its report.

This remedy is offered in two forms: "Anasarcin Tablets," a pretended combination of the active principles of oxydendron arboreum sambucus canadensis, and uirginea scilla, and "Anasarcin Elixir," said to contain the active principles of oxydendron, sambucus, hepatica and potassium nitrate. The advertisements of these articles conflict with the rules of the Council as follows:

With Rules 1 and 2. The composition of these articles is kept secret in that the proportion of the ingredients is not furnished. The statement that it contains the "active principles" is misleading, since these are for the most part unknown.

With Rule 6. The description of the pharmacologic action of Anasarcin agrees practically with that of squill. No material part of its effects can be attributed to the other ingredients. Nevertheless the advertisement studiously cultivates the impression that Anasarcin has no relation whatever to the digitalis group in which scilla is commonly placed. The claims are therefore misleading. The claim of its infinite superiority to digitalis, the claims that it cures neurasthenia eliminates uric acid in rheumatism and is useful in obesity, cystitis, lumbago and eclampsia dyspepsia and asthma, and that it works wonders in exophthalmic goiter, appear exaggerated or false.

The recommendation of its indiscriminate use in nephritis for lowering the blood pressure and the statement (contradicted in the firm's own literature) that it is not depressing are actually dangerous.

It is recommended that the articles be refused recognition and that the report with explanations be published.

ANEDEMINE

To the Council—Your subcommittee to whom Anedemin (Anedemin Chemical Co., Winchester, Tenn.) was assigned herewith submits its report.

Anedemin is an evident imitation of Anasarcin. It is marketed as tablets said to contain the isolated active principle of *straphanthus apocynum*, squill and sambucus—chemically combined. The quantities are not stated. The therapeutic claims are copied

almost literally from the Anasarcin circulars and are equally false. Anedemin, therefore, conflicts with Rules 1, 5, 6 and 7.

It is recommended that this report be published with comments.

The reports were adopted by the Council and are herewith published.

W. A. PUCKNER, Secretary

REMARKS ON ANASARCIN AND ANEDEMINE

ANASARCIN

This wonderful remedy, Anasarcin, has already been exposed in these columns (vol. xlvii, p. 288), but it deserves additional mention, as it teaches several important lessons of general application. It is a typical example of the revival, under a new name and a thin disguise, of an old, time-worn article, squill, the use of which in dropsy has been practically discarded, presumably because experience has demonstrated its general inferiority to other drugs. Anasarcin further illustrates the dangers involved in the use of semi-secret nostrums. It also shows how a short experience with a widely advertised but little understood drug is apt to lead to conclusions which more extensive experience demonstrates to be entirely fallacious.

The first lesson is, that formulas are not always what they seem. A hasty glance at the formula of Anasarcin tablets, the basis of the Anasarcin dropsy cure, creates the impression that it is a non-secret remedy, for it is said to represent a combination of the active principles of oxydendron sambucus and scilla. As a matter of fact, it is a secret nostrum of the insidious kind. A formula which omits the quantities of its potent ingredients means very little. Further than this, we do not hesitate to charge that the claimed composition is a deliberate deception. The circulars emphasize the claim that Anasarcin consists of the isolated principles, and not of the crude drugs. Now, the isolated active principles of sambucus and oxydendron are not on the market, for the good and sufficient reason that no active principles have ever been isolated. Are we to believe that the Anasarcin Company has surpassed the accredited chemists and has discovered such principles and is isolating them? We shall have more to say on this subject presently, but any one in the least familiar with the difficulties attending the isolation of organic principles knows such an idea to be preposterous. Indeed, it is absolutely incompatible with the exhibition of ignorance of the elementary facts of pharmaceutical chemistry which is given by these people when they call the active principles of digitalis and squill "alkaloids."

It is an axiom that the effects of a mixture can only be understood if the actions of its components are known. So far as we know, the physiologic effects of oxydendron and sambucus have never been scientifically investigated for the simple reason that they are too slight and indefinite to promise results. Both are credited with some slight obscure diuretic action. Oxydendron, the sour wood or sorrel tree, is a small tree of the heath family, the acid leaves of which are said to be chewed by hunters for their pleasant taste and for the relief of thirst. Sambucus is the common elder. It is most unlikely that these two innocuous substances should play any part in the claimed powerful effect of Anasarcin; they are evidently put in the formula we do not say in the preparation to obscure the fact that Anasarcin is composed principally of squill. That this is so can be gathered unmistakably from a study of the pharmacologic action of Anasarcin as described by its promoters.

Acting primarily on the heart and arterial system through the nerve ganglia, a natural physiologic balance is established between the arterial and venous systems, whereby effusions are eliminated. Coincident with this action there is a powerful slowing of the pulse. If the remedy is pushed, the heart is brought down to 20 or 30 beats per minute. Its physiologic action is to stimulate the cardiac motor ganglia through the cardiac plexus of the sympathetic system and at the same time exert an inhibitory influence upon the cardiac fibers of the parasympathetic system, thereby dilating the arteries, lowering the heart action and increasing the force of the systole. The powerful diastolic action allows the ventricle time to completely fill and the powerful contraction causes the mitral valve to close more tightly and at the same time increases pressure in the arteries, serving thereby the double purpose of relieving congestion and increasing heart action. Anasarcin will raise the blood pressure.

To appreciate fully the meaning of this description of the actions of Anasarcin, it should be compared with the effects of the digitalis group, to which squill belongs. The following account is quoted literally from a recent Text Book of Pharmacology (Sollmann)

The phenomena of the therapeutic stage of digitalis action are said to be

1. Slowing of the heart with systole and diastole both lengthened
 2. Increased strength of beat, leading to greater efficiency of the individual contractions and to an increase in the total efficiency
 3. A tendency to the systolic phase.
 4. A rise of blood pressure due mainly to the increased action of the heart out partly also to a vasoconstriction
- Abnormal dilation of the heart is lessened and irregularities tend to disappear

The therapeutic effects are explained, in part, as follows

A larger amount of blood will be thrown into the aorta and coronary circulation. The first effect will be an improved condition of the heart. The tonic action narrows the ring of the valves brings them closer together narrows the orifice. The venous congestion will tend to be relieved. This relief will fall in the first place on the lungs. The lowering of the venous pressure will tend to cause absorption of the effusions

The nauseant action of squill, which is alluded to in connection with Anasarcin, is too well known to require more than a mention

In brief, then, it appears from the statements of the Anasarcin Company that the action of the remedy is that of squill and that the other ingredients are a mere blind. It is, of course, well known that squill can be used as a substitute for digitalis in cardiac dropsy, although it is generally considered very inferior to the latter drug. Rose Bradford, for instance, states "Squill is not used to any extent in the treatment of cardiac disease and cardiac dropsy, digitalis being a far more efficient and less toxic substance." However, it has been frequently observed that digitalis occasionally fails, and it may then be replaced successfully by another member of the group. At all events, it is very likely that squill is a fairly efficient substitute for digitalis, especially when it is supplemented by a very free course of Epsom salts and by potassium nitrate (the active ingredient of Anasarcin Elvir), both of which are stated to be essential adjuvants to the Anasarcin (or squill) tablets. There can be no objection to the use of squill when it is indicated, but any one who wishes to use it should do so with his eyes open, knowing what substance he is using and how much (which he does not in Anasarcin), knowing also that it has the same indications and limitations as digitalis. He should not be misled by such statements as the following

"Does what dropsy medicaments have hitherto failed to accomplish"

"Superior to digitalis, scrophanthus scoparius, squills, acetate of potash and the hydragogue cathartics all put together"

"The only known relief" (how modest!) "and permanent cure of dropsies"

"Unrivalled heart tonic" "The most powerful agent known"

Any one wishing to use squill should take the trouble to acquaint himself with the results obtained by competent and independent observers, and not rely on it in eclampsia, septicaemia, "rices of civilization," all forms of neurasthenia, as "an active eliminator of uric acid in rheumatism," in hepatic cirrhosis, dyspepsia, asthma, obesity, cystitis (!), lumbago, exophthalmic goiter, etc.

He should also learn the contraindications to the use of squill, deducible from the fact that it causes vasoconstriction and raises the blood pressure (prohibiting its use in Bright's disease and arteriosclerosis), and that it produces marked gastric irritation, consequently nausea and depression, that it is a very toxic agent, and that the dangers of cumulative action must be borne in mind. In respect to these the advertisements of the Anasarcin people are little short of criminal, for these state

"Safe in administration" "Non toxic as ordinarily administered" "Will nauseate some persons," but "the reaction from the temporary depression is prompt." "In Bright's disease, both the interstitial and parenchymatous forms of nephritis, acute or chronic no remedy to equal it in efficacy" "Without increasing the debility of the patient or interfering

with nutrition by producing loss of appetite" "Thus treatment is to be continued without cessation until all symptoms of dropsy have disappeared"

Physicians who are inclined to disregard this warning, and who follow the advice of the Anasarcin people, should remember that their patients—or their friends—will put the blame for the results, which are bound to follow sooner or later, on the prescribers, and not on the deceptive advertisements of the Anasarcin Chemical Company

There is another little matter which throws an illuminating side light on the Anasarcin Company. They take every occasion to say that Anasarcin is "not offered to the laity," "never sold to the laity," etc., but witness the following, which was found in the *Retail Druggist* of May, 1906, p. 170. The italics are ours

CURE FOR DROPSY

As every druggist knows dropsy has been one of the incurable diseases when caused either from heart liver or kidney trouble. A pharmacist in Winchester Tenn. has worked out a remedy called Anasarcin which he is exploiting to the physicians and his remedy is showing itself as possessing great merit. Several hopeless cases have been treated as a last resort by Anasarcin and in a very short time the patient has shown marked improvement and has effected permanent cures

The result of the cases as handled by the physician with the aid of Anasarcin has been so easily and quickly cured that physicians of Tennessee and the southern states are high in their praises of the remedy. The company which now manufactures and sells it is known as the Anasarcin Chemical Co. of Winchester Tenn. Any druggist who knows of a case of dropsy would be conferring a favor on the patient and mankind in general by telling the party or his physician of the southern pharmacist and we have no doubt but what a prompt relief and permanent cure would be effected [Probably means effected—Ed.]

(To be continued)

Correspondence

The German Surgical Congress

BERLIN, April 6, 1907

To the Editor—The thirty-sixth annual meeting of the German Surgical Society has just come to an end. It has occurred to me that it might be of interest to some of your readers to learn something of its management. In many respects it is a decided improvement on the conduct of similar meetings with us, and we would do well to imitate them. Of the scientific proceedings I shall say nothing, as these you will get from others

The society has over 1,600 members and 76 new ones were added this year. It is, therefore, the largest, and I think it is fair to say also the most important surgical society in the world. Over 800 were in attendance. The meetings are always held in Easter week in the Langenbeckhaus, in Berlin. As the hall seats only 500 to 600, cards of admission have to be shown. Even the aisles were well filled. Strangers are admitted to a rather narrow gallery on three sides of the hall.

The arrangement of the hall is excellent. It is nearly square the seats rising abruptly as in an amphitheater, so that all can see and hear well. It is lighted wholly by a large sky light, and by electricity at night. The president, flanked by the other officers, sits on a long, raised platform and back of him is a higher platform or "tribune" to which each speaker ascends. Back of the speaker is a blackboard with a wainscoted wall on each side on which charts, pictures, etc., were fastened by the thumbtacks used by artists. Above this wainscoting and on the side walls were hung a number of portraits. In the middle was Langenbeck and, as if to show that surgery includes pathology and the surgical specialties, von Craefe's portrait hung on his right and Virchow's on his left. Among the others were Billroth, Czerny, v. Eschmarch, Thiersch and other Germans, while Lister, Paget, Spencer Wells and Ollier represented the international character of our science. von Bergmann's portrait was appropriately draped in crepe. The sorrow for his so recent death was universally expressed and during the president's address, when he had spoken of their loss, the entire audience rose for a moment to express their homage and respect. Few men have wielded a wider influence especially by his charming personality and his handsome presence. It would be hard to find four finer looking men than Langenbeck, Bergmann, Eschmarch and Czerny

The congress lasts four days instead of three, as is usual with us, and the hall was as full on the last day as on the first. It is a series of serious meetings, with surgery as the important business to be transacted. They meet from 9 to 1 and 2 to 4, beginning and ending promptly. No time is lost at lunch, as this is served in the lobby at a most reasonable price. No social functions interfere with the scientific business of the day. Only in the evening are there any dinners. Attention to the business of the meeting is essential, for though the rule of the society allows only 70 papers, there were 100 on the program this year, and in addition to these there were a few discussions. No wonder that so poorly a volume of Transactions is issued every year. There were some unavoidable absentees, and so probably only 80 to 85 papers were actually presented. Moreover, only a few of these were read, and those not usually *in extenso*. Fifteen minutes is the time allowed for papers and five for demonstrations and discussions, though the rule was not very strictly adhered to. If a speaker was dull and uninteresting (of which there were only four or five, I think) the audience did not hesitate to give him notice to stop by slight but very perceptible shuffling and stamping of feet. There was no applause, not even at the end of the president's address. The only expressions of approval were half-murmured "bravos" on a few occasions.

Not only was the blackboard freely used, but there were generally drawings, models, specimens, photographs, skin graphs and many patients shown, which added greatly to the interest and the comprehension of the audience. While not a few of the papers were by younger men, yet the German deference to age, distinction and official position was much in evidence. The "Ausschluss" members make up a sort of large Executive Committee, who transact most of the business. They are generally among the older and more distinguished men. They are admitted by a separate door and occupy the front seats, and are prominent in the proceedings.

Even the treasurer's report was brief and a still shorter summary was placed on the blackboard for every one to see.

Readers of papers generally read only abstracts, but publish the papers in full. Most of them instead of reading gave *extempore* the substance of their communications. The speaking even in debate, was excellent, rarely with hesitation or halting and the German was fluent and well pronounced. The few who read from manuscript generally made the mistake so common with us, of reading very closely. A reader should know his manuscript so well that for at least two thirds or even four fifths of the time he can look into the eyes of his audience. Only so can he hold their strict attention. A close and especially a drowsing reader puts them to sleep.

There were few discussions but these were admirable. Those who took part were well chosen and had evidently prepared themselves. They added something to the subject discussed. *Per contra* there was very little spontaneous debate that is debate properly so called, little of quick expert fencing, few sparks from the clashing of firm but differing views, little of that ready repartee which is often seen with us. Most of the papers were not even submitted for discussion. When one was held it was generally on a group of allied papers. Indeed, there was no time for more.

Professor Riedel of Jena was an admirable presiding officer, with a clear voice, clean-cut enunciation and a fund of humor which lightened most agreeably the sometimes over-serious proceedings. Never was an audience more responsive. They 'caught on' instantly.

Professor Riedel is succeeded by v. Eiselsberg of Vienna, a most excellent choice.

In one respect we certainly should institute a reform—our long drawn-out dinners. Rarely do we get away till 12 or 1 o'clock and I am sure that no one who was present at the British Medical Association dinner at Montreal in 1897 will forget his weary wending to his hotel toward 3 a. m. Here the single official social function was the dinner on Thursday evening. The invitation named 5.30 p. m. as the

hour. We sat down at 6. The dinner consisted of only six courses, besides cheese, fruit and coffee. The speeches began after the first course, and while they were being made the waiters waited. Professor Riedel, of course gave as the first toast "The Kaiser." He was followed by König, Küster, Czerny, v. Eiselsberg and Rovsing of Copenhagen. The president introduced no one. Each rose, apparently spontaneously called attention by linking his glass, spoke for three to five minutes, and after the three "Hochs," the next course was served. By 8.30 we broke up into little groups, and many went home, and by 9 o'clock—when we would be only at the beginning—nearly everybody had gone. One private dinner was at 5.30, the others at 6.30 p. m. If I can persuade American medical men to adopt such a sensible procedure I shall not have written in vain. I can not see that there is any real obstacle to prevent such a genuine and welcome reform.

Most of the leading men were here. In addition to those I have mentioned there were Rehn, Lauenstein, Helferich, Gluck, Garre, Lenhart, Körte, Bardenheuer, Kimmell, Rydiger, Kausch, Krause, Mr. Arthur E. Barker of London, and many others. Unfortunately, Trendelenburg, Kocher, Bier and some others were unable to come.

The relic of mediæval barbarism, the deformities resulting from scars received in student duels, I thought less in evidence than in former visits to Germany. Such scars only make handsome men ugly and ugly men *noch hässlicher*. In a country so highly developed intellectually, it is a marvel that such a custom can persist at all. If my observation is correct, it would seem that it is dying out—a consummation devoutly to be wished. Whether I am right in this or not, I am surely right when I say that nowhere will an American surgeon receive a heartier welcome than from his German colleagues, and nowhere will he be apt to learn more.

W. W. KILL

P. S.—Just as I finished this letter Dr. James H. Honan called to invite me to a meeting of the "Anglo-American Medical Association," which was founded by him and of which he is still president. Its headquarters are in Rothacker's Buchhandlung, 105 B. Friedrichstrasse. Every Saturday night they dine at 7.30 in Room No. 1 Heidelberg Restaurant in the same building as the Central Hotel, opposite the Friedrichstrasse station and only five minutes' walk from the Langenbeckhaus. At 9.30 they have a lecture or informal talk by a German professor or doцент. This evening's lecture was by Schleich—him of the 'fluid'—and was excellent. The association numbers usually from sixty to eighty. The entrance fee is only \$1. They are doing an admirable work in helping American students in selecting their courses of study and giving information and help in every possible way. A similar Anglo-American club exists in Vienna with its headquarters at the Cifc Poliklinik, opposite the Allgemeines Krankenhaus.

Not only should every American student in these cities join these clubs but the older men should visit them and encourage our younger hard-working colleagues. If I may judge by my experience to night such visits are most highly appreciated.

Miscellany

The 'Lancet' on the Work of the Council on Pharmacy and Chemistry

Under the caption "The American Medical Association's Proprietary Remedies," the *Lancet* (April 29) writes as follows:

The Council on Pharmacy and Chemistry of the American Medical Association is making excellent progress in the campaign for the reform of the trade in drugs. For over two years a body of experts has been collecting information concerning the proprietary remedies of the United States and has been publishing with a certain regularity

The Association has just issued two publications which indicate the results of this investigation up to the present time. One of these booklets contains monographs on a number of unofficial and proprietary drugs tentatively approved by the Council on Pharmacy and Chemistry. This is to form the basis of a volume to be called "New and Non Official Remedies." The other booklet contains a number of reports by committees and analysts on proprietary medicines to which recognition in that volume is to be refused. No article advertised to the public is accepted for inclusion in "New and Non Official Remedies," nor is a recommendation for the treatment of any particular disease permitted on the label or on an accompanying circular. A false statement by the manufacturer as to the origin, source, or therapeutic value of this drug prevents recognition, and the Council insists that in the case of every compound the names and proportions of all active medicinal ingredients and of alcohol, together with the identity of any preservative used, shall be honestly disclosed. In the case of chemical substances, structural formulas are also required. The manufacturer's statements are checked when necessary by analysis in the laboratory. If the trade name of an article be insufficiently descriptive the Council reserves the right to include in "New and Non Official Remedies" a descriptive title as well as the trade name. The Council is careful to state that even when all these conditions have been duly complied with, acceptance does not connote a recommendation but merely implies that so far as is known the fixed ethical standard has been reached. The monographs in the booklet thus tentatively approved follow to some extent the model set by pharmacopœias. As nearly all the remedies included are the subject of proprietary rights, the trade name—whether this be registered trade mark or not—forms the title of each monograph, a fact which will greatly benefit firms owning any kind of proprietary interest in the names of remedies. Following this are synonyms, then the description of the remedy, its method of preparation, distinctive characters and tests, actions and uses, and dosage. Finally, the name of the manufacturer and the nature of his rights, whether arising through a patent or a trade mark, are given.

The second of the two booklets issued by the American Medical Association contains, as has been stated, reports on certain proprietary articles which do not reach the ethical standard laid down by the Council on Pharmacy and Chemistry. Sometimes the report consists merely of quotations from advertising literature, the language of which is itself sufficient to explain to the medical profession why the articles referred to have not been acceptable. In one or two cases letters from irate manufacturers objecting to give away their trade secrets are printed. Analytical reports show that proprietary brands of "metabolized cod liver oil" and "cod liver oil cordial" contain no cod liver oil at all. A preparation freely advertised both in the United States and in Great Britain as a "laxative salt of lithium" was found to consist almost wholly of sodium citrate and sodium sulphate. A number of proprietary powders and tablets were found to contain so large a proportion of acetanilid as to disentitle them to the recognition of the Association. A proprietary "coca wine" emerges unsuccessfully from the ordeal of analysis accompanied by a scrutiny of the advertisements of the wine. The committee believes that this wine is intended primarily to be a beverage, not a medicine. For one reason or another a considerable number of substances have been weighed in the balance and found wanting.

This authoritative separation of proprietary remedies into two distinct classes is a notable step in advance of previous attempts to deal with a growing difficulty and a grave evil. Many proprietary compounds and so called synthetic drugs are articles which ought not to be prescribed by medical practitioners in any circumstances. The difficulty has been that the medical profession has had no satisfactory means of distinguishing between the worthless and the useful. For it is undoubtedly true that some remedies which are the subject of proprietary rights are valuable and almost necessary additions to the therapeutic agents at the service of physicians. However much we may object to the principle of private monopolies in things which are a public necessity, it would be

too much to expect that a manufacturer who spends large sums of money on chemical and clinical research should dedicate to his trade competitors the advantages of the genuine discoveries of his employes. The American Medical Association has recognized this at the onset and has begun its work with conspicuous wisdom. For the future it contemplates the formation of a corps of medical consultants connected with large hospitals and also the establishment of a chemical and pharmaceutical laboratory in the Association's premises. Many more substances still have to be investigated, but from the work which has already been accomplished it may fairly be anticipated that the publication of "New and Non Official Remedies" when completed will serve a most useful purpose. There will then no longer be any excuse for the prescribing by medical practitioners of discreditable proprietary medicines, or for the acceptance by newspaper proprietors of fraudulent advertisements in respect of such nostrums. If medical men, pharmaceutical chemists and druggists are willing to take active steps to educate public opinion in the matter of quack medicines, educative material in plenty will be supplied by the American Medical Association, whose action will only need their energetic support in order to confer a conspicuous benefit on the body politic.

"What Fools These Doctors Be"

In the April number of the *Memphis Medical Monthly* appears an article with the above title by Dr Buford of Memphis. The arguments he uses to establish the truth of his statement are many. The paper is too long to quote in full, but some of Dr Buford's remarks are entitled to reproduction. He says "Physicians are not diplomats, but they do more for the advancement and welfare of mankind than do all the statesmen combined. They are poor, yet they do more charity than all the philanthropists put together. They are not over religious, but they practice more Christianity than do the clergy. They are not over virtuous, but they are the custodians, often, of a woman's purity, and too often of her good name. They are the public servants, yet they carry more secrets in their innermost souls than ever were confessed to priests. The average doctor's influence is great in his community, yet he is the tool of every demagogue and politician."

As to the manner in which the profession has been duped by the proprietary medicine manufacturer, Dr Buford, as might be expected, has very positive ideas. He says "We are especially used by proprietary medicine men, and, like the patient ass, we meekly submit to their burdens and only occasionally kick when we are prodded too deep. They approach us with samples and bait us until we begin to prescribe their products, without knowing what they contain, and most of us don't care so long as they are palatable, give results and have names which are easy to write."

Dr Buford carefully sets forth the way in which physicians are victimized by professional dead beats. He says "If you fail to meet your obligation at the bank promptly, this becomes known to every banker in the city, and when you again stand in need of money, the banker will tell you that he is sorry, but he has no funds to loan. But when the patient who has worked Dr S as long as he can, rings up Dr B and tells him to come right up to his house, Dr B goes in all haste to see him and gives him his best efforts and is fed on promises as long as they will last, after which the patient sends for Dr J. There are enough doctors in Memphis for him to have a new one every week or so for several years."

His conclusions are that physicians themselves are responsible for most of the charges in the indictment and that, if it is true that doctors are fools, they have no one to blame but themselves.

WHAT IS CRYOSCOPY?

WASHINGTON D C April 20 1907

To the Editor—In THE JOURNAL April 20 1907 on page 1349 second column and second line of last paragraph appears the word cryoscopy I am unable to find this word in either of my three dictionaries and would appreciate an explanation of its meaning of the word C C A

ANSWER—The word cryoscopy comes from the Greek *krýos* cold frost and *skopos* to see As used in physics it means the determination of the freezing point of a liquid In medicine it has reference to the process of comparing the freezing point of blood urine liquor amnii effusions etc. with that of distilled water Cryoscopy of the blood is of value in determining the functional activity of the kidneys Cryoscopy of the urine is of comparatively little value In fact Sahli believes that the freezing point of a urine free from sugar and protein may be estimated by multiplying the last two figures of the specific gravity carried to the third decimal place by 0.75 C Its value is based on the principle that the freezing point of any liquid depends on the kind and amount of solids held in solution by that liquid The lower the freezing point the greater the concentration Definitions of this term are found in Gould's Appleton's and Dorland's medical dictionaries and in the Standard dictionary and it has been frequently mentioned in THE JOURNAL during the last four or five years as will be seen by referring to the index of the various volumes Determination of the lowering of the freezing point of the urine in case of suspected kidney disease is now among the routine functional tests in some clinics and hospitals abroad Some consider it important in determining the functional capacity of the other kidney in contemplating nephrectomy The technique of cryoscopy was mentioned in THE JOURNAL June 4 1904 page 1518 and was described again May 26 1906 page 1634 with accumulating evidence as to its diagnostic value

TREATMENT OF EAPACHE

CHICAGO April 25 1907

To the Editor—If Dr Young (THE JOURNAL April 20 page 1668) will use the following prescription for his patients with ear ache he will certainly relieve the sufferers

R Phenol (acid) carbolic	m x	65
Chloral hydrate		
Camphore oil	gr x	65
Oleic acid q s ad	5 iv	15

M Heat the mixture and fill the ear with it and then cover the ear with a hot damp cloth I have used this prescription for seven years with perfectly satisfactory results J P Pickard

The Public Service

Army Changes

Memorandum of Changes of Stations and Duties of Medical Officers U S Army, week ending April 27, 1907

Lyster W J L asst surgeon will proceed from Fort McIntosh Texas to Fort Sam Houston Texas for temporary duty Rhoads T L asst surgeon granted leave of absence for one month effective about May 1 1907

Sweeney V B asst surgeon granted 80 days leave of absence effective about May 20, 1907

Heard G P asst surgeon, will proceed from Fort Wingate N M to Fort Huachuca Arizona for duty as member of board of officers to examine candidates for admission to U S Military Academy

O'Connor R P asst surgeon will proceed from Fort Leavenworth Kan, April 29, 1907, to Fort Crook Neb for temporary duty

Byrne C B asst surgeon general relieved from duty in the Philippines Division to take effect at such time as will enable him to comply with this order and will proceed on transport to sail from Manila about July 15 1907 to San Francisco Cal and on arrival report by telegraph to the Adjutant General of the Army for further orders

The following named medical officers are relieved from duty at the posts designated after their respective names to take effect at such time as will enable them to comply with this order and will proceed at the proper time to San Francisco Cal and take transport to sail from that place about June 5, 1907 for the Philippine Islands and on arrival at Manila will report in person to the Commanding General Philippines Division for assignment to duty

Wyeth M C surgeon, Fort Wadsworth N Y

Snyder H D surgeon Fort Sam Houston Texas

Smith A M surgeon Fort Douglas Utah

Fuller L A asst surgeon U S Military Prison Fort Leavenworth Kan

Skinner G A asst surgeon Fort William Henry Harrison Montana

Robbins C P asst surgeon Fort Ethan Allen Vermont

Rhoads T L asst surgeon Fort Crook Neb

Wilson J S asst surgeon Fort Ogleshorpe Ca to accompany the 26th Infantry from Fort Sam Houston Texas

Edger D T Jr asst surgeon Fort Reno Okla to accompany the 26th Infantry from Fort Sam Houston Texas

Lyster W J L asst surgeon Fort McIntosh Texas to accompany the 26th Infantry from Fort Sam Houston Texas

Reno W W asst surgeon Fort Riley Kan to accompany the 10th Cavalry from Fort Robinson Neb

Ives F J surgeon relieved from duty in the Philippines Division and will proceed from Manila about June 15 1907 to San Francisco Cal thence to the Presidio of San Francisco Cal for duty at that station

Kendall W P surgeon relieved from duty in the Philippines Division and will proceed from Manila about June 15 1907 to San Francisco Cal thence to Fort Sam Houston, Texas for duty at that station

Winter T A surgeon relieved from duty in the Philippines Division and will proceed from Manila about June 15 to San Francisco Cal thence to Fort Myer Va for duty at that station

The following named medical officers are relieved from duty in the Philippines Division to take effect at such time as will enable them to comply with this order and will proceed on the transport to sail from Manila on or about July 15 1907 to San Francisco thence to the posts designated after their respective names and report to the commanding officers thereof for duty

Shillock Paul surgeon Fort Robinson Neb

Fisher H C surgeon Fort D A Russell Wyo

Kulp I S surgeon Fort Meade S D

Stark A N surgeon relieved from duty in the Philippines Division to take effect June 15 1907 and on expiration of his leave of absence will proceed to Vancouver Barracks, Wash for duty at that station

Yost J D Field, P C Banta W P asst surgeons relieved from duty in the Philippines Division and will proceed on the transport to sail from Manila about July 15 1907 to San Francisco and on arrival report by telegraph to the Adjutant General of the Army for orders

Barney C N asst surgeon will proceed to Denver for special surgical treatment and on the conclusion thereof will return to his proper station

Davidson W T asst surgeon is detailed as a member of the Army retiring board appointed to meet at Denver by Par 12 S O 122, Mar 22 1906 War Department vice Captain George P Heard asst surgeon hereby relieved

Moss L M deputy surgeon general relieved from duty as chief surgeon Department of Texas and will proceed to San Francisco Cal and take transport to sail from that place July 5 1907 for the Philippine Islands and on arrival at Manila will report to the Commanding General Philippines Division for assignment to duty

Moseley F B asst surgeon general will report in person to Brigadier General William P Hall adjutant general 1st Resident of the Army Retiring Board appointed by Par 8 S O 299 Oct 9 1906 War Department at such time as he may designate for examination by the board and on completion of his examination will return to the place of receipt by him of this order

Newgarden G J surgeon retired from active service on account of disability incident thereto on April 24 1907

Shaw H A surgeon left Fort Slocum N Y with recruits en route to San Francisco Cal

Long C J dental surgeon left Fort William Henry Harrison Mont for duty at Fort Missoula Mont

McAllister John A dental surgeon left Fort Sheridan Ill for duty at Fort Wayne Mich

Halliday F A cont surgeon granted leave of absence for one month

Whitney Walter cont surgeon relieved from duty at Fort Irrelle Me and ordered to Fort McPherson Ga. for duty
O Day S E cont surgeon ordered from New York City to Fort Totten N Y for duty
Wren R J cont surgeon relieved from duty at Fort Totten N Y and ordered to Fort Slocum N Y for duty

Navy Changes

Changes in the Medical Corps U S Navy for the week ending April 27 1907

F A Asserson passed asst surgeon detached from the *Columbia* when placed out of commission and ordered to the *Kansas*

T J Kennedy passed asst surgeon detached from the *Hancock* and ordered to attend course instruction at the Naval Medical School Washington D C

R C Ramsdell asst surgeon detached from the *Maine* and ordered to *Connecticut*

H A May asst surgeon ordered to the Navy Yard Norfolk Va
M C Baker acting asst surgeon detached from the Navy Yard Norfolk Va and ordered to duty at the Naval Hospital at that place

J G Field, surgeon detached from duty with Marine Recruiting party at Dallas Tex. and ordered to duty with the Marine Recruiting party at Houston Tex May 12

I L Jones asst surgeon orders of March 20 modified ordered to the *Albatross*

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended April 24 1907

Carrington P M. surgeon detailed to represent the service at the meetings of the National Association for the Study and Prevention of Tuberculosis and the twenty fourth annual meeting of the American Climatological Association to be held in Washington D C May 6-9 1907

Lavinder C H passed asst surgeon granted leave of absence for one month from April 24 1907

Hobdy W C passed asst surgeon directed to proceed to San Francisco Cal for special temporary duty on completion of which to rejoin station

Bogges J S, passed asst surgeon directed to proceed from St. John N B to Quebec Canada for duty in connection with the examination of alien immigrants

Bailey C W, acting asst surgeon granted leave of one day April 23 1907

Bullard J T acting asst surgeon granted leave of absence for nine days from March 28 1907 account sickness

Foster S B acting asst surgeon granted six days leave of absence from April 19 1907

Kentley H W acting asst surgeon granted leave of absence for three days from April 16 1907 under Paragraph 210 of the Regulations

Onuf B acting asst surgeon granted leave of absence for two days from April 10 1907 account sickness

Schwartz Louis acting asst surgeon granted leave of absence for four days from April 7 1907 account sickness

Schug F J acting asst surgeon granted leave of absence for fifteen days from May 3 1907

BOARD CONVENED

Board of medical officers convened to meet at Galveston Texas April 22 1907 for the physical examination of an officer of the revenue cutter service Detail for the board Passed Asst Surgeon C M Corput chairman Acting Asst Surgeon William H Cammon recorder

ROBERT E. BRATTON, M.D., Willard, Tenn., to Miss Annie D. Wakefield of near Echo, Macon County, Tenn., April 17

Deaths

William Baldwin Fletcher, M.D. College of Physicians and Surgeons in the City of New York, 1860, of Indianapolis, a member of the American Medical Association, formerly president of the Indianapolis Medical Society, a member of the Mississippi Valley Medical Association, who served as a scout in the early part of the Civil War, and was captured and imprisoned and later was a member of the medical corps of the Army, a member of the Indiana State Senate in 1882 and 1883, from 1883 to 1888 superintendent of the Indiana Hospital for the Insane, who established in 1888 a private sanitarium at Indianapolis for the treatment and care of the insane, known as Neuronhurst, of which he was superintendent until his death, professor and later professor emeritus of nervous and mental diseases in the Medical College of Indiana, the school of medicine of Purdue University, and eminent as an alienist and medicolegal expert, died April 25 at Orlando, Fla., from the effects of a cerebral hemorrhage, aged 69

Mads Christian Christensen, M.D. University of Nebraska College of Medicine, Lincoln and Omaha, 1892, a member of the Council Bluffs (Iowa) Medical Society and Medical Society of the Missouri Valley, alderman of Council Bluffs from 1900 to 1902 and one of the most esteemed Scandinavian practitioners of Council Bluffs, died at his home in that city, April 16, from nephritis, after an illness of two weeks, aged 55

John W. Talbott, M.D. University of Pennsylvania Department of Medicine, Philadelphia, 1861, a surgeon in the Confederate service during the Civil War, a pioneer settler of Texarkana, Texas, and a member of the Miller County Medical Society, died at the Pine Street Sanitarium, Texarkana, from shock, two hours after an operation for cancer of the tongue, February 2, aged 67

Richard F. Michel, M.D. Medical College of the State of South Carolina, Charleston, 1847, a member of the Medical Association of the State of Alabama and Montgomery County Medical Society, surgeon in the Confederate service during the Civil War and widely known throughout the South as a physician and scientist, died at his home in Montgomery, April 19, aged 80

Herbert Smith Olney, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1901, formerly pathologist in the hospital of the Colorado Fuel and Iron Co., Pueblo, and later a practitioner of Detroit, died at the home of his father in Fresno, Cal., April 15, from tuberculosis after an illness of nearly two years, aged 30

Christopher B. Currier, M.D. University of Pennsylvania, Department of Medicine, Philadelphia, 1860, one of the founders and first dean of the Homeopathic Medical College of San Francisco, and president of the State Homeopathic Society, died in the Homeopathic Hospital, San Francisco, April 16, after a long illness, aged 78

Alfred J. Yost, M.D. University of Pennsylvania, Department of Medicine, Philadelphia, 1893, a member of the Medical Society of the State of Pennsylvania and Lehigh County Medical Society, mayor of Allentown, coroner of Lehigh County in 1895 and 1898, died at his home in Allentown April 16, from tuberculosis, aged 36

William Wilson, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1884, a member of the American Medical Association, a well known practitioner and clergyman of Coldwater, Mich., died in Harper Hospital, Detroit, from abscess of the lung, April 14, after a prolonged illness, aged 84

Francis Edmonds Corbin, M.D. Detroit Medical College, 1870, a member of the American Medical Association, until 1896 a practitioner of northern Michigan, and since that time a resident of Los Angeles, Cal., died at his home in that city, April 15, from uremia, after an illness of two days, aged 50

Junius F. Smith, M.D. Long Island College Hospital, Brooklyn, 1890, a member of the Connecticut State and Fairfield County medical societies, representative from Brookfield in the General Assembly, died at his home in Brookfield, April 22, from pneumonia, after an illness of two weeks, aged 42

Charles C. Blanchard, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1883, physician at the Delavan (Wis.) State School for the Deaf, a veteran of the Civil War, and formerly alderman and health commissioner of Delavan, died at his home in that city, April 19, aged 63

William Troy, M.D. McGill University, Medical Faculty, Montreal, 1891, some time president of the Ottawa (Ont.) Medical Association, and one of the staff of the Water Street Hospital in that city, died at his home in Ottawa, April 13, after an illness of a year and a half, aged 45

James Hogan, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1842, a practitioner of Henry County, Mo., for nearly 30 years, and later on of Fort Scott, Kan., and Springfield, Mo., died at the home of his nephew in Knobnoster, Mo., April 12, aged 91

G. Ernest Roy, M.D. Medical Department, Victoria College, Toronto, 1861, surgeon major of the Sixty-fifth Regiment, government inspector of anatomy, who served during the rebellion in Cuba, died at his home in Hochelaga, Montreal, from diabetes, April 14, aged 74

Samuel Jefferson Montgomery, M.D. Louisville (Ky.) Medical College, a member of the Arkansas State and Conway County medical societies, died at his home in Morrilton, Ark., February 2, from cirrhosis of the liver, after an illness of three years, aged 57

Henry Wells Spillman, M.D. New England Botanic Medical College, Worcester, Mass., 1848, who retired from practice 45 years ago, died at his home in Edgerton, Wis., April 1, one week after a fall in which he sustained a fracture of the head of the femur, aged 87

Joseph B. E. Gates, M.D. University of Tennessee, Medical Department, Nashville, 1876, a member of the Kentucky State and Fulton County medical societies, died at his home in Fulton, Ky., from abscess of the liver, March 15, after an illness of six weeks, aged 62

Edwin Gaylord, M.D. Rush Medical College, Chicago, 1866, Medical Department University of Nashville (Tenn.) 1869, a veteran of the Civil War, and for many years a practitioner of Magnolia, Ill., died at his home in Pontiac, Ill., April 10, from pneumonia, aged 73

Addison W. Guernsey, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1854, for more than half a century a practitioner of Almond, Wis., died at his home in that village, March 3, after a long period of invalidism, aged 78

Charles A. Fortin, M.D. University of Bishop College, Faculty of Medicine, Montreal, 1897, of Lewiston, Maine, a member of the Maine Medical Association and Androscoggin County Medical Society, died in Las Palmas, Canary Islands, March 22, aged 34

William M. Kern, M.D. University of Pennsylvania, Department of Medicine, Philadelphia, 1847, surgeon in the Federal service during the Civil War, who retired from practice 15 years ago, died at his home in Germantown, Philadelphia, April 17, aged 86

Robert Wilkie Martin, M.D. Homeopathic Medical College of Pennsylvania, Philadelphia, 1865, a veteran of the Civil War for many years a practitioner of Philadelphia, died at his home in that city, April 11, after an illness of three years, aged 65

Cecil Metcalf Ross, M.D. Cornell University Medical College, New York City, 1902, formerly interne at the Smith Infirmary, Staten Island and the Sailors' Snug Harbor Hospital, died in La Paz, Bolivia, South America, March 24, from pneumonia, aged 30

Jonathan F. Leaming, M.D. Jefferson Medical College, Philadelphia 1846, an aged practitioner of Cape May Court House, N. J., died in that place, April 25, from the effects of burns received during a fire at his home, two days before, aged 85

Morris P. Roe, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1873, a member of the Medical Society of Guthrie, Okla., died at his home in Falls, Okla., April 7, from cerebral hemorrhage, after an illness of two hours, aged 58.

Ezra Weis, M.D. University of Maryland School of Medicine, Baltimore, 1851, surgeon of the Ashland (Ky.) General Hospital during the Civil War, a practitioner of Peoria, Ill., for 20 years, died at his home in that city, April 12, aged 87.

James W. Gray, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1873, an old practitioner of Calhoun, Mo., died at St. Joseph's Hospital, Kansas City, Mo., April 10, two days after an operation on the intestines, aged 62.

Charles W. Austell, M.D. Atlanta (Ga.) Medical College, 1893, a member of the South Carolina Medical Association and Union County Medical Society, died at his home in Union, S. C., April 13, after an illness of one month, aged 45.

Edwin D. Q. Lowther, M.D. Kentucky School of Medicine, Louisville, 1883, a member of the Clarke County (Ark.) Medical Society, died recently at his home in Hollywood, from pneumonia, after an illness of 13 days, aged 40.

Cary Randolph Bankhead, M.D. St. Louis Medical College, 1850, a member of the Pike County (Mo.) Medical Society, died recently at his home in Paynesville, Mo., from catarrh of the bowel, after an illness of one week, aged 71.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and methods of treatment for the diseases seen especially in every day practice. Contributions will be welcomed from our readers.]

Antiseptic Powder

The *Druggists Circular*, April, 1907, publishes the following formula for antiseptic powder, furnished by F. E. Dudson, Charleston, S. C.

R Sodii salicylatis
Acidi borici, aa ʒss 15
Sodii bicarbonatis ʒiii 90
M Sig Two teaspoonfuls in a pint of warm water Use as a douche

Erythematous Eczema

Shoemaker, in the *Nashville Journal of Med and Surg*, gives the following treatment of this condition.

The patient is kept at rest in bed, and is allowed only milk diet. Calomel, gr. ii (0.13), is given in doses of a tenth of a grain (0.06) every half hour, this is followed by administration of magnesium sulphate, ʒiiss (45). In addition, the patient is given internally vinum antimoni, min. x (0.6) every three hours in water.

Externally, to allay the itching, the following combination is applied with a sponge.

R Creosoti m x 6
Magnesi carbonatis ʒss 2
Zinci carbonatis precip ʒv 24
Glycerini fʒi 4
Liquoris calcis fʒiv 15
Aque hamamelidis q s ad fʒi 30
M Ft lotio

Tinea Sycosis

In the treatment of this condition, the same author, in the *Hot Springs Med Jour*, states that in order to bring about a cure daily local applications of some anti-parasitic remedy are all that is required. Constitutional remedies are not absolutely necessary. A 10 per cent. ointment of the oleate of mercury is applied twice daily. This at once lessens the infiltration and induration of the parts and destroys the parasite. To prevent extension of the infection a 10 per cent. solution of thymol in olive oil should be rubbed in over the entire bearded surface.

The prognosis in this condition is always favorable, but the time required to effect a cure varies considerably. In some cases the simplest measures suffice, while in others months may elapse before the disease is eradicated. Occasionally the disease may terminate in spontaneous recovery, but as a general rule if untreated it assumes a chronic form and persists for years.

Coryza

This complaint occurs most frequently in the spring and autumn months, though to some extent it is always with us and is one of the most common conditions which we have to treat. The disease is probably caused by a micro-organism though in some cases it seems to be caused by irritation as from the fumes of certain drugs or by dust.

E. S. McKee, in the *Therapeutic Gazette*, advises spraying the nose once daily with an alkaline and antiseptic solution, then with a 1 per cent. solution of cocaine with 0.40 per cent. of boric acid. Five minutes later he uses a 2 per cent. spray of antipyrin, and five minutes later insufflates with calomel, lastly, 1 per cent. of menthol in liquid petrolatum is sprayed into the nose.

Among a host of sprays for coryza he recommends the following:

R Menthol gr viii 5
Camphora gr v 3
Petrolati liq fʒi 30
M Sig Use as a spray
R Adrenalin chlorid ʒi 4
Cocain hydrochlorid gr i 60
Salt solution (8 per cent) fʒiii 60
M Sig Use as a spray two or three times daily

The patient should lie down for a few minutes after using this spray and should remain indoors for some time afterward. [The cocaine spray should only be used or dispensed by the physician. The patient should not be given a prescription.—Ed.]

R Sodii salicylatis
Sodii chloridi
Sodii bicarbonatis, aa, q s ʒiii 100
M Sig A teaspoonful in one half pint of water and use as a spray

R Hydrogeni peroxidi fʒi 30
Hydrargyri chloridi corrosivi gr i 60
Zinci sulphocarbolutis gr x 133
Aque dest fʒv 148

M Sig Use as a spray after cleansing. As a stimulant to the mucous membranes the following may be used.

R Thymol gr 1/3 62
Olei carophylli m iii 19
Petrolati liq fʒi 30

M Sig To be sprayed in the nares two or three times a day

R Phenol (acidi carbolici)
Menthol
Olei gaultheriae, aa gr i 66
Petrolati liq fʒi 30

M Sig Use as a spray three or four times a day when an antiseptic is needed.

As a sedative the following may be used.

R Olei carophylli m iiii 50
Terebenti m vii 70
Petrolati liq fʒi 30

M Sig Use as a spray

R Olei cassiae m ii 13
Menthol m iiii 19
Petrolati liq fʒi 30

M Sig Use as a spray

Snuffing of liquids of an alkaline and antiseptic character is often beneficial. McKee recommends the following simple alkaline and antiseptic wash which can be made up at home. Salt, one half teaspoonful, carbonate of soda, one teaspoonful, phenol (carboic acid), 10 drops, water, one pint. This is best used lukewarm, the patient stooping over, snuffing it through the nose and spitting it out of the mouth. If snuffed through the nose in the erect posture or with the head thrown backward there is danger of the solution passing through the Eustachian tubes into the ear and causing trouble. These alkaline solutions, if used regularly in flushing out the nares, are very beneficial in preventing coryza.

Another consists of equal parts of salt, borax and bicarbonate of soda, one teaspoonful to a pint of water, use lukewarm.

Hare's "Practical Therapeutics" states that camphor may be inhaled or taken internally in the early stages of cold in the head, with great relief, and that it exercises a decided influence in aborting an attack. The following formula may be employed.

R Camphora
Quinine sulphatis, aa gr ii 12
Fluidextracti belladonnae m iiii 60

Ft. tabellæ No. x Sig One tablet every hour for four or five doses.

After the attack is well developed this is useless, but used early it will decrease the frontal headache, the sneezing and running at the nose.

This author asserts that much benefit follows the use of sodium bicarbonate in 30 grain (2.0) doses every two hours for three doses. He also states that a hot footbath with mustard in it and the taking of a hot drink such as lemonade, with or without whiskey, on going to bed, are useful. Often 20 or 30 minims (1.3-2.0) of sweet spirits of nitre added to this drink will increase its diuretic effect. In other cases particularly in strong healthy men, from 5 to 10 grains of Dover's powder at bedtime will be found more efficacious.

Medicolegal

Statements Made to Physician by Injured Person.

The Supreme Court of Alabama says, on the appeal of *Gregory vs State*, a homicide case, that as to statements made to a physician by the party who is the subject of the injury, the rule of exclusion extends as to declarations of its cause, or the way in which it occurred, these being regarded as mere narratives of past events, which must be proved by other and independent evidence. But, from the necessity of the case, he may testify to the party's statements as to his symptoms, the locality and character of the pain, and give an explanation of his bodily condition, made while suffering, and for the purpose of enabling the physician to form an opinion of the nature and extent of the injury. There was no error in permitting the physician to state what the deceased said during the examination as to his stomach and legs, namely, that he had no feeling in feet or legs, and had burning in the stomach.

Evidence and Damages in Case of Femoral Hernia.

The Supreme Court of Washington says that the personal injury case of *Hodd vs City of Tacoma* was brought to recover damages for personal injuries alleged to have been sustained by falling on a defective sidewalk. Almost immediately after the accident the plaintiff was removed to a hospital and subjected to an exploratory surgical operation for inguinal hernia. A few weeks later it was discovered that she was suffering from a femoral hernia, requiring a second operation, which was then performed. It was not seriously disputed that the first operation was performed immediately after the accident, that the plaintiff was confined in the hospital for six weeks thereafter, and that as soon as she attempted to stand on her feet it became apparent that a second operation for femoral hernia was necessary. The plaintiff claimed perfect health prior to the accident. The court holds that there was no error, under all the circumstances of the case, in permitting one of the attending surgeons, over objection, to testify that, in his opinion, the hernia last mentioned might have resulted from the plaintiff's fall on the sidewalk. It also holds that a judgment for \$5,000 damages was not excessive, or to be disturbed, inasmuch as the plaintiff's physicians gave testimony tending to show that some of her injuries were permanent, the testimony of her physicians standing without substantial dispute, while the defendant did not ask for the appointment of any commission of physicians to examine the plaintiff and report on her condition.

Photographs of Portions of Human Body as Evidence

The Supreme Judicial Court of Massachusetts says that in the personal injury case of *McKarran vs Boston & Northern Street Railway Company*, during the testimony of the physician who attended the plaintiff, in describing the nature and extent of the enlargement of a portion of the vertebra of her spine, photographs of this portion of the back were introduced and used by him as illustrations. While the photographer was not called, the witness, whose medical qualifications were not questioned, testified that the photographs were taken in his presence, and under his direction, and on admission they must be considered as forming a part of his evidence. *Alberti vs New York, Lake Erie & Western R. R. Co.*, 118 N. Y. 77, 88.

The competency of such evidence if relevant, whether consisting of a model, diagram map, plan, picture or photograph, is established and is admitted for the purpose of giving to the jury a representation of the object or subject concerning which the inquiry is made and to enable them better to understand the issues on trial. *Blair vs Pelham*, 118 Mass. 420, 421. Before admission however there must be a verification of the accuracy of the representation and this is a preliminary inquiry to be made by the presiding judge whose decision is final. *Clapp vs Norton*, 106 Mass. 33 and other cases.

The defendant placed great reliance on *Cunningham vs Fair Haven & Westville R. R. Co.*, 72 Conn. 244 as an authority establishing a different rule but after discussing the weight to be given such a finding the court expressly says

"We are not now called on to determine the legal correctness of a finding of this kind, or whether it can be reviewed. The question presented by the record is whether it was error to admit this photograph without any evidence of its accuracy."

Again, the defendant contended that a higher degree of verification was necessary and should have been required than when the representation describes inanimate objects, as the accuracy of the reproduction of the animate human form varies according to the position and adjustment of the camera, the skill of the artist and condition of the atmosphere. It is undoubtedly true that the photographer may produce a picture which is misleading when compared with the subject represented, but so can the civil or mechanical engineer by his plan drawing or model made by hand, and while such misrepresentation may result from lack of professional skill or proper adjustment of the photographic apparatus, it also may be the deliberate product of the most skillful exercise of the art.

This ground of possible deception when the human form is either wholly or partially portrayed was not, however, recognized as a distinction in *DeForge vs New York New Haven & Hartford R. R. Co.*, 178 Mass. 59, where a radiograph of a fractured human foot, if properly taken, was held to be admissible when verified in the usual manner, while in *Com vs Campbell*, 155 Mass. 537 and in *Com vs Morgan*, 109 Mass. 375, on the question of identity, a photograph showing the defendant's personal appearance was held to have been properly admitted. In each of these cases physical characteristics were depicted, and if admissible to show the appearance of one part of the human body there would seem to be no sufficient reason why a photograph of other parts, when relevant, and properly verified, should be excluded.

The testimony of the photographer was not required if the judge was satisfied by other evidence, as he apparently was that they were substantially accurate representations of the plaintiff's person. *Com vs Morgan*, above cited. *Van Houten vs Morse*, 162 Mass. 414. *Archer vs N. Y. N. H. & H. R. R. Co.*, 106 N. Y. 589, *McGar vs Borough of Bristol*, 71 Conn. 652.

- 6 The Stomach Tube in Diagnosis. N. B. Foster. New York.
- 7 Unsuccessful Operation for Intestinal Obstruction on a Child of Fifty-five Hours. H. Crutcher. Mexico, Mo.

1 Refraction Changes Dependent on Glycosuria.—Could report a case of refractive changes due to glycosuria observed by him and also the histories of 22 cases observed by others that have been published. He says that eye strain may have aided in producing the functional dietetic and nutritional disease called glycosuria, that the majority of cases are in presbyopes that eye strain and glycosuria form a vicious circle, that warnings given by refraction changes should lead to immediate treatment of early and curable cases of glycosuria to prevent the later organic changes in the ocular structures.

2 Unusual Results of Intrathoracic Compression. Parin gar reports three cases of collateral venous circulations of unusual extent following thrombosis and compression of the superior vena cava and left innominate vein and an uncommon physical sign of bronchial compression. The sign consisted of a hyper resonant or tympanitic note over the affected bronchus.

3 Treatment of Tuberculosis in Arizona.—Presented a plea for more care in selecting suitable localities for the treatment of tuberculosis in Arizona.

Arizona and urges that only such patients be sent as have means to secure proper food and comforts. He gives a concise statement of the advantages and possibilities of the different health resorts of the state.

- 15 Tuberculous Peritonitis, with Report of Cases E Novak Baltimore.

8 Appendicitis—Wyeth reports seven cases to emphasize the great danger in delaying surgical intervention in typical cases of appendicitis, and in all cases of recurring, though mild, attacks.

10 Treatment of Typhoid Spine—Gibney insists on the use of the Paquehn cautery as a regular line of treatment so long as tenderness and pain on movement exist. He says that even after all tenderness subsides it is a good plan to employ the cautery occasionally, once a week, or once in two weeks. The administration of hypnotics should be left to the individual practitioner.

14 Modified Buttermilk in Infant Feeding—Judson and Clock fed 12 infants suffering from malnutrition and enteritis on modified buttermilk, with excellent results. The longest period of continuous feeding on buttermilk was six weeks.

In preparing the buttermilk for these cases two deviations were made from the usual method. The casein was diluted considerably to make the proportion present from 15 to 2 per cent, and the sugar added only in sufficient amounts to bring the proportion present in the mixture up to 5 per cent. Moreover, the mixture was not brought to the boiling point, but heated only to from 140 to 155 F for ten minutes, so that the lactic acid bacteria were not destroyed. Robinson's barley flour was added instead of wheat flour, one half ounce to each pint and a half, and cane sugar solution (6 and 9 per cent strength) was used to dilute the casein.

The method of preparation of the weaker mixture was as follows. Ingredients used were one pint of buttermilk, eight ounces of a 6 or 9 per cent solution of cane sugar, one half ounce of Robinson's barley flour. 1. Make a paste of the flour and a small quantity of the sugar solution. 2. Add buttermilk and the remainder of the sugar solution to this paste and mix thoroughly. 3. Heat the mixture to 155 F for 10 to 15 minutes, stirring constantly. 4. Remove from stove, cool, and place on ice.

In feeding the infants on buttermilk the principle followed was to begin with a moderately strong mixture, which they called "two thirds" mixture, containing from 1 to 15 per cent fat, from 4 to 5 per cent sugar, and from 15 to 175 per cent proteid. After tolerance for this mixture had been established as evidenced by normal temperature and good condition of the stools, the fat percentage was increased. If the infant's digestion still remained good, the formula was increased to "three fourths" mixture with a simultaneous increase in the fat percentage. The three fourths mixture contained from 15 to 25 per cent fat, 5 per cent sugar, and from 175 to 2 per cent proteid.

- 19 *Periductal Myxoma of the Breast W P Graves Boston
- 20 *Intrapleural Injections of Formalin in Pleurisy with Effusion L D Chapin Springfield Mass

19 Myxoma of Breast—In the case reported by Graves the tumor was so large and cumbersome that the patient when sitting down was obliged to rest it on a table or on the arm of a chair. The patient was only 38 years old and the tumor which weighed 16 1/2 pounds, was first noticed three years pre-

viously. It was entirely discrete and was removed easily. During the last two or three months the tumor grew very rapidly, due to a sarcomatous metaplasia.

20 Pleurisy with Effusion.—Chapin reports a case of pleurisy with effusion, in which he injected intrapleurally a 2 per cent formalin solution in glycerin. Only one injection was made, but it resulted in a cure. Other treatment, which had been employed previously, did not prevent a reaccumulation of the fluid so that repeated tapings were necessary.

- 25 The Medical Expert and His Trials E S McKee Cincinnati

23 Varicose Veins of Tongue—Johnston reports the case of a woman, 64 years old, who had suffered much from throat trouble, cough and shortness of breath. On examination he found on both borders of the tongue, beginning at the anterior pillars, and extending forward to within half an inch of the tips bluish, tortuous masses, round, and measuring about 4 mm in diameter. The ramne veins on the under surface of the tongue were unusually large and tortuous. The condition had caused no inconvenience and no cause for its presence was discoverable. There were no signs of congestion in the throat. Johnston is inclined to believe that the enlarged veins were of congenital origin.

30 Biology of Diplococcus Intracellularis—During the 1904-5 epidemic of cerebrospinal meningitis in New York, Flexner, as a member of a commission appointed by the health department of New York for the investigation of the disease, made an exhaustive study of the pathogenic properties of *Diplococcus intracellularis*. The brief vitality of this organism on artificial media is not due to exhaustion of the medium or to accumulation of products except, perhaps, when in large quantities. When suspended in salt solution the cocci rapidly die. Not only is the solution fatal, but they soon lose their staining properties and disintegrate. He finds, too, that cold is injurious; a temperature just above zero being quickly fatal. In the cold, disintegration, however, is less rapid. Hence it is concluded that disintegration is the result of enzyme action. The diplococcus lives much longer in medium to which some calcium has been added or in Ringer's solution. This shows that the brief viability in salt solution is not due to hypertonicity of the medium, to starvation alone, or to a natural brief period of vitality, but that sodium chlorid is distinctly poisonous to the diplococcus, and this poisonous action is at least partly offset by other salts. The enzyme in question is intracellular and is liberated by the death of the cell. It is not destroyed at 60 C at which temperature the organism is killed, but at 65 C, and at higher temperature its activity is much reduced. It acts alike in sodium chlorid and in Ringer's solution, but potassium cyanid inhibits its power of causing disintegration of the cell, if the potassium cyanid is subsequently removed autolysis proceeds again. The enzyme is not specific but causes disintegration of many other varieties of bacteria both Gram and non Gram staining, the latter more easily than the

former. The author concludes that the autolytic and proteolytic ferments are independent since the diplococcus produces no proteolytic ferment, and the autolytic ferment in certain organisms as pyocyanus, which produces marked proteolysis, is very slightly autolytic.

Strains of the diplococcus of meningitis vary much in their pathogenic properties, the freshly isolated ones being on the whole much more virulent than those under artificial cultivation for a time. Some strains remain virulent for a few days, others for months. When the virulence is once lost it can not be restored by animal passage. When comparatively small quantities are injected into guinea pigs intraperitoneally, death usually results in less than 24 hours. The autolysates (autolyzed fluids) also are toxic, even if centrifuged, and if filtered through porcelain. The toxicity is not reduced at 65 C, and hence the toxic body and the enzyme are independent since the latter is appreciably affected at this temperature. The death of the animals is produced by the toxin liberated by the disintegration of the bacterial cell and not by extracellular poison.

31 Experimental Cerebrospinal Meningitis.—In the lower monkeys Flexner was able to produce an acute inflammatory condition of the meninges which resembles very closely the lesions produced by the *Diplococcus intracellularis* in man. The organisms obtained from typical cases of epidemic cerebrospinal meningitis were introduced directly into the spinal canal of monkeys by means of lumbar puncture. In the course of a few hours the animals became ill with certain characteristic symptoms and in a number of animals death took place in from one to three days. The lesions found at autopsy very closely simulate those occurring in man. In both are found encephalitis, acute endarteritis, inflammation of the dorsal ganglia, internal hydrocephalus, fibrinous and other thrombi, relatively small amount of fibrin in the exudates, phagocytosis of diplococci. The inflammation extends in monkeys into the membranes covering the olfactory lobes and into the ethmoid plate and nasal mucosa. The latter was often found inflamed, and smears from its surface showed cocci having many of the characteristics of the *Diplococcus intracellularis*. In none of the cases was it possible to cultivate the meningococcus, but this was probably due to its brief viability in the nose of the monkey. This olfactory inflammation is important because it shows that the localization of the exudate at the base of the brain is not necessarily produced by the infection arising from the nasal mucosa as has been assumed in human infections.

The degree of susceptibility of the monkey is very slight compared with that of man, because the amount of culture necessary to produce symptoms or to cause death is enormous compared with the probable amount necessary to cause the disease in man. The amount injected into the canal in these experiments varied from two loops of a fresh culture to several cultures. Flexner believes that the actual multiplication of the diplococci, except possibly in the abscesses, is very small, in some cases there is none at all. This is in marked contrast to what occurs in man. Injections of enormous quantities of the diplococcus intravenously or into other tissues of the body produce practically no symptoms except a slight local tenderness and swelling.

32 Serum Therapy for Experimental Diplococcus Infection.—Flexner concludes from experiments that while various agents as normal and immune sera and even bouillon may affect favorably the course of an experimental infection, immune serum possesses the highest protecting power. The outlook is not especially encouraging, however, since the infection in the animals used is so rapidly fatal. Two monkeys were immunized against the diplococcus by successive injections for a period of nine months. The animals were bled to death the sera collected and its immune properties tested by injection into the spinal canal of monkeys simultaneously with cultures of diplobacilli and also after a period of six hours. The results show that monkeys injected simultaneously with serum and culture in this manner may be prevented from developing severe symptoms by separate injections of the culture and six hours later of the serum the monkey already ill could be saved apparently from certain death.

The normal monkey serum also has some protective power when employed in certain cases. In other cases the mixture of serum and diplococci served to hasten the fatal outcome. No attempt is made to apply these results to human beings affected with meningitis. The results on the whole were not constant or striking enough to warrant great expectations. Possibly the more protracted course in man as compared with that in the inoculated animals may be a favorable condition, and by treatment with appropriate antisera, at the proper time, more encouraging results might be obtained. The protective power of normal serum might also be taken advantage of, in cases of human infection, by intraspinal inoculation.

36 Heterotransplantation of Blood Vessels.—Carrel's experiments show that blood vessels transplanted from dog to cat act as arteries for 77 days at least, and that having spent several days in cold storage does not interfere with their ordinary functions. The animals operated on must, however, be kept under observation for several months, or, indeed, for several years, before any conclusion can be drawn concerning the practicability of this method of preservation and heterotransplantation of blood vessels.

39 Pyosalpinx.—Double salpingectomy was done by McGirk in 36 cases and single salpingectomy in 32 cases. Appendectomy was done at the time of operation in 17 cases.

41 Autotoxemia.—Warbrick reports seven cases of autotoxemia to illustrate his contention that the condition is one which may be mistaken for indigestion dyspepsia anemia malnutrition, etc.

42—See abstract in THE JOURNAL Oct 20, 1906, page 1122

43 Cardiac Disease.—Behan disclaims against pronouncing a case one of heart disease without attempting to make a more specific diagnosis. He reviews briefly the pathognomonic signs which are an aid in diagnosis.

44 Vincent's Angina.—Blackwood reports nine cases of Vincent's angina occurring in children ranging in age from 2 to 10 years. Of these nine cases ten were of the superficial or mild diphtheroid type, and two were in healthy children smears from whose throats showed the presence of *Bacillus fusiformis* in one instance, associated with the spirillum. The seat of the attack was the lips, tongue gums cheeks, tonsils or pharynx, and in none was there marked destruction of tissue. There was no glandular enlargement in any case.

45 Electricity in Rheumatism.—Rainear reports three cases of rheumatism in which he employed the continuous current successfully.

47 Urinary Nitrogen in Toxemia of Pregnancy.—According to Ewing and Wolf the study of urinary nitrogen furnishes a new and fundamental

tion of toxemia of pregnancy, which must be tested carefully, not with the idea of displacing other criteria, but with a view of supplementing them with information of a more precise character. The results of their observations lead them to believe that the urinary nitrogen may have the following practical applications in pregnancy. It may determine the existence and gravity of a toxic condition. In urgent cases it may be relied on with some caution to determine the safest treatment. It frequently establishes the trifling importance of symptoms referable to transitory gastric disorders. It may indicate an abnormal state of metabolism when other symptoms are absent, and thus form the basis of treatment designed to avoid some of the serious complications of pregnancy. It is of great value in determining the true condition of the patient in the pre eclamptic state, and in distinguishing between simple chronic nephritis and impending eclampsia. It is an excellent guide in determining the progress of convalescence. It is not to be relied on exclusively, however, and more than any other set of the phenomena of the disease, but only in connection with all the data in the case.

48 **Gonorrhea in Women**—Hunner discusses the lower genital tract infections, the urinary tract infections, the upper genital tract infections and peritoneal infection.

49 **Teratoma of Ovary**—Frank's patient, aged 35 years, mother of one child, gave a good family history and in her personal history there was no evidence of illness, tumors or multiple pregnancies. The patient had always experienced what she termed a weak feeling in the right side which manifested itself in weight, discomfort, and a dragging sensation, after even moderate exertion, such as walking. In September, 1898, she struck the right side of her abdomen against the edge of a table and soon after symptoms suggestive of appendicitis manifested themselves. The acute symptoms gradually subsided, but there appeared a gradual loss of strength, an increase of constipation and a slight rise of the evening temperature. Finally, a diagnosis was made of tumor, probably malignant, and operation was advised.

On opening the peritoneal cavity the greatly distended intestines crowded through the wound. Immediately behind the bowel an immense yellowish tumor presented, consisting of nodular, very friable masses, and large festoons of fluctuating, thin walled cysts of various sizes grouped in grape like clusters. The mass was everywhere adherent. On the peritoneum were lumps and nodules not connected with the main mass. The most accessible parts of the growths were severed between ligatures, great difficulty being experienced in removing a sufficient amount to permit of closing the abdomen. The patient's condition remained the same as before operation. She became progressively worse and died three months after ward. There was no autopsy. Microscopic examination of the tumor showed a teratoma in which all three fetal layers were well represented. There were present skin, with its appendages, nervous tissue, cysts lined with unclassifiable epithelium, bone, cartilage, connective tissue, unstriped muscle, analogues of the embryonal intestine and acinous glands. The active stage of the disease extended over about seven months, death resulting from general inanition.

50 **Removal of Ovaries**—Bovée summarizes his paper as follows: 1. The existence of an ovarian secretion has not been proved and therefore should not act as a bar to oophorectomy. 2. In all cases of removal of the uterus or its body for disease in women of more than 40 years the ovaries would best be removed. 3. As 5 per cent of malignancy exists in the cases of uterine fibroids brought to operation, and in 30 per cent marked complications of the appendages are present, leaving the ovaries when the uterus or its body is removed for such condition is hazardous to the future well being of the patient. 4. In malignant disease of the uterus in which radical surgery is indicated removal of both ovaries is imperative. 5. The indications for removal of the ovaries when partial or complete hysterectomy is done are increasing instead of diminishing. 6. When ovarian growths of a bilateral nature complicate the hysterectomy both ovaries should be removed, though one seems normal.

52 **Etiology of Endometritis**—Ewald presents a general review of this subject, but presents nothing new.

- 58 *Is the State Medical Examining Board a Success? J. R. Stevenson, Haddonfield.

55 **Plea for Use of Standard Pharmaceuticals**—Sherk discusses this subject from the same standpoint as that taken by other writers with whom he agrees as to the cause of the indiscriminate use of non official remedies and how to encourage the use of standard preparations.

58 **Is State Medical Examining Board a Success?**—Stevenson says that experience tends to impress on us the view that no board composed of physicians only can prevent the people from looking on them with a suspicion of interestedness. The paper rather conveys the impression that state boards and medical examiners are not as great a success as most people are inclined to believe.

California State Journal of Medicine, San Francisco March

- 68 *Treatment of Pyelitis and Urethritis by Urethral Catheterization and Lavage. G. L. Laton, San Francisco.

61 **Instrumental Diagnosis**—Cooper cites an instance which emphasizes the necessity of injecting a little sterile water into a catheter or any other tube which is perforated before the tube is withdrawn so as to force away from the eyelet the mucous membrane, which otherwise might be torn off and brought away with the tube. When the proctoscope is used air instead of water may be injected.

64 **Laboratory Methods in Diagnosis of Typhoid**—Allen discusses briefly the various methods that are of value in diagnosing suspected cases of typhoid, such as blood cultures, serum diagnosis, and the leucocyte count.

66 **Focal Operations in Hip Joint Tuberculosis**—Sherman says that the possibility of health from an operation directed against the diseased focus in the hip should be considered and discussed very carefully, and that this must always be done with one thought clearly kept in mind, that a tuberculous bone lesion is practically always more serious and more extensive than outside evidences lead one to believe. He has done the tunneling operation five times, but in only one case was it apparent that the operation could have been a success.

68 **Catheterization and Lavage in Pyelitis and Ureteritis**—Eaton reports the history, urinary analysis and treatment in 23 cases of pyelitis and ureteritis, 8 bilateral and 15 unilateral. The treatment consisted of passing the urethral catheter every third or fourth day and injecting into the pelvis of the kidney about 5 c.c. of a 2 per cent silver salt solution. Marked improvement resulted in each case. Eaton emphasizes the necessity for a careful examination of the urine previous to and during the treatment.

- 1 *Lord Lister and the Evolution of Wound Treatment During the Last Forty Years H C Cameron
2 *Dr H Jackson's Views of Functions of the Cerebellum V Horsley
3 *Iodin Spirit Catgut J S Riddell

1 Evolution of Wound Treatment.—Among the points considered by Cameron in his discussion of the evolution of wound treatment are the following Acupressure, earliest form of antiseptic treatment, the buried ligature, the introduction of protective and shellac plasters, and of antiseptic gauze, the antiseptic spray, the employment of drainage tubes, mercurial gauze dressings, antiseptics by heat sterilization of the skin, hands and instruments, the treatment of compound fractures and of chronic abscesses associated with osseouseries

2. Functions of Cerebellum—Horsley's conclusion is that all research tends to confirm the view held by ancient and modern investigators that the cerebellar cortex is the first chief station of representation of the afferent basis of movements of all the skeletal muscles

3 Iodin Spirit Catgut.—As the result of two years of constant use of this catgut Riddell is convinced that it is sterile that it loses none of its tensile strength in preparation that

it can be stored indefinitely in the solution in which it is prepared without becoming brittle, that it is soft and nice to handle, that it is readily and simply prepared and without any undue expense, and that it is absorbed completely but only after it has served its purpose

6 Acute Abdominal Conflux.—The area of acute abdominal conflux is described by Childe as being an area bordered by two lines in which almost every acute abdominal crisis either must or does occur A perpendicular line is drawn from opposite the esophageal opening of the stomach, about one inch to the left of the sternum on the seventh costal cartilage, to Poupart's ligament A second line is drawn from the right anterior superior iliac spine, perpendicularly upward to the lower border of the thorax Between these two lines is the area of acute abdominal conflux The incision which will lay bare this area is a vertical one midway between the lines, just about the outer border of the right rectus This is the incision of incidence. It commences about the level of the umbilicus and continues downward Childe claims that this incision exposes to sight that part of the abdominal cavity which in a large proportion of cases must contain the offending organ, and which in another large proportion of cases does, as a matter of fact, do so When it fails to expose the offending organ the abdomen can be examined by touch just as well through the right semilunar as through the median incision

7 Amyl Nitrite in Hemoptysis—Grace Calvert claims that nitrite of amyl is the most valuable drug in practically all cases of hemoptysis It produces such an immediate fall in the general blood pressure, by dilatation of the vessels throughout the body, that the pressure at the bleeding point is lowered and there is time for clotting to take place, while the hemoptysis usually ceases almost instantly The inhalation of three minims usually checks the bleeding almost at once

58 Lateral Suture of Artery After Extirpation of Sac Aneurism.—Garré reports what he believes is the first case of extirpation of a true sacculated aneurism with lateral suture of the artery and recovery of the patient. The aneurism had developed from the vein, but the artery was adherent to the vein at this point with a communication between them. The aneurism was resected, the vein ligated above and below, and the opening into the artery closed with a longitudinal suture in the side of the artery. He adds that in case it is deemed unwise to apply the tourniquet, the flow of blood through the artery can be arrested by passing a loop of thread around the vessel, above and below, and occluding the lumen by kinking the artery by simple traction on the thread. This method is less dangerous than application of forceps or direct ligature which is liable to injure the intima.

60 Injuries of Liver.—Dencks reports seven cases of injury of the liver in which surgical treatment was successful in three. The injuries in the cases with a favorable outcome were: A bullet wound, a kick from a horse, and injury from being run over. The others were very serious contusions with other injuries. Rigidity extended over the entire abdomen in every case, and the pain on palpation was also diffuse, although more pronounced on the right side. Tamponing alone arrested the hemorrhage in the three favorable cases. The pulse gave no signs of the internal bleeding, being relatively good even in the most rapidly fatal cases. In one instance the gauze tampon answered a double purpose, draining a pus pocket that developed between the diaphragm and the liver. His experience confirms the value of tamponing as the best, safest, most rapid and effectual method of arresting hemorrhage in case of rupture of the liver, although a suture may be advisable for a smooth and conveniently located stab wound.

62 Operative Treatment of Multiple Tuberculous Strictures of the Intestine.—Ito and Asahara report five cases. One of the patients succumbed a few months later to acute phthisis. Three others were restored to comparative health. The symptoms are those of any gradually encroaching stricture in the intestines, but they were less pronounced when the stools were watery than with solid stools. Partial exclusion with lateral enteroanastomosis was done in three cases and the results were brilliant in every instance. In another case nothing was done beyond the mere laparotomy, as more than 29 cicatricial strictures of a moderate degree were scattered along the entire small intestine. This patient is still in the clinic and has had no colics since, but the pulmonary affection is continuing a progressive course. The patient treated by resection of 95 cm. of the small intestine succumbed to collapse. Lateral enteroanastomosis relieves the patient at once of all disturbances and by improving the general condition promotes the chances of spontaneous elimination of the remaining infectious germs. Cases are on record in which even a process in the lungs retrogressed afterward.

63 Permanent Cures After Cancer Operations.—Steiner reports from Dollinger's clinic at Budapest that of 175 cancer patients operated on 40 per cent are living at least three years after the operation, and 41.25 per cent of 80 after an interval of five years at least. These figures include 25 and 18 cases in which the cancer had recurred but had been promptly removed. The cancers are classified according to their location, and the experiences with each group are reviewed in detail.

64 Pathology and Treatment of Ileus.—Göbell publishes the report of 63 cases of ileus in which operative treatment was undertaken at Helferich's clinic at Kiel, 1899-1906. In only two instances was it possible to palpate a strangulated loop through the rectum or vagina. Distended loops felt in this way generally proved to be parts of the afferent intestine. In the 21 cases with strangulation the pain was localized in only

three, but shock was always present, and initial vomiting occurred in all but five cases. A free effusion was observed in 11 cases. In one the modification of the resonance on change of position led to the assumption of a tuberculous effusion, but puncture brought the contents of the small intestine instead of the expected effusion. He regards appendicostomy as extremely useful and indicated in case of ileus when there is cancerous stenosis of the colon, and in case of volvulus of the cecum and ascending colon if it can be reduced in time. At the same time the appendicostomy fastens the movable colon to the abdominal wall. It is useful also in case of volvulus of the sigmoid flexure when it has gradually developed and the intestine above is very full, also in ileus from paralysis in which the large intestine is extremely distended and can not be evacuated with high injections. The outcome was favorable in 48.3 per cent of the 31 cases in which the intestine was emptied, and in 47.2 per cent of the 21 cases in which this was not done. He adds that the main trouble is that patients do not reach the surgeon in time. Better results will be recorded when physicians learn to diagnose strangulation ileus in time, and when they learn that an expectant attitude in case of ileus from occlusion increases the danger from day to day, and that many human lives are sacrificed to the teachings of internal medicine.

68 Diagnosis of Acute Mediastinal Affections.—In the case described by Arx a brakeman was thrown under a car and was injured in the heart region by being pushed along by one of the wheels. The fourth left costal cartilage was fractured and the fourth intercostal branch of the internal mammary artery ruptured. The blood escaped into the anterior mediastinum and into the left pleural cavity, but the pericardium did not seem to be injured. Large moist râles and crepitation were audible under the lower part of the sternum, and here only, later subsiding at this point, giving place to dulness, and appearing at a higher point, near the manubrium. There was no emphysema and nothing to indicate injury of the air passages. Arx ascribes this finding to the gradual development of the hematoma in the anterior mediastinum. It pressed back the right half of the heart and thus brought it into a more vertical position, which caused the apex beat to be remarkably strong, coming concentrically direct from below instead of the usual tangential beat. A third unusual symptom was a whistling sound audible at a distance and synchronous with the heart systole. The chest wall vibrated to correspond with this sound, which was audible for about two hours and then vanished to recur again next day for an hour or so. The patient rapidly recovered under expectant treatment, but there is still, a year later, a tendency to cough on exertion, with brief pain in the heart region and along the left margin of the sternum when he coughs or sneezes or lies on his side. The whistling sound Arx explains as due to the concussion of the air in the trachea from the heart as a note is produced in an organ pipe.

80 **Specific Solubility in Forensic Blood Tests**—Dehne has been studying the phenomenon that specific turbidity and precipitates in a combination of serum and antiserum become rapidly dissolved when undiluted homologous serum is added in excess. Even with mere traces of blood, the appearance of this specific solubility, testing with serums of various organs, points unerringly to the kind of animal from which the blood originally came.

81 **The Blood in Asthma**—Salecker calls attention to the great fluctuations in the blood picture in cases of asthma. During or immediately after the attack there is pronounced hyperleucocytosis, generally chiefly in the polymorphonuclears, which may increase to 80 per cent of the total number of leucocytes or even more. The mononuclears, especially the eosinophiles, diminish materially in numbers, but conditions return to normal in the course of a few days. He remarks that we are accustomed to see such violent reactions on the part of the blood only in consequence of bacterial or chemical irritation. His communication is based on examination of 14 asthmatics, half of whom were examined during and immediately after an attack.

82 **Impure Heart Sounds in Children**—Neumann reports several typical cases in which the children were apparently healthy, with nothing to call attention to the heart except the discovery of a lack of purity in the heart sounds. He noticed this in his private practice in 71 children under 5 years, in 89 between 6 and 10, and in 20 older children. This change in the character of the heart sounds came on suddenly, and he is inclined to think that it is permanent. Preceding catarrhal affections of the upper air passages is almost invariably mentioned in the history, and he thinks that involvement of the heart in infections of the upper air passages, especially of the nose, is so common that the heart should be supervised in all such cases. Children with this anomaly in the heart sounds evidently have something more or less wrong with the heart. Although slight cyanosis and shortness of breath are sometimes observed, as a rule there are no signs indicating disturbance beyond the one mentioned, and the children take cold baths and exercise violently—against the physician's advice—with apparent immunity. It is evident, however, he thinks, that the heart is not intact, and that the life expectancy is more or less modified by it.

83 **Operative Treatment of Laryngeal Stenosis**—Wendel's patient fell on the edge of a chest and fractured the larynx with resulting cicatricial stenosis. The cicatricial tissue was excised by laryngotomy and the mucosa was mobilized and drawn up to cover the defect, which extended half way around the larynx. The outcome was excellent.

85 **Prophylaxis of Retention of Placenta**—Durlacher is inclined to attribute retention of the placenta to reflex action from manipulation of the uterus or abdominal wall. The best

means to prevent it, therefore, he says, is to abstain from touching the uterus or abdomen after the child has been delivered. Inspection and control of the pulse and the higher position of the uterus will reveal internal hemorrhage, generally in less than half an hour. When this is observed Credé's method of expression can be applied. He urges the adoption of this strictly expectant treatment on a wide scale in order to test its results. In his experience it permitted spontaneous detachment and expulsion of the placenta even in cases in which at previous childbirths there had always been more or less trouble from this cause, requiring manual measures and accompanied by much hemorrhage.

86 **Antitoxin Treatment of Tetanus**—Urban reports two cases of tetanus in which death soon followed injection of antitoxin. In a third case no benefit from the antitoxin was visible. As a last resort the compound fracture of the leg was rinsed with 1 per cent silver nitrate solution daily, commencing the tenth day of severe tetanus, the first symptoms were noticed the twentieth day after the accident. The patient rapidly recovered.

90 **Study of Pancreatic Juice and Determination of Trypsin**—Volhard introduces 200 cc of olive oil into the fasting stomach and in half an hour pumps it out again. The oil induces copious secretion of pancreatic juice, and more or less of it finds its way into the stomach. He describes a simple method with which he was able to determine the presence of active trypsin in the stomach contents in 80 per cent of 22 cases. This allows excellent oversight of the functional capacity of the pancreas. In one case the absolute absence of pancreatic juice in the stomach was explained by autopsy, which showed the pancreas completely transformed into connective tissue with the duct occluded by concretions. The symptoms during life had been those of severe diabetes without acidosis.

91 **Tests of Stomach Functioning**—Lewinski's experience does not indicate that Sahl's desmoid test has much value, as catgut does not behave in the stomach like the ordinary raw connective tissue. This explains the occasional contradictory findings. Schmidt's connective tissue test, however, has proved constantly reliable. This is the ingestion of a certain amount of finely chopped raw meat, slightly browned in the oven. Under normal conditions this is completely digested in the stomach; not a trace of the connective tissue appearing in the feces. If it passes through the stomach undigested, it is not attacked by the intestinal juices, and is found in the stool. This was the basis on which Sahl developed his test, but catgut acts differently in the stomach from raw meat fibers.

92 **Injurious Action of Ether and Chloroform on the Blood Vessels of Internal Organs**—Mulzer has experimented with 64 animals under general anesthesia and his findings sustain the assumption that ether and chloroform have a directly injurious action on the red corpuscles, dissolving them when long in contact. When the anesthesia had been kept up for more than half an hour the vessels in the lungs, liver and kidneys were obstructed with disintegrated red corpuscles and thrombosis was evident at certain points. These findings had no connection with the amount of the anesthetic administered nor the position of the animal. Injection of ether or chloroform directly into a vein produced the same results as prolonged general anesthesia.

93 **Suction Therapy for Affections of Ear and Upper Air Passages**—Vohsen has devised a simple means of influencing the nasal sinuses and evacuating morbid secretions. It is based on the Bier method of aspiration with a cupping apparatus but no apparatus is required. The benefits of the Bier aspiration treatment are the result of the alternation of compressed and rarefied air. The same results can be accomplished. Vohsen says in affections of the sinuses or middle ear by blowing into the nose, which is held closed, and thus compressing the air in the sinuses, then aspirating out their contents with the mouth and throat muscles, the glottis being closed. The negative pressure that can be thus obtained is much higher than with any mechanical device to date. Hyperemia is induced in the parts, the sinus is emptied and the procedure can be repeated at will by the patient without harm. Pr 111

ing his throat as in the position of yawning and then aspirating out the air with the nose closed tight, he succeeded in drawing out part of an effusion in the middle ear. The only possible drawback to this technic, he adds, is the possibility of conduction of the pressure to the middle ear, but this can be avoided with a little practice. The method is not adapted to every case, of course, but when indicated will be found a great help. Muck gives an illustration of a glass tube whose end fits tight in the ear. The outer end carries a rubber bulb and its application for suction treatment of suppurative affections of the mucosa of the ear has given him uniformly and surprisingly good results. He has applied this treatment in 20 cases of obstinate chronic affections, applying the instrument for one or two minutes, with one minute intervals, and keeping this up for 15 minutes on alternate days. Healing was complete in every instance in from four to eight weeks. The benefit from the mechanical removal of the secretions is supplemented by the induced hyperemia.

94 Scopolamin-Morphin-Chloroform Anesthesia.—Kreuter writes from Graser's clinic at Erlangen to extol the advantages of this combined method of general anesthesia. He asserts that the lack of danger as the dosage is so small, the small amount of the chloroform or ether required, and the reduction of secretion under the influence of the scopolamin, are not the least of its advantages. He thinks that it may materially reduce the number of cases of postoperative pneumonia. The only drawbacks of the method that he has discovered are the uncertainty of the action of the scopolamin and the subjective sensation of dryness. He recommends the combination particularly for the long protracted operations, even for much debilitated patients, adding his testimony that "it is the most humane technic known to date."

95 Hydrogen Dioxid as Aid for Examination of Sputum.—Peters commends the addition of hydrogen dioxid to the sputum as a simple and most effectual means of breaking up tenacious masses and distributing the tubercle bacilli evenly through the specimen.

105 Amyloid Degeneration in Tuberculosis.—The researches reported by Sörgo, who is the medical chief of the great Alland sanatorium, demonstrate that amyloid degeneration in phthisis is always the result of mixed infection in case of a pulmonary process, or else is a sign of a tuberculous process in the intestines. The practical conclusion follows that in case mixed infection can be excluded by examination of the sputum, the discovery of amyloid degeneration points to an existing tuberculous process in the intestines. He gives the details of 49 patients examined from this point of view. He found that 35 of the patients had no signs of mixed infection in the sputum.

107 Hemolytic Blood Test in Diagnosis of Typhoid.—Hirschfeld has been studying the application of the deviation of complement as a test for the diagnosis of typhoid. The serum used was that taken for the agglutination test, and in the 15 cases under observation the results of the test were constantly positive and gave positive findings much earlier than the agglutination test. The findings proved strictly specific in his experience, and they ensured the diagnosis at an earlier date than was possible with the agglutination test. It requires an

expert, however, to make the test, as it would be too expensive, tedious and delicate for general practice, but the findings may prove of inestimable service in certain cases.

108 Laws of Elimination of Sugar in Diabetes.—Falta and Gigon state that their experience has confirmed that of others in respect to the difficulty diabetics encounter in the disposal of maltose. These patients are much less able to tolerate maltose than levulose or any other carbohydrate. The details of the metabolism in 8 cases are given in numerous tables, the metabolism studied from some new standpoints, emphasizing the "superposition curves," etc.

109 Trypsin in Treatment of Cancer.—In this communication from von Leyden's clinic, two laws regulating the growth of cancer are specially emphasized, namely, the fact that in its origin and growth carcinoma is a strictly local phenomenon, and that its most striking feature is its unlimited proliferating power. It is also pointed out that the tumor reacts with increased growth to all kinds of injuries, mechanical, thermal and chemical. For half a century medical science conducted its research on cancer almost exclusively along morphologic lines, but now the questions are: Is there a specific production of substances in cancer? and Is it possible to induce a specific destruction of these substances? Research has shown that there is probably a production of a specific albumin in malignant tumors, and that this albumin is promptly digested by the ferment trypsin. The experimental experiences with trypsin, so far reported, show that larger amounts of trypsin pass into the blood when it is given by the mouth than when it is injected subcutaneously. Injected directly into a carcinoma in man, the results proved disappointing. The resulting digestion of the cancer cells was always circumscribed and there was no question of a cure in any case. Given internally, even for long periods and in large amounts, no decisive influence could be demonstrated in case of inaccessible internal carcinoma. On the other hand, nearly every case of carcinoma of the stomach, not too far advanced and still free from metastases, exhibited an unmistakably favorable reaction to the trypsin. The verdict from this clinic is thus, that trypsin to date, while displaying a curative influence can not yet be heralded as a definite method of treatment. A new fact has been learned, however, possibly of far reaching importance, namely, that a tumor whose cells have been digested (dissolved) by the trypsin in some circumscribed area never reacts to this interference with increased growth, either locally or in general. This fact recalls the selection in respect to injections of radioactive substances. This exceptional absence of increased growth under the influence of the trypsin, von Leyden regards as significant, showing an actual specific destructive process even if it is only temporary.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review as dictated by their merits or in the interest of our readers.

TREATMENT OF SKIN CANCERS. By W. S. Gotthell, M.D. Adjunct Professor of Dermatology at the New York Postgraduate Medical School and Hospital. Third Edition. Revised and Enlarged. Cloth. Pp. 89. Price \$1.00. New York: Surgery Publishing Co. 1907.

COMMON BACTERIAL INFECTIONS OF THE DIGESTIVE TRACT and the Intoxications Arising From Them. By C. A. Herter, M.D. Professor of Pharmacology and Therapeutics in Columbia University. Cloth. Pp. 300. Price \$1.50 net. New York and London: The Macmillan Co. 1907.

ATLAS AND EPITOME OF DISEASES OF CHILDREN. By Dr. R. Hecker and Dr. J. Trumpp of the University of Munich. Authorized Translation from the German. Edited by Isaac A. Abt, M.D., Assistant Professor of Diseases of Children in Rush Medical College. With 48 Colored Plates and 147 Illustrations. Cloth. Pp. 453. Price \$5.00. Philadelphia and London: W. B. Saunders Co. 1907.

METABOLISM AND PRACTICAL MEDICINE. By Carl von Noorden. Professor of the First University Medical Clinic, Vienna. Anglo-American Issue Under the Editorship of I. Walker Hall, Professor of Pathology, University College, Bristol. Vol. I.—The Physiology of Metabolism by Adolf Magnus Levy. Berlin. Cloth. Pp. 450. Price \$4.00 net. Vol. II.—The Pathology of Metabolism by Carl von Noorden. Fr. Kraus. Ad. Schmidt. W. Weintraud. M. Matthes and H. Strauss. Cloth. Pp. 523. Price \$6.00 net. Chicago: W. T. Keener & Co. 1907.

SOME RECENT STUDIES ON HEREDITY *

EDMUND B. WILSON, PH.D., J.D.
Professor of Zoology, Columbia University
NEW YORK

For convenience of presentation we may speak of studies on heredity as having followed three principal lines of inquiry. One of these, often known as the statistical or biometric method, includes the statistical treatment by precise mathematical methods of large masses of data obtained by the observation of heredity and variation as they occur under natural conditions. With the results in this direction I shall in no way attempt to deal. I will only recall that the most widely known of them is embodied in Francis Galton's so-called law of ancestral inheritance, which attempts to state the quantitative effect on the offspring of their entire ancestry, including not only the two parents, but also all the more remote progenitors.

The second method is that of experiment, pre-eminently by observing the operation of heredity in hybrid forms produced by crossing two different species, races or breeds. The importance of such experiments does not lie in the fact that they deal with hybrids as such. It arises in the main from the practical consideration that when the parental forms differ visibly in one or more characters these can be more readily recognized, and hence more easily traced in the offspring than is the case with pure bred forms. Apart from this there is every reason to believe that the operation of heredity in hybrids does not differ in any essential way from that in pure bred forms, and hence the former may be taken to indicate what takes place in the latter where the parental forms do not differ in any conspicuous way. Probably the most important and certainly the best known, of the general results in this direction is the so-called law of Mendel (or better the Mendelian principle) to which we shall presently return. This principle is probably more complex and perhaps also of more limited application than was at first supposed, but no other phenomenon of heredity is of greater interest because it gives a new basis for a view of heredity as a whole.

The third method is an indirect one which includes the attempt to determine and study in detail the physical basis of heredity in the germ cell. It is especially this aspect of the subject that I shall endeavor in some degree to set forth, but this can not be done successfully without holding clearly in view some of the more striking facts of Mendelian inheritance even though their brief review must run the risk of going over ground already very familiar.

"UNIT CHARACTERS" AND HEREDITY

The most interesting of the specific results obtained by the experimental method relate to the so-called unit

characters and their behavior in heredity. The earlier observers thought of the hereditary organization on the whole in the way in which it is popularly regarded as a single and indivisible unit. The result of the union of two such units in reproduction was conceived as producing a new unit which is, on the whole, a blend of the original two somewhat as two liquids of different color may mix to form a third liquid of blended color. There are many hereditary qualities that do, in fact, conform to this—for instance, color and apparently also stature in man. The cross between the white and negro produces mulattoes, which, in turn, produce mulatto children the two parental color characters having permanently blended. But, as even the earlier observers perceived in some measure, there are other characters that show an entirely different behavior. Such characters, which exhibit the phenomena of Mendelian inheritance and are often spoken of as "unit characters," do not ordinarily mix or blend, but behave almost as if they were separate material entities which may be put together and taken apart again like the cards of a pack or the separate pieces of a mosaic work. A typical example is given by the cross between a common gray mouse and a white or albino mouse of the same extraction. The hybrid thus produced does not show a mixture or blend of gray and white, as might be expected, but *appears* pure gray. But the gray hybrid does not really lack the white character. This character is only concealed or "dominated" by the gray, for it may be recovered or "extracted" in the next generation. If such gray hybrids be bred together their progeny always include in the long run both white and gray forms and the "extracted" whites thus obtained are not only pure white in appearance, but when paired together produce only white offspring for an indefinite number of generations.

Gray and white may, therefore, be put together in a hybrid and afterward taken apart again without visible modification of either color, except that when the two are associated in the hybrid gray always conceals or dominates white. What is far more remarkable is the fact that gray and white mice issue from the gray hybrids in definite proportions—there being in the long run three grays to one white. This ratio does not often appear in a single litter of mice or in a few litters. In a large number of litters taken collectively it is found to hold with remarkable accuracy—when several hundred such mice are bred even within a fraction of 1 per cent. Clearly, then, the combination and dissociation of the two characters follows some definite law or principle which suggests that observed in chemical combination, but is not directly to be compared with the latter since an element of chance is present and the result must be treated by the method of probability.

The behavior of the white and gray unit character in mice is but an example of a phenomenon of a definite occurrence in both plants and animals and of a class of

* Lecture delivered before the Harvey Society, Jan. 27, 1907.

shown by a great variety of characters. A few examples of such characters in animals are the length, mode of growth and color of the hair in rabbits and guinea-pigs, the colors and mode of growth of the plumage and the structure of the comb in fowls, the color patterns of snails and butterflies, and even such apparently obscure characters as the color of the silk in the cocoons of silkworms or the peculiar "waltzing" habit of the so called Japanese mice. Among plants examples are the shapes of leaves, seeds, pods or pollen grains, the color of the flowers, the structure of the seeds and color of the seed-coats, and the hairiness or smoothness of the leaf surface. All these characters (many others might be given) present cases in which, when two contrasting or opposite characters of the same type are crossed, one alone, known as the "dominant," is visible in the first hybrid, while the other is "recessive," and the offspring of the hybrids in the long run show the two characters in the ratio of three to one. Evidently, therefore, we are dealing with a phenomenon of such wide occurrence that it must represent some deeply lying principle of inheritance.

The results are even more remarkable when, instead of limiting the case to a single pair of characters, two or more pairs are taken together. It is then found, in typical cases, that each pair of characters follows the Mendelian rule quite independently of the characters with which it is associated. But when the combinations of the two (or more) pairs are considered together they are found to fall into definite series, which rapidly increase in complexity as the number of characters rises, but follow a simple and definite principle. At this point these more complex combinations need not be considered. The point on which I would fix attention is that the principle of combination is such that when the hereditary composition of the parents is known in respect to one, two or any number of pairs of characters, both the qualitative and the quantitative nature of their offspring may be predicted often with astonishing accuracy. It has thus, in fact, become possible to write down hereditary formulas for animals and plants that exhibit this form of heredity which will express both their ancestry and their hereditary capacity. These formulas bear a curious resemblance to those of organic chemistry in that they have enabled the experimenter to predict the formation of new combinations not previously known, and then to create them by a suitable synthesis. Further, just as the chemist can in some measure predict the properties of his new compounds, so the biologic experimenter can in a measure predict the hereditary behavior of the new combinations thus called into existence.

CUÉNOT'S EXPERIMENTS

I will again illustrate this by color inheritance in mice describing a case which the French observer Cuénot first worked out on paper and afterward put to the test of actual experiment. The colors of mice are typical Mendelian "unit characters," so related that when two colors are united in a hybrid yellow dominates gray or black, gray dominates black, while any of these colors dominates the corresponding albino, or white character. The nature of Cuénot's experiment is shown in Table 1. A first cross was made between two white mice, one an albino of gray extraction (AG), the other an albino of black extraction (AB). The result is a white mouse of combined gray and black extraction (AGAB). Parallel to this, a cross was made between a pure black mouse (CB) and a white mouse of yellow extraction (AY), the result of which is a yellow mouse that has both black and white in its ancestry (CBAY). From a knowledge

of the hereditary constitution of the two mice AGAB and CBAY Cuénot predicted that they would produce eight different kinds of offspring, of which in the long run four should be white, two yellow, one black and one gray. Crosses of this type were then repeatedly performed until 151 mice of the third generation had been obtained. The actual distribution of the colors is shown in one column (Table 1), the theoretic expectation in the other, and, although the correspondence is not mathematically exact, it is so close as to leave no doubt of the correctness of the reasoning on which the prediction was based. The experiment might have been indefinitely continued by crossing any two of the eight kinds of mice thus obtained, and in each case a close prediction could have been made of the result. This is by no means an isolated case, but only a single example of a type of experiment that has been repeatedly performed, both in animals and in plants, with quite as striking a correspondence between theoretic expectation and reality. In general, the larger the number of cases observed the closer does this correspondence become.

TAB. 1.—HEREDITY OF COLOR IN MICE (Cuénot)

Grand parents (1st generation)	A G (white) A B (white)		C B (black) A Y (yellow)			
Parents	A G A B (white)		C B A Y (yellow)			
(2d generation)					(Calculated)	(Observed)
Offspring (3d generation)	$\left\{ \begin{array}{l} 1 \\ 2 \\ 2 \\ 4 \\ 5 \\ 6 \\ 7 \\ 8 \end{array} \right.$	A G C B	{ (gray) (black)		19	16
		A B C B			19	20
		A G A Y	{ (white)			
		A B A Y				
		A G A B			76	81
		A B A B				
		C Y A G	{ (yellow)		38	34
		C Y A B			152	151

Mendel's law or principle gives an extremely simple and lucid explanation of the seeming necromancy that is practiced in such predictions. This principle is simply that when a given pair of opposing or alternative characters (i. e., such as behave toward each other as dominant and recessive) are put together in a hybrid they are, in some sense, disjoined or separated in the eggs or spermatozoa of the hybrid, and in such a manner that half the germ cells in each sex contain the dominant character and half the recessive. In other words, the germ cells of the hybrid are no longer hybrid, but are pure like the parental forms. If now it be assumed that fertilization is quite fortuitous—that is, that the spermatozoon that fertilizes any particular egg is as likely to bear one character as the other—the observed facts follow as a simple matter of probability, and the explanation of the simple ratio shown by a single pair of characters carries with it that of the more complex series shown by the combination of two or more pairs of characters. To illustrate again by the mice. The gray and white cross produces the hybrid GW, which appears gray because of the dominance of gray over white. The eggs and spermatozoa of the hybrids are, however, not GW, but either G or W in equal numbers. If now the spermatozoon fertilize the eggs at random the probability is that the following combinations will appear in equal numbers: GG, GW, WG and WW or GG + 2GW + WW as shown in Table 2. The first produces a pure gray mouse, the second and third, hybrid gray mice, and the fourth a pure white mouse, that is, three gray to one white. The correctness of this interpretation is proved by crossing the gray hybrids (GW) with the pure white forms (WW). Whether the gray female be paired with the white male or the reverse, the result should be to give gray hybrids (GW) and pure whites (WW) in equal numbers. For the germ cells of the gray hybrid are gray

and white in equal numbers, while those of the whites are white only. The chances, therefore, are equal in favor of W meeting W or G, as shown in Table 3. This expectation is closely met by the facts. It is simply by the application of this essential principle—disjunction of the members of each pair of characters and the resulting "purity" of the germ cells—to the combinations of two or more pairs of characters that the experimenter is enabled to make his apparently marvelous predictions regarding the quality and quantity of the offspring. As has just been shown, the combination of one pair of characters gives four combinations that form a series of three terms (since the second and third combinations are identical). If two pairs of characters (which may be called Aa and Bb, the capital letter denoting in each case the dominant character) be taken together, their combinations will appear in a series formed by the simple arithmetical combination of the two series formed by each pair alone. That is, if each term of the simple series $AA + 2Aa + aa$ be combined with each term of the series $BB + 2Bb + bb$ the result is sixteen combinations, which (owing to the identity of certain ones) fall into a series of nine terms of the form $ABAB + AbAb + aBaB + abab + 2ABAb + 2aBab + 2ABab + 2Abab + 4ABab$. Some of these combinations are not externally distinguishable by the eye but must be tested by the nature of their offspring. For example, ABAB is not visibly different from AbAb since both show only the dominant characters, A and B, but they differ in hereditary capacity, since one can transmit only the two dominants, while the other may transmit also the two recessives, a and b. This difference is readily tested by breeding experiments. Inspection of the nine-term series will show that out of the sixteen combinations nine show both the dominant characters, A and B, three, one dominant and one recessive, A and b, three, the other dominant and recessive, a and B, and one, both recessives, a and b. Experiment shows that the four characters actually appear in combinations that closely approximate to the series thus worked out as a purely arithmetical construction. With three pairs of characters the nine-term series expands to one of twenty-seven terms, with four pairs to eighty-one terms, and so on. It is not necessary to follow all this out in further detail. It is sufficient to say that, given an experimental acquaintance with the relations of dominance and recessiveness between the characters, the predictions of the experimenter become a simple matter of mathematical computation.

TABLE 2.

Egg	G	or	W
Spermatozoa	G	or	W
$GG + GW + WG + WW$			
or $GG + 2GW + WW$			
3G to 1W			

TABLE 3.

Egg	G	or	W
Spermatozoa	W	or	W
$WG + WW + WG + WW$			
or $2GW + 2WW$			
Fgg	W	or	W
Spermatozoa	W	or	G
$WW + WW + GW + GW$			
or $2WW + 2GW$			

Such is the Mendelian principle stated in its simplest form and as it was conceived by Mendel himself. It has now become evident that as applied to certain cases (among which is included color inheritance in mice as will appear beyond) Mendel's own statement was probably too simple and further that many exceptions and modifications occur. I will return to this further on but for a presentation of the cytologic aspects of the

problem it will be convenient to confine ourselves at the start to the simplest form of statement.

THE GERM CELL AND HEREDITY

We may now turn to investigations on the structure and behavior of the cell that have revealed a mechanism that may be adequate for the physical explanation of the main facts of Mendelian heredity. It has now become the prevailing view (though it is not universally admitted) that the primary factors of heredity—I do not say the only ones—are contained in the nuclei of the germ cells, and on this assumption we shall proceed without reviewing the great array of evidence on which it rests. In approaching this subject we may again recall the fact that the unit characters behave in Mendelian inheritance almost as if they were material bodies that may be put together, separated and recombined in definite proportions. This remarkable fact would be intelligible if the material bases of the characters in the germ cells were separate substances or bodies that underwent corresponding combinations, dissociations and recombinations. The cytologist has good reason, therefore, to seek in the egg, or spermatozoon, and particularly in the nuclei of these cells, for discrete bodies that may serve as such bases of the characters.

THE CHROMOSOMES AND "UNIT CHARACTERS"

Whether this search has been successful or not is still a matter of opinion, but it is not a matter of opinion, but of fact, that the nuclei of the germ cells do contain or give rise to bodies, the history of which in the life cycle of the organism shows the closest parallel to that of the unit characters—so close that we can, in fact, apply to these bodies the same formulas by which the characters are designated and reach the same result. These are the bodies known to every histologist as the chromosomes—rod-shaped or loop-shaped bodies that are visible in the nuclei of the egg and spermatozoon at the time of fertilization and at the time of cell division in every cell derived from the fertilized egg. The chromosomes are constant in number in each species. At the first division of the egg and at each subsequent division each of them divides into two, the daughter chromosomes thus formed separating and passing one into each of the daughter cells. The chromosomes are thus handed on by division from cell to cell throughout development, always retaining their specific character, and hence we are justified in the conclusion that the chromosomes of every cell throughout the whole life cycle may be regarded as the linear representatives, if not the actual descendants, of those present in the original fertilized egg.

Let us now briefly consider some of the characteristics of these bodies. It was formerly supposed that the chromosomes in a given species were all alike, both in structure and in physiologic quality, but we are now able to say definitely that this view was erroneous at least in some measure. In many species the chromosomes show constant differences of size so that certain ones may be recognized by the eye in many successive generations of cells. With these individual differences of size are correlated in some cases characteristic differences of individual behavior at certain periods of the life cycle. It has been shown experimentally that when a combination of chromosomes are artificially produced (for instance by double fertilizing of the egg) that the place in the offspring and similar facts have led to the chromosome of the same nucleus.

ologic characters, playing different rôles in the metabolism of the cell and hence in development. It is but a step from this result to the conclusion that the primary factors of heredity (which, as we have seen, are believed to have their seat in the nucleus) are in some fashion distributed among the chromosomes. It must be admitted that we have as yet but little direct and specific evidence that such is actually the case. The principal argument is part of a more general one that the basis of heredity is contained in the nucleus, and that the chromosomes form the most essential part of the nuclear substance.

THE RELATION OF SEX TO THE CHROMOSOMES

But there is one interesting fact that bears directly on this question. It has recently been found that in some of the insects there is a particular chromosome (known as the "odd" or "accessory" chromosome), distinguishable from the others by its size and mode of behavior, that is in some way related to the character of sex, for all the other chromosomes are paired in both sexes, while this particular one is single in the male, but in the female is accompanied by another similar chromosome. The precise nature of the connection between this chromosome, or pair of chromosomes, and the sexual characters is not yet known, but it is difficult to escape the conclusion that it has to do in some way with the transmission and development of those characters. If this be correct, we have a definite basis for the assumption, by analogy, that other chromosomes are concerned with the transmission and development of other characters.¹

COMPOSITION OF THE CHROMOSOME GROUPS

We may now examine the general composition of the chromosome groups more in detail. One of the most striking discoveries of cytology is the fact that every nucleus contains a double series of chromosomes, that is, two series of chromosomes in duplicate. The fact has already been referred to that the chromosomes often show constant size differences. In all cases in which these differences are clearly marked it may be seen that there are always two of a kind, so that the chromosomes may be paired off two by two according to their size, in other words, if the chromosomes be arranged in the order of their size it is found that they fall into two similar series, the members of which correspond each to each. This fact has not as yet been shown clearly in the cells of higher animals, but it appears unmistakably in the cells of certain lower ones, such as the insects. Nevertheless, there is strong reason to believe that, even when the fact is not evident to the eye, the chromosomes of all cells, with certain special exceptions that only emphasize the rule, form two such duplicate series. The confidence with which we may draw this conclusion rests on the manner in which the two series are known to be produced.

Both observation and experiment have shown with great clearness that the explanation of the double series of chromosomes lies in the fact that they are descendants or representatives of two series that are originally brought together in the fertilization of the egg. Now these two original series are derived from the nucleus of the egg and of the spermatozoon, respectively, and hence are ultimately of maternal and paternal origin. Since every chromosome divides into two at the first division

of the egg, and at every subsequent division, the two daughter chromosomes in every case passing, respectively, to the two daughter cells, it follows that the chromosomes of all the cell nuclei are of maternal and paternal descent in equal numbers.

This conclusion, first reached by pure observation, has received a most convincing confirmation by means of experiment. For example, Moenkhaus was able to effect a cross between two species of fishes, *Fundulus* and *Menidia*, that agree in the number of chromosomes (approximately 36), but differ markedly in respect to their size, the chromosomes of *Fundulus* being nearly three times the size of those of *Menidia*. The resulting hybrids were reared up to a well-advanced stage of development (though not to the adult condition), and at every stage the two forms of chromosomes could be recognized—half (18) of the *Fundulus* type and half of the *Menidia* type—and with such clearness that the difference was distinctly shown in photographs. Similar results have been obtained in a few other cases, though none are as striking as the one described.

If may, therefore, be taken as at least highly probable, if not fully established, that every nucleus of an organism of sexual origin is a dual one and contains representatives of the original maternal and paternal chromosomes in equal numbers. It is evident that we may have here a general basis for the facts of dual inheritance from the two parents. But our conclusion may be pushed much further than this. The pairing of the chromosomes according to their size can apparently mean nothing else than that one member of each pair is a maternal representative, the other a paternal, that is, that every chromosome derived from the egg is accompanied by a corresponding or duplicate one derived from the spermatozoon. If, then, we have any right to assume that the chromosomes differ specifically in their relation to heredity, if we may assume that each chromosome stands in some way for a particular character or group of characters, then the further assumption seems justified that each such character or group of characters has a double basis or determinant, one derived from each of the parents. On the basis of these assumptions may be worked out at least a partial explanation of Mendelian inheritance, as was first shown by Sutton and Boveri.

RELATION OF THE MENDELIAN PRINCIPLE TO CHROMOSOME CHARACTERISTICS

Let us consider the case of an organism having eight chromosomes. In the fertilization of the egg half these chromosomes, which may be designated as A, B, C and D, are derived from the nucleus of the egg, while the spermatozoon supplies four corresponding ones that may be designated as a, b, c and d. The fertilized egg accordingly contains the double series A, B, C, D, a, b, c and d. Since at every division of the egg and its descendants each of these chromosomes also divides, all the cells derived from the egg contain a double series identical with that present in the original fertilized egg, and, as in the egg, they form four pairs, A and a, B and b, C and c, D and d, each consisting of a maternal and a paternal member. This mode of development continues throughout the whole life of the organism up to a period that shortly precedes the final ripening of the germ cells that are to produce a new generation. At the beginning of this period, known as the maturation period, a process, known as synapsis, takes place, in the course of which the chromosomes unite two by two, coupling or pairing so as to form double chromosomes, known as bivalents. As a result of this process the double series of single

¹ It has been shown that the odd chromosome is present in one half of the spermatozoa and lacking in the other half and the facts seem to leave no escape from the conclusion that spermatozoa in which it is present produce females, those in which it is lacking males.

chromosomes present before synapsis gives place to a series of double chromosomes or bivalents, the number of which is, of course one-half the original number of single chromosomes. The remarkable feature of the synapsis is that it is effected by a coupling or pairing of chromosomes that correspond in size, and for the reasons already given this must mean that synapsis involves the coupling of corresponding paternal and maternal chromosomes (as was first pointed out by the American cytologist Montgomery). Reverting to our graphic formulas, in synapsis the eight chromosomes A, B, C, D, a, b, c, d, couple to form the four bivalents A-a, B-b, C-c and D-d. Before synapsis takes place the paternal and maternal chromosomes show no regular or constant relation to one another in the nucleus. After synapsis an orderly regrouping has taken place, each chromosome of maternal descent having paired with its mate or fellow of paternal descent. This process is followed by a long period of growth, in both sexes in the course of which the germ cells prepare for the final act of their maturation. This consists of two rapidly succeeding cell divisions, which in the female lead to the formation of two polar bodies and in the male to the production of four spermatozoa. In one of these divisions, known as the reduction division, each bivalent separates into its two constituent chromosomes one of which passes to each of the daughter cells. It thus comes to pass (and this is the essential point) that after the reduction-division has occurred, half the resulting cells contain one member of each original pair and half contain the other member. This disjunction of each member of a pair from its mate or fellow evidently forms an exact parallel to the disjunction of each dominant character from the corresponding recessive in Mendelian heredity.

It is further clear that owing to the reduction-division, each of the germ cells receives only a single series of chromosomes and hence only half the original number. The particular combination of chromosomes in the reduced series will depend on the manner in which the bivalents divide with respect to one another. If they are all placed in the same position (as in Table 4) the re-

TABLE 4

A	B	C	D	{	A	B	C	D
a	b	c	d		a	b	c	d

sult will be to divide the double series into the original paternal and maternal ones, A, B, C, D and a, b, c, d. The cytologic facts do not in themselves give any direct evidence on this point but we are led by the facts of inheritance to assume that such a mode of division is unusual, though it may take place. It is assumed, rather, that each bivalent divides independently of the others as shown in Table 5 so that any combina-

TABLE 5

A	B	C	D	{	A	B	C	D
a	b	c	d		a	b	c	d

tion of the original paternal and maternal chromosomes may be produced so long as the complete series A or (a) to D or (d) is maintained for example, A b c d a B, C d a b C d A, b c d a b c d and so on. It is evident that the chance combinations of four chromosomes will be the same as those of four characters and similarly with a greater number.

Now, it is too evident to need explanation that all this runs parallel in the most exact and detailed way to the behavior of the unit characters in Mendelian heredity. Just as two corresponding characters (such as two colors) of maternal and paternal origin are associated in a hybrid and as they are disjoined in the formation of the germ cells so two corresponding chromosomes of maternal and paternal origin respectively are associated in the offspring and are disjoined in the reduction-division so that half of the germ cells receive one and half the other. And, again, just as each pair of characters is independent of the others appearing in all possible combinations with them so we may assume that each pair of chromosomes divides without reference to the others and all possible combinations of them (within the limits of the series) appear in the germ cells following the same law of combination as the characters. If we consider a single pair of chromosomes, A and a half the germ cells in each sex receive A and half a. Fertilization according to the law of chances, gives the combinations AA Aa aA and aa in equal numbers which equals $\frac{1}{4}AA + \frac{2}{4}Aa + \frac{1}{4}aa$ or three fertilized eggs containing A (pure or combined with a) to one that contains a only. This is of course the Mendelian ratio and equally well expresses the behavior of the gray and white characters in mice if instead of A and a we write G and W. It is self-evident that the combinations of two or more pairs of chromosomes will be identical with those of two or more pairs of characters giving with two pairs a series of nine terms with three pairs twenty-seven terms with four pairs eighty-one terms and so on.

We have, therefore only to assume that in heredity corresponding chromosomes stand for or are the physical bases of corresponding characters to find a fundamental explanation of Mendelian inheritance and one that is so simple and lucid as to make a singularly strong appeal to our credence.

Had we no other evidence than the fact of the parallelism between the behavior of the chromosomes and that of the unit characters we should be justified in setting up the working hypothesis that the chromosomes play a leading role in heredity but in point of fact there is a great body of independent evidence pointing toward the same conclusion as I have already indicated. Nevertheless we should clearly recognize that the interpretation cannot as yet lay claim to be taken as a demonstrated theory. It is still a working hypothesis only and one whose elements differ considerably in degree of validity. The union of two similar series of chromosomes maternal and paternal in the fertilization of the egg is thoroughly established. It may be taken as highly probable that the double series of chromosomes present in the cells of later stages are linear representatives of the two original series—whether their actual descendants can not be so positively asserted. The pairing of the corresponding chromosomes in synapsis and their subsequent disjunction in the reduction division seems to be well established in certain cases but whether that is always so is an open question that is now undergoing close scrutiny by cytologists. The fundamental assumption that corresponding chromosomes bear or stand for corresponding characters is still a pure hypothesis though one in favor of which a strong argument can be made independently of the facts of Mendelian heredity.

Space will not allow of a more critical examination of these cytologic questions. I will only refer briefly to the interpretation that the chromosome hypothesis has to offer of certain exceptional or difficult cases including non-Mendelian heredity. The most familiar of these

phenomena is that of blended inheritance, such as the cross between the negro and the white man, which produces a yellow or brown type of uniform color which does not break up in the succeeding generation into black and white. It is possible that in such cases the chromosomes that couple in synapsis completely fuse to form true hybrid chromosomes. It is equally possible that without actually fusing in synapsis they become so long and intimately associated as to undergo mutual modification of their substance that brings about the same result.

Many cases have recently been brought to light of partial or imperfect dominance, in poultry, for instance, as has been shown by English and American experimenters, white plumage usually dominates over colored, yet the hybrids often show more or less of an admixture of the colored type, and a similar result has been reached in the case of crosses between crested and non-crested 'owls. When such partial or diminished dominance occurs in the first hybrids it is easily explained by the supposition that one chromosome does not completely inhibit the activity of the other. To explain the results in later generations this will not suffice, and we must assume, as in the case of true blended inheritance, that, either during synapsis or during the long period of association that precedes, the chromosomes permanently affect one another so as no longer to be pure.

An apparent difficulty presented by the hybrid mice and by parallel phenomena in the case of hybrid sweet peas and stocks has, on further study, proved to be perfectly explicable by the Mendelian principle, and at the same time throws an interesting light on certain phenomena of reversion and atavism. In case of the mice, albinos that have been mixed with colored forms and again "extracted" may have acquired the power to transmit that color to their descendants when crossed with mice of certain other colors, yet under the original Mendelian assumption they should be pure. Cuénot has ingeniously explained this by the hypothesis that the production of color requires two factors, which we may call the "color producer" (C) and the "color determiner" (G B Y, etc). The colored gray mouse contains both these factors (C G), the corresponding albino contains the gray determiner (G), but the color producer is absent (hence A G). If these two factors be assumed to couple and disjoin like any other pair of Mendelian characters, the behavior of the albino mice is explained by Mendel's principle. Thus, the appearance of gray depends on the presence of both the color determiner (G) and a color producer (C). The gray mouse possesses both these factors (C G). A mouse in which G is present but C absent (A G) is white or albino, but if such a white mouse be crossed with a black mouse (C B) the offspring will be gray (A G C B) thus "reverting" to a gray ancestor, because the introduction of the factor C enables the color to develop, but gray alone appears because this color is dominant to black. Here the hybrid mice appear to "revert" to a gray ancestor, from which the albino was descended. That this explanation is correct in principle is proved by the accuracy of the predictions that it renders possible, as in the more complex example heretofore considered. A similar explanation is applied by Bateson to explain the behavior of certain white varieties of sweet peas and stocks, which breed true so long as each variety is paired with itself only but immediately produce purple flowers when the two white varieties are crossed. Each of the white varieties is assumed to possess but one of the two-color factors, hence no color develops. Their union by crossing

brings the two necessary factors together and the color at once appears. In this case, too, there is reason to believe that the wild ancestral form was colored. The white varieties represent forms in which one or other of the color factors has been lost. When the two are again united by crossing the hybrids "revert" to the ancestral type, i. e., exhibit a form of atavism. It should be pointed out, however, that this ingenious and plausible hypothesis seems to fail as applied to piebald or spotted forms, for which only a partial explanation has thus far been found.

I will only mention one other departure from the typical Mendelian phenomenon for which the chromosomal theory may give a physical explanation. It is not uncommon to find that the combinations of two or more characters do not follow the simple arithmetical series expected on the law of equal chances, certain combinations being in excess and others correspondingly deficient. This is clearly due to a tendency, more or less definite in different cases, for certain characters to "couple" or accompany each other—either constantly or in a marked majority of cases. In sweet peas, for example, Bateson has shown that there is a marked tendency for round pollen grains to be coupled with red flowers and long pollen grains with purple. In some of the moths, again, in some kinds of crosses certain of the characters of one parent always or usually appear in the male, others in the female, that is, there is a coupling, complete or incomplete, of these characters with the sexual characters. A close parallel to these phenomena has been found in a corresponding coupling of the chromosomes, which tend to cohere in a definite way that can actually be followed out under the microscope. We do not yet know whether such chromosome coupling is really the explanation of the character coupling for the two phenomena have not yet been worked out in connection with each other in the same species. But no one can deny that the one phenomenon seems well calculated to explain the other, and we may here possibly be able to find a decisive test of the whole chromosome theory.

Time will not admit of our following out these problems more in detail. I would not give the impression that they have been completely solved. For some of these problems not even an approximate explanation has been found. But I hope I have been able to show that the cytologic study of heredity is not a vague search after intangible and obscure things, but is engaged with clearly marked, definite phenomena that can be as accurately studied as the phenomena of heredity, to which they run so closely parallel. We should not make too ambitious a claim for the results already attained. It is possible that we are on a wrong track and are dealing with only a complex and detailed coincidence. I repeat that we are not dealing with a fully grounded or well established theory, but only with a working hypothesis. But even so regarded, it is one of the most interesting and suggestive attempts to solve a complex and difficult problem that modern biology can show and as such it merits, I believe, the most attentive further examination.

THE BEARING OF CYTOLOGIC STUDY ON OTHER SUBJECTS

It may be asked in what way the conclusions I have endeavored to outline may offer specific suggestion to the physiologist, the pathologist or the physician. I fear no very satisfactory reply can as yet be given. Still, it may not be amiss to say that if there be any considerable measure of truth in the conclusions I have indicated the law has gone by when the physiologist could allow himself to consider the relation between nucleus and cell

body as the simple reaction of two simple cell organs. He must squarely face the probability that the nucleus is itself a complex organism, as he must also admit that the cell body consists not of one protoplasm but of many protoplasms. Cytologists are laboriously endeavoring to ascertain in what measure the chromosomes are qualitatively different in respect to the processes of growth and differentiation. If such qualitative differences are definitely proved to exist, a new and great field will be opened in cellular physiology and pathology. Already attempts have been made to bring the facts of tumor formation and the like into relation with disturbances in the chromosome groups. I have stated that false combinations of chromosomes have been experimentally shown to lead to false forms of development. So far as I am aware, attempts to find a similar explanation of perverted growths in the body have thus far been without positive results, though some interesting suggestions in this direction have been offered. But it should not be forgotten that in nuclei which show little or no visible differentiation of the chromosomes profound changes might take place without giving visible sign of their presence. Such changes might be immediately induced by any one of many conceivable causes—by parasites, perverted forms of metabolism, the presence of specific forms of toxins and so on—and having once arisen might persist for an indefinite number of cell generations long after the initial exciting cause had passed away. It is still an open question whether the cell is able to regulate the character of the chromosome groups after disturbance, but on the whole such evidence as we have lies on the negative side of the question. Certainly there is nothing more surprising than the stubbornness with which abnormalities in the chromosome groups, when once they have arisen, are perpetuated generation after generation so long as they do not lead to multipolar division. Such an abnormality once arisen even in a single epithelial cell might therefore lead to an extensive pathologic growth of definite histologic character, in which we might seek in vain for a visible causative agent. I fear however that cytology is not yet in a position to bring much help to the pathologist, for we are still too ignorant of the mechanism of normal differentiation to have much to say about that of abnormal forms. It is my impression that this problem can not at present be successfully attacked in the case of the higher animals and that we must for a time be content to rely on the study of much lower ones, such as the insects, where for some unexplained reason the differentiation of the chromosomes is far more clearly shown.

In conclusion I wish to repeat that whether we are on the right track or not in these cytologic studies they stand on a perfectly concrete definite and intelligible basis and can be put to the test of observation and experiment. The facts of heredity have always stood among the most wonderful and apparently mysterious phenomena of organic nature. It is no wonder if they long seemed inexplicable and if some naturalists have regarded, perhaps still regard, the hope of discovering their mechanism in detail as chimerical. To-day I believe this attitude can only be taken by those who have not closely followed the remarkable lines of inquiry that I have endeavored to sketch.

Naming of Carbon Compounds—Thiol. This is a plur-alcohol. These compounds in which the oxygen of the alcohol group is replaced by sulphur thus have thiol as $\text{CH}_3\text{CH}_2\text{SH}$ —*Plur. Thiols*. September, 1906

BACTERIOLOGY OF THE RESPIRATORY TRACT,

WITH ESPECIAL REFERENCE TO INFLUENZA BACILLI *

DAVID J. DAVIS, M.D.
CHICAGO

INTRODUCTION

These studies were carried on with a view of determining the frequency of occurrence of influenza-like bacteria in the sputa and throats of persons afflicted with the various infectious diseases and also of comparing such bacilli for the purpose of determining possible variations which might lead to a subdivision of the influenza group. In a previous paper¹ on the bacteriology of whooping cough I discussed the occurrence of these bacilli in this disease and also gave some data on their occurrence in other infections. Here I shall refer to some of these results and add to them further data on certain properties of these bacilli.

TECHNIC

The technic used in examining the respiratory tract for bacteria was briefly as follows. In nearly all of the cases sputum was obtained in a sterile Petri dish, and as soon as possible brought to the laboratory and examined. In some cases it was impossible to obtain the sputum and throat swabs were used. The sputum, as a rule, was washed in several changes of sterile water or broth and from this washed sputum smears were made and also a small particle was shaken thoroughly in a tube of plain broth for plating. The washing was for the purpose of removing the ever-present saprophytes coming from the oral cavity as the sputum is expectorated. Inoculations were then made from the tube of plain broth into melted plain agar at a temperature of 40 to 42 C., to which about 5 drops of pigeon blood had been added, and this was plated in the usual manner. Pigeon blood was used because it was found that, as a rule, the influenza organisms grow better on this than on other bloods, a fact first noted by Pfeiffer.

WHOOPIING COUGH

In sixty-eight cases of whooping cough, influenza-like bacilli were isolated sixty-one times. In the remaining seven cases they were not found after several examinations. Usually they were found in the first examination, this being true in forty-eight of the sixty-eight cases. In two cases the organisms were found several days before the whoop occurred, but at this time the patients had a severe cough and expectorated much mucus. Examination in six cases during the early stages before the whoops began failed to reveal the organisms. Later when the spasms appeared the bacilli were found. They may remain in the throat for a considerable period of time even after the spasms disappear. During the paroxysms they are coughed into the surrounding air in large numbers as may be shown by holding blood agar plates before the child while coughing. In some cases the bacilli are extremely numerous and on the plates are in almost pure culture while in other cases they are relatively few in the culture. In the negative cases where opportunity was afforded for a search both by smear and culture failed to reveal the organism. In one of the cases, M. J. J.,

catarrhalis was found in nearly pure culture, in several others streptococci were especially numerous

It is sometimes true that in the early spasmodic stage the influenza-like bacilli can not be found, and later they may appear suddenly in large numbers. In two cases this fact was especially conspicuous. Both were in the third week of the disease and had very violent spasms of coughing with typical whoops. Several examinations of sputum at intervals of two or three days both by smear and culture failed to show any of the bacilli, but many streptococci. Suddenly the bacilli appeared in the sputum in large numbers and thus continued

Smears made from the washed sputum and stained by Gram's method with counterstain of dilute carbol-fuchsin show, as a rule, a large number of the small non-Gram-staining influenza-like bacilli. This is not an absolutely reliable means of detecting them, one may become very suspicious of their presence by smear examination, but further confirmation should be made by means of culture

Pneumococci were found in every specimen and were about in the same proportion as in normal throats. Under this term are included those colonies which appear in the plates with a greenish halo about them. Streptococci were found in nearly every specimen of sputum examined. In a number of cases this group of organisms was very abundant and even more numerous than those of the pneumococcus group. As a rule, they were few, not more than three or four colonies on a plate. Compared with the normal, this class of organisms was somewhat more prevalent. The *Micrococcus catarrhalis* was found in large numbers in some of the cases, and organisms belonging to the diphtheria group were found in eight instances. Several strains were given to Miss Hamilton, for identification, who found some of them to be true diphtheria bacilli and other strains to be pseudo forms, they were never found in large numbers. In one case a child had a typical case of whooping cough with no evidence of diphtheria. A swab obtained from the throat showed numerous influenza organisms, but no diphtheria bacilli in smear or blood agar plates. Five days later the patient appeared with a well-developed membrane showing on examination many typical diphtheria bacilli together with some influenza bacilli.

MEASLES

Twenty-three cases of measles were examined, in nearly all of which sputum was obtained for this purpose. They were examined during the stage of eruption and had, as a rule, the cough so frequently present early in this disease. In thirteen of these cases the influenza bacilli were isolated, in four they were the predominating organism, being found in almost pure culture in washed sputum. In some of the other cases they were very few. Pneumococci were always present and about to the same extent as found in normal throats. Streptococci were numerous in a few cases but, as a rule, much less so than pneumococci. The *Micrococcus catarrhalis* was found in ten cases, in two of these it was very abundant, being more numerous than any other organism present. Influenza bacilli were not present in these two cases. Typical diphtheria bacilli whose colonies possessed wide hemolytic zones were obtained in two cases, they were not numerous. Five of the cases were complicated with otitis media. In one of these cases only were influenza bacilli found in the discharge, they were present in very large numbers and in nearly pure cul-

ture, a few streptococcus colonies appearing with them. About ten days previous to this, examination of the sputum showed the presence of influenza bacilli in considerable numbers. Another examination of the ear discharge was made eleven days later. At this time the influenza bacilli were no longer present, but there was obtained, in almost pure culture, a diphtheria-like organism. In a second case a double otitis media developed, and in culture from the ear discharge were found numerous streptococci, a few diphtheria bacilli, a few staphylococci and also a few typical pneumococci which fermented inulin and gave a green colony on blood agar. From the other three cases of otitis media streptococci were obtained pure in one of them, and diphtheria bacilli mixed in the remaining two. One of the cases of measles during convalescence had a profuse nasal discharge. Cultures of this material showed pneumococci, streptococci, a few diphtheria bacilli and also influenza-like bacilli. About a week later there developed a pus infection of the upper lip extending into the left cheek. Both smears and cultures from the pus showed a pure growth of *Staphylococcus pyogenes aureus*.

These results show the large number of varieties of bacteria that may be found in such cases. Streptococci seem to be the most frequent invaders, but the lesions can not be attributed to any one specific organism. The tissues appear to be so non-resistant that any variety that may happen to be present in the upper respiratory passages may find therein a suitable place for growth.

VARICELLA

Eleven cases of varicella in young children were examined. Some of them were in the early stages, others later in the disease. Practically all had a slight cough. Influenza-like organisms were isolated in seven of the eleven cases, in two they were very numerous. Streptococci, few in number, were found in eight, diphtheria bacilli in one, and *Micrococcus catarrhalis* in all. These latter organisms were very numerous in two cases in which influenza bacilli were absent. The greenish pneumococcus colonies were found in all cases and about to the same extent as in normal throats.

MENINGITIS

Opportunity was afforded to examine three cases of epidemic meningitis in children. In the nose in one case was found an influenza-like bacillus. Meningococci were isolated in two of the three cases from the nasal mucosa where they occurred in large numbers. All of them showed some nasal symptoms. One of these cases developed a double otitis media. Streptococci and diphtheria bacilli were isolated in culture, but no meningococci. This case, early in the disease, had a purulent conjunctivitis from which a typical meningococcus was isolated. The conjunctivitis completely disappeared in a few days on boric acid irrigation, leaving no serious result. Another case of interest may be mentioned here. A child 8 years old came into the hospital with the diagnosis of meningitis. She was in coma, the temperature ranged from 102 to 104 F, marked rigidity was present not only of the muscles of the neck and back, but also of the limbs and especially of the jaw. Spinal puncture was made with negative results. Swabs from the nose showed nearly pure culture of diphtheria bacilli and a few were obtained from a throat swab. Antitoxin was administered. In thirty-six hours the temperature was normal, and the child made a rapid recovery. During convalescence otitis media developed, and in the discharge were isolated numerous diphtheria bacilli and

streptococci. This case illustrates the importance of nose and throat examination in infections generally.

INFLUENZA BACILLI IN OTHER INFECTIONS

In order to show the prevalence of influenza bacilli, some data will be given on the occurrence of influenza bacilli in adults in other infections. In twelve cases of bronchitis they were found in the sputum five times, in seventeen cases of typical clinical influenza the bacilli were only found three times. In twenty normal throats of adults they were found twice, but not in large numbers.

From the above data we conclude the organisms of the influenza type are very commonly found in the throat in various infectious diseases. In whooping cough they are found in nearly every case some time during the course, often as soon as the whoop begins or slightly before and again not until some time after the spasms occur. In measles they occur very commonly and early in the disease, that is, within the first three or four days. There also generally appears to be an increase in the number of streptococci in both these diseases over that in the normal. Otitis media complicating infectious diseases is due to a variety of organisms, of which the influenza bacilli may be one, but organisms of the streptococcus and diphtheria group are more frequently responsible. Some of the latter organisms are true diphtheria, others appear to be pseudo forms (Hamilton).

The *Micrococcus catarrhalis* is an organism whose significance is rather difficult to interpret. It is a non-Gram-staining diplococcus, practically indistinguishable from the meningococcus in its morphology, but differs essentially in cultural and other properties. It is not uncommon to find organisms of this kind in the normal throat and nose, but, while sometimes quite abundant, they are seldom the predominating organism. In whooping cough they are commonly found in the sputum, though it must be said it is very rare to find them as the predominating organism. In measles and varicella they are even more common and occasionally are found in large numbers and to the exclusion largely of other organisms. It appears probable that they are increased in all infections of the respiratory passages, but it is difficult to say just how much they have to do in producing the symptoms. That they may play a part in some cases can hardly be questioned, and in support of this a few cases will be cited in which this organism occurred in almost pure culture.

A young man entered the hospital with marked bronchitis and laryngitis, accompanied with almost complete loss of voice. He expectorated considerable mucus and this material washed in sterile water gave an almost pure culture of *Micrococcus catarrhalis*, smears of the sputum showed the same organism. This condition turned out to be the initial bronchitis of typhoid fever. Butler reported before the Chicago Medical Society, an epidemic occurring in young infants at the Maternity Department of the Presbyterian Hospital of Chicago, characterized by the occurrence of fever and laryngeal and bronchial symptoms. Of these cases one patient died and came to autopsy. There was a broncho-pneumonia present and a large amount of purulent mucus in the trachea and bronchi. In both smears and cultures of this material the predominating organism by far was a typical *Micrococcus catarrhalis*. In this case, however, there were also a few pneumococci and their presence makes it difficult to interpret the significance of the former organism. Many of the micrococci were inside the

leucocytes, showing that they are readily susceptible to phagocytosis. Examination of the blood and other body fluids for bacteria gave negative results.

In a third case the patient had, following an ordinary cold, a persistent choking cough which continued for a number of weeks. The cough was very distressing, especially at night and caused the patient to lose sleep. Otherwise she was well. A small amount of thick mucus was expectorated and this chiefly in the morning on rising. Examination of this sputum washed in sterile water gave an almost pure culture of *Micrococcus catarrhalis*. The same result was obtained at two different examinations at an interval of about ten days.

M. Kirchner,² in 1890, observed this coccus in patients with influenza and associated it with the etiology of the disease. R. Pfeiffer cultivated this germ from the sputum in a variety of infections of the respiratory tract and gave it its present name. Ghon and H. Pfeiffer³ found it eighty-one times in 140 cases of respiratory affections, they considered it usually saprophytic but capable of producing at times acute or subacute lesions. It has been found by many others, especially in the respiratory tract in various infections of children, and has been associated with the cause of pertussis by Ritter and Buttermilch.

From the above data and the reports of others it appears that the *Micrococcus catarrhalis*, though frequently present as a saprophyte in the normal respiratory passages, is often associated with various kinds of inflammatory conditions in this region, especially in children. It can not be considered a specific organism for any particular characteristic group of symptoms, but appears to act as a common invader secondary to a variety of specific diseases. The possibility of its being a primary invader at times and under certain conditions seems reasonable.

The occurrence of the influenza bacilli in so few of the cases of clinical influenza or grippe is worthy of some comment. These cases were all diagnosed clinically as acute influenza and were typical in their symptomatology. The sputum was obtained early in the disease and in almost every case the plates were characterized by the relatively large number of streptococcus colonies present. In those cases in which the influenza bacilli were found they were not present in especially large numbers. It is undoubtedly true that most of the cases reported as clinical influenza, at least in recent years, are not influenza infections at all but are infections with other organisms, principally streptococci and pneumococci and perhaps also the *Micrococcus catarrhalis*. It appears to be true that a number of organisms can produce practically an identical clinical picture, and this has come to be known as influenza or grippe since the great epidemic of 1889-90. By many, such cases are assumed, without a bacteriologic examination, to be infections with the influenza bacillus, whereas in reality, as the above data, as well as many recent reports in the literature indicate, the cause is usually due to other organisms, the most common of which is undoubtedly the streptococcus.

The significance of the influenza bacilli found so frequently in the throat in infections of various kind deserves some comment. These bacilli have a low degree of virulence for animals. If very large quantities are injected into the peritoneal cavity of guinea-pigs the animal dies in twelve to twenty-four hours and the

bacilli may be recovered from the blood. Attempts to evaluate their virulence have not been very satisfactory.

Finding them occasionally in normal throats indicates the possibility that they may exist as harmless saprophytes or as organisms with a potential pathogenic function awaiting an opportunity favorable for development. That they are not always harmless saprophytes is shown by the fact that bacilli isolated from whooping cough and transplanted in the normal mucosa of the human throat will multiply abundantly and produce definite reaction. In one such experiment made by the writer on a young man whooping cough did not develop, but a slight fever lasting for a few days and some throat symptoms occurred, accompanied with the expectoration of a large amount of thick tenacious mucus in which the bacilli existed in large numbers in almost pure culture. We are, therefore, justified in attributing to them pathogenic properties for man, even though they may not be a specific primary cause of disease.

A careful comparison was made of the influenza-like bacilli from the various groups of diseases in which organisms of this type were isolated. This included whooping cough, measles, epidemic meningitis, varicella, clinical influenza, bronchitis, normal throats, and also strains isolated from conjunctivitis, scarlet fever, and tonsillitis. Morphologically and culturally no differences are found which would serve to subdivide them into groups. The organisms from these various diseases agree very closely. Strains from the same disease differ from each other slightly. Some tend to form threads very readily and are slightly larger than other strains, but this was found in all the diseases where a number of strains were isolated. Altogether about one hundred different strains have been tested. Without exception all require hemoglobin media. They are non-Gram-staining, short bacilli and stain more deeply at the ends with methylene blue. In the throat they never form threads, but in culture nearly always a few may be found, and in some strains this tendency is very marked, especially in the older cultures. We may say, then, that these bacilli agree very well with the influenza bacillus as described by Pfeiffer, and the forms showing a tendency to form threads correspond to his pseudo-influenza bacilli which he found in broncho-pneumonia and other conditions. That there is no essential difference between them seems to have been definitely determined by a number of writers, and the result given in this paper also indicate such to be true.

AGGLUTINATION OF INFLUENZA-LIKE BACILLI

In order to show possible differences in the strains of influenza-like bacilli, rabbits were immunized against organisms isolated from whooping cough, measles, clinical influenza, scarlet fever, varicella, tonsillitis and conjunctivitis. The animals were first injected subcutaneously with the living germ and later intraperitoneally with gradually increasing doses. Finally they were injected twice with two agar slants of the living germs intravenously. The animals gradually lost weight, but otherwise showed little effects from the injections. At first they were injected once a week and later twice a week, this being continued for from eight to twelve weeks. The agglutination tests were made by the microscopic method and controlled with the microscope. This is the method of Cantani, Wollstein and others. There was some difficulty at first in getting homogeneous suspensions of the bacilli, but by using young cultures,

preferably from twelve to eighteen hours old, thoroughly agitating them in normal salt solution and then centrifuging out the clumps that may remain a satisfactory suspension was obtained for agglutination purposes. The serum was diluted with normal salt solution and the dilutions 1/10, 1/20, 1/50, 1/100, 1/200, 1/500, 1/1000, and occasionally higher were used. The serum of normal rabbits causes some clumping in all strains at a dilution of 1/10. Occasionally some strains were clumped at 1/20, but never any higher. In the immune animals agglutinins are present at the end of six weeks or earlier. In from eight to twelve weeks they are abundant. The sera in all the animals agglutinated the homologous organism at a much higher dilution than any strain isolated either from the same disease or from another disease. This was true, without exception, in every test made. All the sera agglutinated the homologous organisms in dilutions of 1/500, some at a dilution of 1/1000, and in one instance the serum from an animal immune to an organism from tonsillitis at a dilution of 1/5000. The agglutination of the other organisms varied considerably, but in most instances showed some increase above that obtained with normal serum. As a rule, this varied from 1/50 to 1/100 and occasionally rose to 1/200. Organisms from the same disease as the organism used to immunize, but from a different patient, did not appear to be agglutinated at higher dilutions than organisms isolated from other diseases. Table 1 is given as a fairly typical illustration of the agglutination of these bacilli. Tables showing the agglutination by sera immune against these bacilli from other sources show the same facts as this table and are consequently omitted. In every case, as in the table given the agglutination of the homologous organism takes place with far higher dilutions of the serum than that of any other strain. It appears, therefore, from these results that common agglutinins are developed for all these strains of influenza-like bacilli about to the same extent and on this basis no subdivision of these bacilli into groups can be made.

TABLE 1—AGGLUTINATION OF INFLUENZA LIKE BACILLI BY RABBIT SERUM IMMUNIZED AGAINST A BACILLUS ISOLATED FROM PERTUSSIS

Source of Organism	Dilutions.							Salt Solution Control.
	1/10	1/20	1/50	1/100	1/200	1/500	1/1000	
Pertussis (homologous organism)	+++	+++	+++	++	++	++	+	0
Pertussis (not homologous)	+++	+++	++	+	0	0	0	0
Measles	+++	+++	++	+	0	0	0	0
Conjunctivitis	+++	+++	++	+	0	0	0	0
Tonsillitis	+++	+++	++	+	0	0	0	0
Laryngitis	+++	+++	++	+	0	0	0	0
Varicella	+++	+++	++	+	0	0	0	0
Influenza ..	+++	+++	++	+	0	0	0	0

During the past season so few cases of pertussis in which these bacilli are common were available for examination that studies on the agglutinative property of the sera of patients for these influenza-like bacilli have hardly begun. This subject will be largely reserved for consideration at some future time and only a few statements made here. Normal human serum produces clumping of the strains of bacilli given in Table 1 at dilutions of 1/10 and slightly at 1/20. Practically no difference appears between the strains in this respect. In four cases of pertussis the sera clumped the bacilli from pertussis cases in slightly higher dilutions than those isolated from other sources. These dilutions

varied from 1/100 to 1/200. In one case of "grippe" in which the patient's throat showed these bacilli were very numerous, the serum fourteen days after the onset did not agglutinate the homologous strain or strains from other sources.

PHAGOCYTOSIS OF INFLUENZA BACILLI

Within the last few years a large amount of study has been given to phagocytosis of bacteria and through animal and test-tube experiments considerable light has been thrown on the mechanism of this process. It has been shown by Wright and others that bacteria, as a rule, are taken up by leucocytes only when serum is present. Leucocytes washed several times in salt solution are no longer capable of ingesting organisms, but if serum is added to these corpuscles they promptly regain this property. The serum, therefore, is the important factor in determining phagocytosis, and the particular substance in the serum which causes it has been called "opsonin." A study of the influenza bacillus with reference to phagocytosis was made and the results will be briefly indicated.

Pfeiffer noted the occasional occurrence of these bacilli inside the leucocytes in the sputum in influenza bacilli more particularly in the latter part of the attack. In the sputum in other infections such as pertussis in which similar bacilli are found it is only occasionally that they are encountered inside the pus cells. When the bacilli in moderate quantities are injected into the peritoneal cavity of animals they are taken up in large numbers by the numerous invading polynuclear leucocytes, but if very large amounts of bacilli are injected the exudate contains few leucocytes and the animal dies in 12 to 20 hours. The few leucocytes, however, which may be present under these conditions readily take up the bacilli.

In the test-tube strains isolated from measles, whooping cough, tonsillitis, pharyngitis, varicella, influenza, and conjunctivitis were all found to be readily taken up by human leucocytes in defibrinated blood in the course of twenty minutes or less. If washed leucocytes are used the bacilli are also taken up, but not so rapidly as when serum is added to them. When thick suspensions of bacilli are used in from twenty to thirty minutes the leucocytes in both cases are crowded with them. If dilute suspensions are used in twenty minutes a distinct difference in phagocytic activity between the washed and unwashed leucocytes in favor of the latter is seen, but after from four to eight hours this difference disappears, the leucocytes now being usually so filled with the bacilli that their number can not be accurately determined by count.

This phagocytosis in salt solution, which may be referred to as spontaneous phagocytosis, appears at present at least somewhat exceptional for nearly all bacteria so far tested seem to require the presence of serum for phagocytosis. However, it has been observed by Miss Tunnicliff in this laboratory that abundant phagocytosis of the *Bacillus fusiformis* occurs in salt solutions without the presence of serum and it is also known that carmine particles are readily taken up by leucocytes in the absence of serum. Wright observed spontaneous phagocytosis of tubercle bacilli in certain concentrations of salt solution. The greatest spontaneous phagocytosis occurred in a 6 per cent solution; this progressively decreased and practically disappeared in a 1.3 per cent solution. Varying concentrations of salt at least within the above limits have no effect on phagocytosis of influ-

enza bacilli. This is shown in Table 2. In this experiment a thin suspension of bacilli was used; otherwise phagocytosis would have been so rapid that the bacilli could not be counted in the 20-minute and 2-hour intervals.

TABLE 2.—SHOWING EFFECT OF VARYING CONCENTRATIONS OF NaCl ON PHAGOCYTOSIS OF INFLUENZA BACILLI BY NORMAL HUMAN CORPUSCLES WASHED FOUR TIMES

Concentration of NaCl Solution	Phagocytosis		
	20 minutes.	2 hours.	6 hours.
6 per cent.	5	31	20+
7 per cent.	3	24	20+
8 per cent.	9	48	20+
8.5 per cent.	3	40	20+
9 per cent.	4	85	20+
10 per cent.	1	09	20+
11 per cent.	15	12	20+
12 per cent.	1	80	20+
13 per cent.	.2	38	20+
14 per cent.	.3	89	20+

Spontaneous phagocytosis can not be satisfactorily explained by insufficient washing of the corpuscles. In some of the experiments these corpuscles were washed seven times, and each time there was added many times as much salt solution as there were corpuscles present. This amount of dilution and washing is quite sufficient to completely inhibit phagocytosis of staphylococci and meningococci. In several of the experiments staphylococci and meningococci were used as controls and in no instance were they taken up even after eight hours. Again spontaneous phagocytosis can not be explained by long-continued cultivation on artificial media. Eleven strains isolated from various sources without exception showed spontaneous phagocytosis, though some had been isolated from the throat lesions only a few days, while others had been under cultivation for five months. The possibility of explaining the large numbers of bacilli in the leucocytes after a few hours by growth having occurred inside the leucocyte from an occasional ingested bacillus was ruled out by using bacilli killed by heating to 46 C for thirty minutes. That the bacilli do not become sensitized by growing on blood media which they require was shown by using washed corpuscles in the media and also by heating the blood to 95 C for one hour before adding it to the media. Lastly, spontaneous phagocytosis is not the mere adhesion of the bacilli to the surface of the leucocyte, for its appearance is identical with that of phagocytosis occurring in serum and mere adhesion of bacteria to a leucocyte is manifested by a marginal arrangement of the organisms. We are justified, therefore, I think in considering the influenza bacillus an organism which does not require the presence of serum and which may be classed with such inert bodies as carmine particles. Opsonins, therefore, do not appear to be the only factor which control the ingestion of bodies by leucocytes. The fact should be borne in mind, however, that in the presence of serum this process of phagocytosis is accelerated.

It has been shown for a number of organisms that phagocytosis is more active in immune serum than in normal serum and this has been explained by the increased opsonic content of the former. Experiments to determine this point were made using the sera of rabbits immunized against various strains of influenza or-

7 In the staphylococcus suspension the leucocytes are differentiated to such an extent in the course of a few days that the leucocidin formed by the organisms that phagocytosis can not be determined.

organisms. The results with six sera on eight different strains of bacilli show some variation but it was found that frequently phagocytosis in the immune serum exceeded that in normal serum and in some cases it was marked. There was little if any, difference between the phagocytosis of the homologous organism and other strains from the same or from some other disease.

Some factors enter into the determination however, which make it very difficult, if not impossible, with present methods to obtain an accurate estimation of a possible opsonic increase in the immune serum. As disturbing elements may be mentioned spontaneous phagocytosis which can not be eliminated from the determinations. Another factor to be considered is the agglutination of these bacteria by immune sera. Bacteria in clumps naturally are taken up in larger numbers than in homogeneous suspension, and consequently increase in phagocytosis in agglutinating serum does not necessarily mean increase of opsonin. These facts together with the fact that these bacilli are extremely small staining poorly, as a rule, and would be difficult to accurately count even under the most favorable conditions, render opsonic determination for these organisms with the present methods at least very untrustworthy.

SUMMARY AND CONCLUSIONS

1 Influenza-like bacilli are very commonly found in the upper respiratory tract in various infectious diseases and especially in whooping cough. Occasionally they occur in normal throats.

2 Various organisms occur in the discharge in otitis media the streptococci being the most common, occasionally influenza bacilli are found.

3 The *Micrococcus catarrhalis* is a common inhabitant of the respiratory mucosa in infectious conditions and in some cases exist in nearly pure culture. It does not appear to produce specific lesions.

4 The influenza-like bacillus from whooping cough is pathogenic for man, its specificity is doubtful. Present data permit us to consider these bacilli as secondary invaders in all the diseases in which they are found. A primary invasion at times should be considered a possibility.

5 Influenza-like bacilli are readily taken up in the test-tube by unwashed leucocytes and to a less extent by washed leucocytes. This spontaneous phagocytosis is not affected by varying the concentration of the salt solution between 0.6 per cent and 1.4 per cent.

6 Injection of these bacilli into animals causes the production of specific agglutinins and probably also an increase in opsonins in the serum. Because of the occurrence of spontaneous phagocytosis and agglutination in such sera the determination of the opsonic index for these bacilli is rendered unreliable.

Extraction of Set of False Teeth from the Esophagus— Chiari has recently reported (*Wien Klin Wochschr* xx 147 1907) the successful extraction of a set of 5 false teeth on a plate 4.5 by 2.5 cm, which had been swallowed during sleep. The patient was a man of 39 who awakened suddenly with suffocation and retching which soon subsided, but he could not eat solid food. He had no pain nor fever and several physicians diagnosed cancer of the esophagus. After a month radio-copv revealed the foreign body and it was readily inspected through an esophagus tube after cocaineization. A smaller tube was then introduced and the foreign body was drawn out readily not through the tube but with it. He has found inspection usually possible in such cases as condition that favored swallowing the body also favor inspection.

THE CURE OF HYSTERICAL PARALYSIS BY RE-EDUCATION OF KINESTHETIC CENTERS

HOWELL T. PERSHING, M.D.
DENVER

The sudden disappearance of hysterical paralysis, through religious excitement, hypnotic suggestion or great faith in the assertion of a particular physician, has been made so familiar to the profession that many, no doubt, think of it as the normal and eminently desirable mode of recovery. I have had a moderate share of such cases, sometimes being able, within the clinic hour, to make a patient with hysterical hemiplegia or paraplegia throw away his crutches and run about the room. These spectacular cures are intensely interesting and valuable from the purely scientific as well as from the practical standpoint, and they are within the reach of any physician who is sure of his diagnosis and able to pick out the favorable case.

Nevertheless, the method that aims at such sudden cures is not the one to be generally chosen. It will succeed in only a few of the cases and it stakes too much on the immediate effect of predictions, which, by promptly failing of verification, may prevent future success. Moreover, prompt success may have its disadvantages. Immediate relief from paralysis, which is only one symptom of the hysterical state, may prevent the patient from receiving that enlightenment and discipline which are essential to anything more than a superficial and transient improvement.

As a basis for a better method we must have an explanation of hysterical paralysis that will unite all favorable influences into a consistent plan of treatment. This was impossible a generation ago, but modern neurology can at least furnish a working hypothesis.

Probably the most constant accompaniment of hysterical paralysis is the anesthesia of the paralyzed parts especially the absence of those sensations normally caused by motion. The patient can not feel the motions of the paralyzed limb nor can he think of them, except, perhaps, in visual images. Now this absence of kinesthetic sensations and kinesthetic ideas is not merely a complication. It must necessarily cause paralysis, because every voluntary motion must be preceded by the idea of the motion, and its continued execution must be controlled by an orderly series of sensations aroused by the movements already made.

These sensations and ideas of motion are a function of the sensory convolutions back of the Rolandic fissure. In normal volition these convolutions are first excited (by association impulses from other cortical centers) and then, directly or indirectly, by association impulses, they arouse the corresponding motor centers in the precentral convolution. In sending out these association impulses the kinesthetic centers are subject to facilitation and inhibition through the influence of other cortical centers. All that we know of the mental factors in hysteria favors the view that in hysterical paralysis the kinesthetic center is overwhelmed by a preponderance of inhibitory impulses, incidental to the perverted ideas and emotions. It can not act with sufficient vigor to awaken the idea of what is to be done or to send the necessary association impulses to the motor centers so the limb remains motionless, although the motor centers connecting tracts and muscles are in perfect order. This is in striking contrast to cases of organic paralysis caused by lesion below the cortex, in such cases the

kinesthetic centers being unharmed, the patient retains a vivid idea of the movement desired and often feels that the limb must move or even that it has moved.

If this theory of hysterical paralysis is correct the first object is to awaken the dormant kinesthetic center. This can best be done by a skilful combination of favorable influences, emphasizing now one and now another, according to the needs of the individual patient and the progress of the case. If the improvement is rapid, very well, but if it is slow there is still a definite plan to be followed.

First in time and also in importance is the effort to raise the emotional tone of the patient. It is a familiar fact that voluntary motion is greatly facilitated by exhilarating emotions and powerfully restrained by depressing ones. Mania and melancholia furnish extreme illustrations of the general law and the milder emotional states have a proportionate effect of the same kind. The effort to substitute exhilarating for depressing emotions should be along two different lines, mental and physical.

After the careful recording of the history and thorough examination of the patient, the assurance that there is no organic disease and that recovery may confidently be expected is the best beginning of treatment, and throughout the case success and favorable indications are to be dwelt on and the opposite ignored. Sometimes our first attempts in this direction meet with but scant success, the patient may be apathetic or may even oppose and actively resent our cheerful view of the case. When this attitude is encountered it is well to resort to a device I learned long ago from Dr. S. Weir Mitchell. If the patient is a young woman intimate that you are especially anxious to get her well because her disability would, if permanent, necessarily interfere with her happiness by making her less attractive and possibly subjecting her to ridicule. Usually a mere hint, let fall apparently by accident, will be quite sufficient, and the idea once lodged we should hasten to dwell on the contrasted prospect of a happy life and the pride of health. In the case of a young man or boy an analogous idea may easily be made effective. With children the offer of a reward, to be delivered when recovery is complete or has reached a certain stage, will be better.

The physical measures for invigorating the nervous system and at the same time improving the emotional condition, namely rest, food, tonics and sedatives, are of great importance, but I will not consider them in detail, as physicians are generally far more familiar with them than with the mental influences just considered. I think also that they are on the whole less essential to success. It seems to me that the profession has erred very greatly in thinking of the brilliant results of the rest cure in certain cases of hysteria as due to the physical effects of rest in bed, full feeding, massage and electricity, whereas it is mainly due to the great psychological insight and moral influence of Dr. Mitchell and his successful followers. Nevertheless both mental and physical remedies should be applied in harmonious combination.

While trying to improve both the mental and the physical functions of the brain as a whole we can act specifically on the dormant kinesthetic centers by sensory stimulation. Strong faradic currents, applied to the skin and muscles, followed by vigorous even rude passive motion of the affected joints have a powerful tendency to restore sensations and ideas of motion. The patient must be urged to pay close attention and to

note even the slightest beginning of sensation. In hysterical anesthesia the loss is not absolute. The sensory centers act, although inefficiently, and the sensations are obscurely present, but they are so feebly associated with what is vividly in the field of consciousness that they seem to be absent. Attention to the anesthetic limb and the effort to recognize its sensations tends to bring its cortical sensory centers into relation with all the rest of the cortex and to make its sensations a part of the whole field of consciousness.

Having awakened some degree of normal sensibility, the cure will be completed by exercises in voluntary motion. But preliminary to these any inhibitory fears must be overcome. For example, the patient may say that she not only can not move the left leg, but that merely trying to do so causes a dreadful pain in the head, neck or back. This pain is doubtless purely mental in its origin, but it is nevertheless real (just as nausea excited by the idea and fear of nausea is real) and the fear of pain may excite contraction in the opposing muscles when the patient is urged to move the limb. The difficulty can generally be removed by careful examination of the seat of pain and assurance that no harm can come of the attempt, but that on the contrary the pain will quickly cease to appear if defied to do its worst.

If the paralysis is nearly total the limb should be so placed that its weight will favor the attempted movement. This will assure some motion which the patient sees and can be encouraged to increase. A beginning once made, the extent and strength of the movement can gradually be increased, always giving something concrete to do, such as kicking an object or placing the foot on it, and always ignoring failure and enthusiastically praising success. When some progress has been made definite movements can be assigned for practice in the interval of the physician's visits.

In this way the normal control of the muscles can gradually be approached and the length of time required may be made an advantage by using it to carry on a re-education in composure and self reliance, without which the cure of paralysis will be but a temporary change in the symptoms, not relief from the disease.

I have recently followed this method of treatment with great care in two cases of typical hysterical hemiplegia, and in both cases the clinical facts and favorable results were in perfect harmony with the theoretical considerations here set forth. One patient was a young man whose paralysis followed a trivial railroad injury. There was loss of posture sense and of ideas of motion in the right leg and efforts to move it caused lumbar pain. The arm was similarly affected, but in a slighter degree. In spite of the fact that he was claiming damages and that I saw him at the request of the railroad company, he willingly co-operated with the treatment, and when he left Denver about two months after the accident was almost entirely well. The other case was that of a young woman whose paralysis came on gradually at the end of pregnancy and during the puerperal period after a long series of confinement-debilitating diseases and worries. The left leg and arm were paralyzed with corresponding loss of posture sense and ideas of motion, the leg being worse and the right side was affected in the same way but to a much slighter degree. She walked only with the aid of crutches, dragging the left leg. The paralysis of the leg seemed absolute in the ankle and knee and it was difficult to make any start in voluntary motion. There was also an inhibi-

terical pain After partial revival of the posture sense by means of electricity and passive motion, exercises in moving the foot were begun and progress, although slow, was steady After a time the crutches were discarded and walking was good, with the aid of a light cane A striking feature in this case was the slowness of all voluntary motions in the affected area When the patient left for her distant home, although this defect was still apparent, there had been a great gain in promptness of movement. The gain in appearance, general health and mental vigor was quite as marked as that of voluntary motion

THE UNDERLYING PRINCIPLES OF TUBERCULIN THERAPY *

F M POTTENGER, A.M., M.D

Medical Director Pottenger Sanatorium for Diseases of the Lungs and Throat Professor Clinical Medicine, Medical Department of the University of Southern California
MONROVIA, CAL.

Tuberculin has now been subjected to the test of time It has been in continuous employment for fifteen years It has been used in many experiments on animals and its virtues have been tested on human beings In spite of this mass of laboratory and clinical experience there seems to be but a hazy idea as to what tuberculin is, how it acts, and what it is expected to do

In order to understand the principles which underlie tuberculin therapy we will discuss First, Nature's method of cure in specific diseases, second, conditions which militate against tuberculosis in curing itself, third the manner in which specific inoculations of tuberculin aid in the cure of tuberculosis

NATURE'S METHOD OF CURE IN SPECIFIC DISEASES

When pathogenic microbes gain entrance to the organism certain phenomena take place If the microbes are exceedingly virulent, if the resisting power of the organism is low, or if the microbes gain entrance in great numbers, infection is likely to occur On the other hand, if the microbes are not highly virulent and do not gain entrance in too large quantities and the resisting power of the organism is good, infection will probably be ward off

When pathogenic microbes gain entrance to the body the organism at once attempts to destroy them An increase in the amount of serum and in the number of leucocytes at the point of attack is at once noticed The microbes, on the other hand, begin to multiply and a battle for mastery ensues The microbes during their activity produce a toxin which has a stimulating effect on the vasodilators¹ and cause an afflux of serum to the part If given off in small amounts the toxin stimulates the cells of the organism, which react and form defensive bodies if given off in large quantities the toxin may destroy the cells entirely Thus a slight infection tends to cure itself while a severe one tends to destroy the invaded organism

Several defensive bodies which are produced by the organism have been studied in recent years, such as anti-toxins lysins coagulins precipitins and agglutinins Recently there has been added to these another of great interest the opsonins of Wright and Douglas These investigators have shown that the old humoral theory of

disease is, at least in part, correct The brilliant work of Metchnikoff had almost established the leucocyte as the chief agent in the defense of the organism against infection, but these investigators have gone one step further and shown the poor leucocyte to be absolutely helpless unless aided by the blood serum They have discovered in the blood serum a substance which acts on bacteria and prepares them for destruction by the leucocytes This substance they have called "opsonin"

Through the study of the opsonic power of the blood our knowledge of the phenomena which take place during infection and during Nature's efforts at curing the infection have been materially increased

If an organism is infected by a given pathogenic microbe the power of the blood for destroying that microbe diverges from the normal If the infection is local the opsonic power is persistently below normal, if it is systemic it will vary from below normal at certain times to above normal at other times² However the opsonic power of the blood of an infected organism is naturally low for the specific microbe, causing the infection

In order to cure an infection Nature increases the natural defenses of the body fluids after the manner mentioned above This can be studied with exactness by determining the opsonic power of the blood, especially in systemic infections Every now and then a new amount of toxin will be delivered If the amount is not too great the cells will be stimulated and react, increasing the natural defenses, as shown by a rise in opsonic power, and the patient will improve, or, if the amount of toxin be too great, the opsonic power will be lowered and the patient may be destroyed

CONDITIONS WHICH MILITATE AGAINST TUBERCULOSIS CURING ITSELF

When tubercle bacilli gain entrance to the tissues they at once begin to multiply They give off toxins which stimulate the vasodilators, causing an afflux of serum and leucocytes to the point of attack If conditions are favorable to the invaded organism the bacilli will be destroyed If not the micro-organisms become surrounded by leucocytes, proliferation of the fixed cells takes place, and the bacilli are shut in A tubercle is formed as a result of Nature's conservative effort to wall off the bacilli

But this very conservatism proves an injury and defeats its own purpose As the tubercle increases in size the blood supply to its interior is shut off Toxins are liberated by the bacilli, and this poorly vascularized tissue breaks down, the center of the tubercle softens These toxins if set free into the blood stream in the proper quantities would stimulate the cells of the organism to the formation of defensive elements, and thus heal the lesion, but they are liberated at irregular intervals and in varying quantities, consequently their value as curative agents is interfered with

Another thing must be considered The tubercle bacillus is surrounded by a dense envelope which prevents it from giving off its toxins freely, infection, therefore, can occur without the cells of the organism having received sufficient stimulation from the bacilli to materially increase the natural defenses In tuberculosis, then, there is a failure on the part of Nature to supply the stimulation necessary to bring about a cure If the natural defenses of the organism are sufficient

either infection does not occur or healing takes place, but if any considerable aid is required a cure does not result.

One other factor which prevents a cure in tuberculosis is the tendency for the disease to spread. As stated above, the natural defenses of the organism infected by tubercle bacilli are reduced. When tubercles soften and break down bacilli are liberated. They may pass out through the air passages or they may be set free in the tissues and tend to cause a new focus. The conditions are nearly always favorable for infection to take place, resisting power low, blood poor in defensive bodies, and not able to freely enter the parts where infection is starting. If these bacilli were to pass into the blood in not too great quantities at a time so that they could be freely acted on infection would not be so common, but instead they pass into adjacent lymph spaces where conditions are most favorable for infection to take place. In fact, we may assume that infection takes place in favorable locations as a rule, as Wright² so well expresses it.

I conceive that these micro organisms are cultivating themselves under conditions which do not even remotely resemble those which they would have to confront in the circulating blood. In the case of bacteria in the actual blood stream all the antibacterial elements of the organism would come into application on them. In the case of bacteria cultivating themselves in the tissues, only those antibacterial elements would come into application which had passed out from the blood in the lymph in the region of the infection. Further, inasmuch as lymph, coming in contact in succession with a number of bacteria, or as the case may be, with their products, would part with its antibacterial elements to those first encountered, retaining after percolating through a first bacterial nidus to a second, or through the outer portion of such a nidus to its interior, a residual trace only of its original antibacterial power, there would come into existence, in particular in the case when the lymph flow stagnated in the tissues, conditions far more congenial to the cultivation of bacteria than those which obtain in the blood.

HOW TUBERCULIN AIDS IN THE CURE OF TUBERCULOSIS.

As previously stated, Nature's method of cure in infectious diseases consists in the organism producing defensive bodies in response to stimulation from toxins engendered by the specific microbe which causes the disease in question. Attention was also called to the fact that in tuberculosis, owing to the nature of the bacillus and the character of the tubercle, this specific toxin which stimulates the cells to the formation of anti-bodies fails to gain access to the blood in proper quantities and at the proper intervals to be effective. In this connection it should be remembered that too great stimulation is harmful and will defeat Nature's own purpose. That the blood is deficient in protective substances is shown by the measurement of its opsonic power. This is, as a rule, below the normal standard, although there are exceptions which remain to be explained.

Bulloch,³ assuming that the opsonic power of his own blood is normal compared to that of 84 healthy people with it. Counting his own as one the index of the 84 averaged 96, and varied from 8 to 12. From these experiments we assume that the opsonic power of the blood of healthy individuals toward the tubercle bacillus varies from 8 to 12.

In 150 cases of lupus tested by the same author the average opsonic index was 75 and the manner in which the various cases had responded to treatment was in

accord with the index. Those which had done badly showed a low index, while those that had responded to treatment showed a higher index. That the opsonic index in those patients suffering from tuberculosis can be raised by the injection of tuberculin has been thoroughly established by Wright,² Bulloch,³ Lawson and Stewart⁴ and others.

Lawson and Stewart⁴ demonstrated what can be done by injections of tuberculin in raising the opsonic index. They measured the index in twenty-four patients who had undergone the usual open-air sanatorium treatment for periods varying from one month to two years and three months, and whose indices were 80 and below, in twenty out of twenty-four cases. Within a period of six weeks during which inoculations of tuberculin were given the indices of these patients went to normal or above normal in all but one case, as is shown in the following tables taken from the paper quoted.

4. A Study of Some Points in Relation to Tuberculin. Lancet, Dec. 9 1905

3 The Treatment of Tuberculosis by Tuberculin. Lancet, Dec. 2, 1905

This is in harmony with the observations of Koch,⁵ Moeller⁶ and others as regards the increase of the agglutinating power of the blood after the administration of tuberculin. This increase of the agglutinating and opsonic power of the blood means that the natural defenses of the organism have been increased. The organism has been given greater power to combat the disease than before. In Table 1 the average opsonic index is shown to be .75 during ordinary sanatorium treatment, and in Table 2 it appears as 1.19 after tuberculin has been added. Thus the power of the organism to combat the disease as measured by the opsonic power of the blood was increased 58.6 per cent by the addition of tuberculin.

The importance of this can be seen in this way. The opsonic power is that power of the blood serum which prepares the bacilli to be destroyed by the leucocytes. In the above tables the leucocytes of those cases which were treated by ordinary sanatorium methods (Table 1) were able to destroy only 75 per cent of the number of tubercle bacilli that a normal person's blood should destroy, while the leucocytes of the same patients (Table 2) after treatment with tuberculin were able to destroy 19 per cent. more than the leucocytes of a normal individual.

The value of this increase of the natural defenses of the organism is evident. When we remember that the one reason why tuberculosis kills is because of its tendency to spread to new tissue, either adjacent or distant, we can readily understand how great an advantage those patients enjoy who have their body fluids well charged with defensive bodies, ready to attack and destroy the bacilli as soon as they come in contact with them. If the body fluids are rich in antibodies a small outbreak of bacilli into a new area would doubtless soon be cared for, while a large number might cause an infection, yet we can conceive of so many more of the germs being destroyed by a highly defensive body fluid than by one poor in defensive bodies that the infection could not help being favorably influenced, even if not prevented.

It has long been claimed by men familiar with tuberculin therapy that the disease shows much less tendency to spread in those cases treated by it than in those treated by ordinary methods. In the light of these new discoveries in immunity and immunizing treatment this is easily explained. This immunizing action of tuberculin is not its only method of aiding in bringing about a cure. Tuberculous areas are naturally very slow of healing. Tuberculin when administered in proper doses and at proper intervals furnishes a stimulation for these areas which hastens healing by stimulating the formation of fibroid tissue. Theoretically, then, tuberculin has a firm foundation on which to stand. Now let us turn our attention to its clinical workings and see if they confirm the theory.

The real test of tuberculin is in pure tuberculosis. After destruction of tissue has taken place, after other organisms have entered the field, after the general constitution has become undermined after consumption has supervened then we should not demand a cure of tuberculin. Nothing short of the elixir of life would be a specific for such a condition. While I believe that tuberculin is of great value in chronic non-febrile cases of tuberculosis yet it is in early cases that we should expect most brilliant results.

In a former paper⁷ I collected data of 1,200 first stage cases of tuberculosis. Of these 611 were treated in sanatoria with ordinary open-air treatment, with a result of 391 or 64 per cent being apparently cured, 589, most of whom were treated outside of sanatoria, were treated with tuberculin, with a result of 496 or 84.2 per cent being apparently cured. This shows 20.2 per cent more apparent cures with tuberculin than without.

Another test of the value of tuberculin is the permanency of results. It is generally accepted that cases treated by it show less tendency to relapse. Although the comparative results of very few observers have been recorded, yet the general experience is in accord with that of Trudeau⁸ and Turban.⁹ In harmony with this is the observation of Bulloch³ on the opsonic condition of patients who have been treated for tuberculosis. He examined the blood of 14 well-to-do patients who had undergone sanatorium treatment with so called satisfactory results. In every case but one the opsonic index was low. In at least one which was called a perfect cure the disease had relapsed within a year. This also is in harmony with the experience of Spengler. He says "a patient whose agglutinating power is low stands much greater risk of relapse than one whose agglutinating power is high."

Another clinical proof of the value of tuberculin is its action on local visible tuberculosis as we find it in the larynx. Most observers are of the opinion that tubercular laryngitis is almost absolutely fatal. The prognosis is not justifiable if the disease is treated in the proper way. No remedy offers so much hope in these cases as tuberculin. The dosage can be absolutely controlled, and with patience and perseverance a cure can be obtained in a large percentage of cases, even after ulceration has occurred, although the lesser infiltrations are easier to treat and offer better chances of cure. In a report¹⁰ of 15 cases made by me the lesions healed so that there was no further reaction to tuberculin in eleven instances. These results were not obtained quickly. Treatment extended over several months, and in one or two instances many months. The key is patience and care. In a recent visit to many of the world's sanatoria I found that tubercular laryngitis was considered curable or incurable, as the observer used tuberculin intelligently or unintelligently or not at all.

Further clinical proof comes from those who are using tuberculin in treating pulmonary tuberculosis. Moeller's¹¹ statistics show a much larger percentage of cure where tuberculin is used, in fact, the reports from men who are using tuberculin intelligently can not be duplicated by the ordinary method. Some men who are not thoroughly committed to the use of tuberculin employ it in cases which do not improve satisfactorily under ordinary methods. What greater compliment could be paid to this remedy? If it is of such great value in this class of cases would it not be reasonable to suppose that it might also help these same men in some of their easier cases?

Recent reports from Wright⁷ and Bulloch³ show that tuberculin can be used to advantage also in other forms of tuberculosis, such as ulcerations of the subcutaneous

6 Ueber die diagnostische und therapeutische Verwendung des Tuberculins. Zeit. f. Tuberkulose und Heilstaettenwesen 1902 279

tissue and bone, invasion of the lymph glands and infections of the genito-urinary system Wright's results in these usually intractable cases are so good that he says:

In view of the very favorable and what is almost more important, uniformly successful results which can, as will have appeared, be obtained even in the most intractable cases of localized tubercular infection by the therapeutic inoculation of tuberculin carried out under the safeguards explained above, and in view of the fact that not less favorable results can be obtained in connection with the treatment of other localized infections by the aid of the corresponding bacterial vaccines I do not hesitate to contend that we have, in the power of raising the antibacterial power of the blood with respect to any invading microbe, out of all comparison the most valuable asset in medicine. I would, in view of this new asset in medicine, fain induce the surgeon to abate some thing from his conviction that extirpation and the application of antiseptics offer in connection with bacterial infection the only possible means of cure. I would have the surgeon resort to extirpation only when the physician tells him that all other means have been exhausted and I would have the physician assume everywhere the rôle of an immunisator, and I would have him defer handing his patients over to a surgeon before he has tried in every case of localized bacterial infection which is unassociated with immediate risk to life the therapeutic inoculation of the appropriate bacterial vaccine.

With this mass of evidence before us we must admit that tuberculin therapy is in accord with the modern theories of immunity, that theoretically tuberculin is capable of increasing the natural defenses of the organism when given in the proper doses at proper intervals, and that clinical experience in its administration warrants a more general use of it in combating tubercular infection.

CONSERVATIVE SURGERY OF ARMS AND LEGS

JOHN LGERTON CANNADAY, M.D.
Surgeon in Charge Sheltering Arms Hospital.
HANSFORD, W. VA.

The simplest way to treat a badly injured limb is by amputation, but the simple and direct method if it involves too much sacrifice may not always be best for the patient. In certain cases amputation is slightly safer as the attempt to save the limb may be attended with some danger to the patient, while amputation shortens treatment and conservative treatment is tedious and may extend over many months. What patient will not willingly accept a small chance of risk to life rather than the certainty of loss of limb? In times of such great national calamity as war when available hospital space is overcrowded, when proper nursing and dressing are at a premium, many limbs must, of necessity, be sacrificed. At such times both more radical and more conservative surgery must often be practiced than would be deemed desirable in times of peace.

Great stress has recently been laid by Reclus and other French surgeons on the value of systematic conservatism in the treatment of injuries of the extremities some of them going so far as to lay down the rule that no primary amputation should be done. They believe that bleeding points should be ligated, the injured parts irrigated, dressings applied, the general condition of the patient looked after and amputation, if needed, done later when the patient has recovered from primary shock and has accumulated strength with which to combat the dangers of anesthetic and operation. Whenever the circulation of a part distal to the injury is at all fair, there is surely considerable reason for believing that

the limb can be saved. The brilliant work of Carrell and Guthrie in the anastomosing of blood vessels gives promise of something better in the future than has been known in the past for limbs whose main vessels have been divided. The restoration of continuity of tendon and nerve has given most signal functional results in many cases. Extensive laceration of the soft tissues combined with comminuted or other serious fractures constitute a most serious condition and one that will tax the care, the ingenuity and the skill of the surgeon in his attempt to restore anything like a normal condition. The young and healthy individuals will have chances for a restoration of the circulation by the collateral vessels far in excess of the older patient whose circulatory capabilities are on the retrograde. Both the radial and ulnar arteries of the forearm may be severed and yet the circulation be sufficient to save the limb, the femoral artery has been severed and yet the collateral vessels maintained the life of the member. In all accident cases I try to give the patient the benefit of the doubt and make an earnest effort to save the limb, though it not infrequently happens that I have to resort to amputation later. By carefully watching the patient and by the exercise of surgical judgment but little risk to life is assumed by the waiting. Prior to 1877 amputation after compound fracture was the universal rule. Volkmann was the first to secure satisfactory results by other means.

The application of a tourniquet often seriously impairs the vitality of the part, especially so if the constrictor remains in position for any considerable length of time. It is an easy matter to pick up and ligate most bleeding points. A compress held in place by a bandage will control most cases of bleeding. When possible to avoid it the tourniquet should not be used, as the deprivation of blood supply to the distal part entailed by its use exercises a most malign influence on the tissues. The skin may be almost entirely stripped from a limb and yet the chances for restoration be excellent because the blood vessels are uninjured. No matter how large the defect the covering can be restored by skin grafting. It is always best to delay operation until preparations can be made to do the work by a carefully planned and perfected technic. Two or three days' waiting can hardly do harm provided the limb is properly looked after. Many advantages may be obtained by this delay. The patient has ample time to recover from the primary shock and we can tell almost to a certainty whether or not amputation is required.

Do not probe or disturb the interior of the wound before applying first-aid dressing. If this does not control the bleeding apply tourniquet and blanket splint and get the patient to the operating room. The ordinary methods of cleansing pursued are prone to carry much new infective material into the wound. Scrub from, not toward the wound be careful not to allow soap water or other solutions to run into the wound while the limb is being cleansed. Turpentine gasoline benzoin or soap and water followed by alcohol or ether are all effective and their varying use is only a matter of choice. Lastly I apply to the limb 0.5 per cent. iodine solution. I irrigate the wound thoroughly with hot normal salt solution.

If the circulation is good and the condition of the patient warrants it the fractured ends of the bones are united by suture. 30 day chromicized catgut of large size No. 3 being preferred. If wire is used it should be removed after it has served its purpose for the reason that any foreign body left in the tissues, of any

acts as an irritant. Bronze wire is the best, having great tensile strength, iron wire is fair, but silver wire is too brittle to be of service. Severed tendons are sutured, drainage provided for and splints applied. On the other hand, if the vitality of the part is at all endangered there should be just as little interference as possible, useless manipulation may cause much injury to the soft tissues by the cutting done by the sharp fractured ends of the bone. Drainage should be provided, the wound irrigated and the bones held in place by traction or splints or both. Tendons, nerves and bones are better sutured some time later after the circulation of the part has been restored in a measure.

When the fracture is comminuted or oblique, simple wrapping is probably one of the most effective methods of holding the fragments in proper position. Plating is an excellent method of treating some varieties of fracture. All detached bone fragments should be removed, as they will otherwise act as foreign bodies and promote suppuration. Whenever possible the periosteum should be preserved so that regeneration of bone may take place. The wound should be carefully searched for bits of foreign material, and one should see that no soft tissues are interposed between the ends of the bones. When there has been much dirt contamination it is well to give an immunizing dose of tetanus antitoxin as a safeguard.

The after-care of these cases is a great tax on the technical skill and ingenuity of the surgeon. Splints and other appliances for immobilization are too numerous to mention or discuss, a sad commentary on their unsatisfactoriness. The problem of immobilization requires much ingenuity, since no treatise, however complete, can give directions that will cover every contingency that may arise. The varied requirements are practically innumerable. Prevention of motion with fair approximation and apposition of the bone ends must be secured if possible. Frequent changing of the splint in compound fractures has its serious disadvantages and should be overcome if possible. Where there is much mobility an excessive amount of callus will form and may include and press on some important nerve trunk. A fenestrated plaster dressing suits many of these cases and it can be protected from the wound discharges by some of the numerous methods in vogue. A few of these cases, those that are strictly clean and can be kept so, are better off without drainage. Most are infected either by the accident or the treatment, as the opportunities are many and the susceptibility great. Men doing referred practice sometimes blame the physician who gave the first aid for the infection. The wound is often infected before the case is seen by a physician, the conditions often being such that infection is unavoidable, being carried in at the time of the accident from the skin or clothing or from the traumatic agent.

Most of these cases need drainage and gauze strips are usually effective except for hemostatic purposes. Rubber tubing (split or fenestrated) is not only satisfactory as drainage, but is a great convenience when we wish to irrigate the wound. These drains should be placed, whenever possible, so as to get the assistance of gravity. Infected wounds should have ample provision for drainage and irrigation. When there has been extensive laceration of the skin and muscles it is best not to attempt to close the wound completely. There is great liability to suppuration because of the lowered resistance of the traumatized tissues and by reason of the excellent culture media furnished by the extravasated blood and serum and the frequency of initial infection.

I have discontinued the use of peroxid of hydrogen and have never used a bichlorid of mercury solution in the irrigation of wounds. I am satisfied that both promote rather than decrease wound secretion. Warm normal salt solution is a good mechanical cleanser and is non-irritating to the tissues. A weak solution of iodine is possessed of a maximum bactericidal power combined with a minimum toxic and irritant effect. It not only has a destructive effect on pus germs, but to a great extent will seal the ends of the lymphatic and blood vessels against the absorption of septic material.

The fractured ends of the bone may give trouble by necrosis, in which case the necrosed bone may be removed from time to time without much difficulty. In gangrene without infection amputate at the point of fracture and regulate those of the stump later. In gangrene with infection removal of tissue must be radical and extensive. The after care of many in these cases is tedious and prolonged. Necrosed bone will have to be removed from time to time. There will often be chronic suppuration and the patience of both operator and patient will be severely tried. In cases in which trauma has been severe sloughing will usually be extensive and infection almost certain. Antiseptic solutions should not be used on bone, as they are very destructive to the periosteum.

There are certain disadvantages that may accompany the retention of crippled limbs, such as contractions of tendons and fascia, ankyloses of joints, chronic edema from inclusion of blood vessels in callus or scar-tissue, and disturbances of innervation from pressure on nerve trunks, and the treatment is lengthy and expensive. On the other hand, the expense of an artificial limb is saved, contractions and joint stiffness may be largely prevented and overcome by passive motion. Complete ankylosis has been relieved and the joint made mobile by the plastic interposition of fascia between the bone ends, brilliant results have been achieved in nerve surgery even after the lapse of many years from the time of the accident, and tendons are transplanted or anastomosed with ease. True amputation gives in most cases far quicker results, but who does not prefer the arm or leg God gave to some clumsy device contrived by man?

Trauma of joints is often followed by infection. Open treatment by irrigation and packing with iodoform gives good functional results though ankylosis is apt to result. There is an increasing tendency on the part of men who have successful technic to resort more and more to the open treatment of joint injuries and fractures. Bier's method for the production of artificial hyperemia has saved many joints from resection.

With a view to the illustration of the deductions I have made from a study of the subject I have selected the following from a large number of that class of cases, all were notably bad and looked to be fit subjects for amputation.

CASE 1.—D. M., male, aged 22, was referred to me by Dr C. N. Watts, Dothan, W. Va.

History—The man had been shot in the left leg at about the junction of the upper and middle thirds by a Winchester rifle, the ball struck the tibia squarely and produced a billv comminuted fracture. An occlusive dressing with splints was applied and the man kept in his shanty in a railroad camp with the hope that healing would take place. After six weeks of this, suppuration not only of the wound but of the entire leg below the knee had become so general that amputation was considered to be the only means of saving the man's life. At the time the patient came to the hospital he had severe chills, fever and sweats, but I decided to make an attempt to save the leg.

Operation—Under general ether anesthesia the wound was opened, cleansed and several fragments of dead bone removed, four long pus cavities were opened freely, irrigated and drained. These cavities lay in general in the direction of the muscle planes and were connected by sinuses with the original wound. One of them extended some distance above the knee joint into the thigh. Neither the ankle nor knee joints were involved. Under frequent dressings and irrigations some improvement of the leg was manifested, but during the next three months the patient had to be twice anesthetized and new sinuses opened.

Result—At the end of the tenth week after admission to the hospital, the sixteenth week after the receipt of the injury, there was bony union and the patient was put on crutches. In a month he was walking in a limping manner, but the original bullet wound had not yet closed. The leg was painful when much used. Two subsequent operations had to be done for the removal of carious bone. These cavities finally filled and at the end of the tenth month of hospital residence he left, well, with a straight, sound leg, capable of earning his own living and not likely to become a public charge.

CASE 2—D A P, male, was referred by Dr J R. Pharr, Dunloop, W Va.

History—This man had received the full load of a shotgun at short range in the region of the great trochanter on the left side, a large part of the load entering below that point, producing a comminuted fracture of the femur. The shaft of the femur was split by an oblique fracture eight inches long. The outer portion of the trochanter was shattered and the neck of the femur split in half, the separation extending inward as far as the head of the bone. The injuries to the soft structures were most extensive, the flesh being badly lacerated and torn. Shotgun wadding, bits of clothing and fragments of bone were most plentiful in this wound.

Operation—My first thought was to do a hip joint amputation, but I decided to try more conservative treatment. Considerable time was spent in suturing the bones into some semblance of their former shape. The wound was put in as good condition as possible, iodoform gauze was plentifully packed into the gaping cavity and a long well padded side splint applied. Great care was taken to prevent wound suppuration. Union was good, the injury to the muscles filled by granulation, and the patient left the hospital at the end of the ninth week, well.

CASE 3—F B, male aged 21, a saw mill employe.

History—Patient fell so that his left arm came in contact with a rapidly revolving circular saw. Two and one half inches below the elbow the forearm was more than two thirds sawn in two. The radius was cut entirely in two and the articular end of the ulna was torn completely out of the elbow joint and projected backward past the angle of the elbow for at least two inches. He was brought to the hospital about three hours after being injured and was operated on soon afterward.

Operation—The wound was irrigated with saline solution, the fractured ends of the radius were wired and the elbow luxation was reduced. The wound was closed with the exception of a small drainage opening and the arm immobilized in a right angled splint. Healing was primary and passive motion was begun at the end of the second week. Results were perfect and the man now has a normal arm with no elbow ankylosis whatever.

CASE 4—G H W, Olcott, W Va, was referred to me by Dr W W Tompkins, Charleston, W Va.

History—This man had been severely struck on the left elbow in an accident. The arm was terribly swollen, crepitation in region of the elbow joint could be made out and not much else.

Operation—I made an incision lateral to the joint and found that the component bony parts of the joint had been crushed. I resected the broken end of the ulna, also the articular head of the humerus which was fractured entirely across its diameter. Through and through drainage was maintained for a time. A useful arm capable of a considerable range of motion was the result.

CASE 5—H B was referred to me by Dr S M Stone, Hughes ton, W Va.

History—The patient had a Pott's fracture of the right leg, also a compound fracture of both tibia and fibula about the junction of the upper and middle thirds. The injuries to the soft tissues were extensive, there being large lacerations and ecchymoses.

Treatment—The wound was drained and the bones held in position by splints. A large area of the skin sloughed. Edema of the ankle and foot was severe and persistent, and associated with the formation of blebs. The bones finally united, the uncovered areas were repaired by skin grafting, and six months later the patient possessed a fairly useful limb.

CASE 6—C H, white, adult male, victim of a mine accident, referred by Dr J F Bowles, Ward, W Va, had a compound fracture of both bones of the leg midway between knee and ankle, with extensive lacerations of skin and muscles, the lower end of the tibia was projecting from the wound.

Treatment—The wound of four or five hours' standing was irrigated and the displaced bones reduced. Splints were applied. Despite the use of splints and extension it was impossible to keep the bone ends in apposition. A week later the bones were united by suture and rubber tube drainage through the leg was established. There was considerable sloughing of the soft structures and an area of four inches of the anterior surface of the tibia was exposed. The bone surfaces were rapidly covered by granulations until only an inch of the lower fragment was bare. There was considerable infection. The temperature for the first ten days often reached 103 F in the afternoon, later it seldom rose above 100.5 F, and by the end of six weeks it had reached normal. At the beginning of the thirteenth week the patient had a severe chill and his temperature suddenly rose to 104 F. Two days later a beginning abscess was discovered in the calf of the leg and opened. Union was then excellent and the patient was able to bear considerable weight on the leg when walking. Thirteen weeks after the original injury a piece of necrosed bone 3 inches long by 1 1/4 inches wide at the upper end and 1/2 inch wide at the lower end was removed from the lower fragment of the tibia. The wound is nearly healed and except for a little stiffness in the ankle joint the prospects are good for complete recovery.

CONCLUSIONS

- 1 The conservative treatment of severe injuries to the arms and legs is essentially modern, and we should not do primary amputations (except in case of a limb held by only a few shreds), but wait for shock to pass and for the patient to regain strength.

- 2 We should avoid the use of antiseptic solutions for irrigation and use instead normal salt solution.

- 3 Bones should not be permanently sutured and we must not be in too great a hurry nor attempt too much in the beginning.

- 4 Moist gangrene calls for radical treatment.

- 5 Drainage is usually necessary and the rubber tube is to be preferred.

- 6 Good functional results may be obtained against great apparent odds and a saved limb is preferable to an amputation stump.

Therapeutic Power of Mental Effort—Dr F T Seybert, Council Bluffs, Iowa, states that the therapeutic power of mental remedies is best illustrated in the treatment of functional nervous disorders especially when associated with mental symptoms. A natural susceptibility which is one of the strongest factors in the etiology of these disturbances becomes when judiciously managed a means by which curative action can be aroused—so sure is Nature in her combinations. In neurasthenia above all other diseases there is no prescribed routine of treatment its diverse causes and varied nature would prohibit this. All remedies which have any bearing and all influences are sometimes called for. He who has the clearest insight and the wisest ways and means will be the most successful. Mental occupation is often beneficial and the employment of the mind is a

sugar with a few spoonfuls of the buttermilk until a smooth paste results. All lumps should be completely smoothed out. The balance of the buttermilk is then added. This mixture is now heated to the boiling point (212 F), but must not be boiled or it will curdle, it is also essential that the milk be constantly stirred during the entire process or it will curdle.

If a thermometer is not used, at the first sign of bubbling the milk is removed from the fire and rapidly cooled. It is best now to bottle the food, but in dispensary practice if the patients can not afford enough bottles for the entire day the buttermilk should be placed in a pitcher or jar which has been scalded and placed on ice. Before taking out the milk for each feeding the buttermilk mixture must be carefully stirred, as on standing it separates and the flour falls to the bottom of the vessel. It will be noticed that no water whatever is added to this mixture.

I report the cases of twelve infants, these are all I have fed up to date on buttermilk. I wish also to state that I have not selected cases which would be expected to do well, but with the exception of two cases of acute enteritis, which were put on buttermilk at their first visit, in every case regular milk mixtures were carefully tried but without success, before the infants were given buttermilk. Five of these cases were in the baby ward of the Philadelphia Hospital and seven in the dispensary of the Children's Hospital of Philadelphia.

First I will report the cases of five babies in the Infant Asylum.

CASE 1.—M M was admitted to the Philadelphia Hospital when 3 weeks old. For a few weeks the infant was breast fed, but as it lost in weight, it was put on a milk mixture alternating with the breast. The baby gained only eleven ounces in three and a half months. By this time the child had a well developed case of marasmus, the four months' old infant weighing only 8 pounds 11 ounces, and its evacuations showed undigested food. It was now put on the buttermilk mixture and in three days the stools were normal and the infant had gained ten ounces, in ten days it gained 1½ pounds, or an average of 2½ ounces a day. In the three and a half weeks during which it took the buttermilk it gained 39 ounces, or 11 ounces a week.

Before taking the buttermilk this baby gained only 11 ounces in 3½ months, but after taking it gained that amount each week. This is an unusual result in a case of infantile atrophy confined in a hospital from 3 weeks of age to the age of 4 months.

CASE 2.—C S was admitted to the Philadelphia Hospital when 9 hours old. This new born baby was fed on a regular milk mixture for four weeks, in which time it had lost 14 ounces and had developed a severe gastroenteritis, vomiting after each feeding and showing undigested food in the stools, together with a large quantity of mucus. When one month old it weighed 7 pounds 7 ounces, and was put on the buttermilk mixture 1 ounce and water 1 ounce. In three days, as vomiting ceased and the stools showed that the food was properly digested the baby was put on 2 ounces of the buttermilk mixture undiluted. As it did not digest this, the stools containing curds, it was put back on one-half buttermilk and one-half water and again improved. In three weeks after taking the buttermilk the infant had gained 9 ounces, or 3 ounces a week and the stools were much improved.

To recapitulate, a new-born baby, in an institution, artificially fed on a modified milk mixture, developed a gastroenteritis and lost rapidly in weight until given buttermilk, when improvement in digestion occurred and slight gain in weight. But for the mistake of putting this infant on buttermilk undiluted I believe the improvement would have been much more rapid.

If fresh buttermilk can not be obtained it may easily be made at the patient's home. The following is the method used at the Philadelphia Hospital. A quart of fresh milk is poured into a sterile pitcher and a sterile cloth tied over the top of the pitcher to prevent the entrance of dust. This milk is allowed to stand for twenty-four hours in the room, at ordinary room temperature (65 to 70 F), and at the end of that time all the cream is skimmed off. This sour milk is placed in a small glass churn of one quart capacity and churned for fifteen minutes. It is then removed from the churn and placed on ice until the nurse is ready to prepare the buttermilk mixture. I have examined buttermilk made in this way and found it to contain 1 per cent of fat. Buttermilk should be used within twenty-four hours after being made.

Plain buttermilk was not given, but the babies I report were fed routinely on a mixture of wheat flour, cane sugar and buttermilk in the following proportions: Buttermilk 1 quart, wheat flour, 3¾ teaspoonfuls, granulated sugar, 15 teaspoonfuls. A farina boiler, that is a double boiler, is the best receptacle in which to prepare the food. First, carefully mix the flour and

CASE 3—F T, a foundling with infantile atrophy, had been in the baby ward of the Philadelphia Hospital for three and one-half months when it came under my care. It was then 5 months old, weighed 7 pounds 8 ounces, and was taking 5 ounces of a 3-6-1 mixture. Since it had been in the hospital it had lost 1 pound 3 ounces. At my first visit I changed its formula to a 3-6-1-25 mixture, 6 ounces every third hour. In the next two weeks the child gained 11 ounces, but at the end of this time it began vomiting after each feeding. The percentage of fat was cut down, and the child put on a 2-6-1-5.

1 Throughout this paper when the percentages of different ingredients in a milk mixture are given it must be understood that fat, sugar and proteid are arranged in the order here stated. For example, a 3-6-1 mixture refers to 3 per cent. of fat, 6 per cent. of sugar and 1 per cent. of proteid.

mixture, with the addition of sodium citrate (one grain to each ounce of milk and cream in the mixture) Ten days later the baby vomited less frequently and the formula was changed to a 2 6 1 75, with sodium citrate Two days after this the baby vomited large curds after each feeding, and the stools became yellowish green with curds The baby had lost 6 ounces in the three days The milk mixture was discontinued, and barley water was given for twenty four hours, followed by whey for forty eight hours, but as there was no improvement in three days, infant was put on the buttermilk mixture, 4 ounces every three hours The next day there were no more curds and the stools were normal He took the buttermilk well, and only vomited twice. The quantity was then increased to 5 ounces every three hours Twelve days after buttermilk was started, vomiting had entirely stopped The stools were normal, and baby had gained 18 ounces, or an average of $1\frac{1}{2}$ ounces a day since taking the buttermilk.

It would certainly be hard to find a more severe test to apply to any food than the test buttermilk was subjected to in this case In brief, a 7-weeks-old foundling remaining in an asylum $3\frac{1}{2}$ months developed infantile atrophy with gastroenteritis Was put on buttermilk and a rapid recovery followed

CASE 4—O W W, born in the maternity of the Philadelphia Hospital, and was breast fed until transferred to the baby ward at the age of 6 weeks, weighing 7 pounds 2 ounces It was fed on barley water 1 ounce and whey 1 ounce, with one grain of sodium citrate, but the stools were green with curds and mucus and the baby losing slightly in weight Put on buttermilk 3 ounces every two hours, in three days the infant gained 3 ounces, the stools were dark brown, with a few small curds, having noticeably improved By the end of the first week baby had gained 10 ounces and stools were yellow and well digested But on the eighth day child began vomiting and continued vomiting after every feeding The infant became very much worse, and stools became green with curds Put on one half buttermilk mixture and one half water, but did not improve, losing rapidly in weight Vomiting persisted in spite of daily lavage Buttermilk was discontinued and patient put on plain whey plus sodium citrate, but it lost even more rapidly than while taking buttermilk

This baby was a typical case of the atrophic type seen in foundling asylums, who almost always develop acute gastroenteritis and die The child was born in the institution and weighed at birth 7 pounds 4 ounces Two months later, before given buttermilk, he weighed an ounce less than at birth Buttermilk was given for three weeks, the first week the baby gained 12 ounces and in the second and third weeks together he lost 8 ounces After the child was taken off buttermilk it went rapidly down hill

CASE 5—P B B, aged 3 months when admitted to the Philadelphia Hospital Four weeks after admission the infant developed an acute enteritis It had been taking a 3 6 1 mixture, but now refused its feedings, up to this time it had gained $2\frac{1}{2}$ ounces a week since admission It was now put on buttermilk, and in twenty four hours the stools were greatly improved, although previously they had been full of curds, they were now well digested The baby took the buttermilk well and retained all of each feeding In one week, beside having normal stools, the baby gained 1 pound 2 ounces At the end of the second week, 2 drams of 10 per cent cream were added to each feeding (approximately 1 per cent of fat) A few days after the cream was added the baby began to vomit and the stools showed undigested food, containing curds and mucus The child also lost 2 ounces in weight The cream was discontinued and the baby ceased vomiting and the stools improved Again in three days the buttermilk was increased to 5 ounces and 1 dram of cream (16 per cent) added Four days after this the stools were perfectly normal, yellow, and showed good digestion Taking and retaining its feedings the child gained over 3 pounds in four weeks, or an average of over 12 ounces a week.

It should be remembered that this infant could not digest 1 per cent. of proteid in a regular milk mixture, but was able to digest the 2 per cent to 3 per cent of proteid in the buttermilk I consider this an unusual result, especially when we remember this baby had been in an infant asylum for two months

The reports of these five cases unfortunately cover only a short interval of time. My service expiring, I was unable to treat them for a longer time. The following are dispensary cases.

CASE 6—L M, aged 7 months, was brought to the dispensary Jan 14, 1907, weighing 8 pounds 13 ounces. This was a case of infantile atrophy. The child had been fed on the breast, alternating with the bottle ($\frac{3}{4}$ milk, $\frac{1}{4}$ water). Baby had not thrived since birth, always had colic with constipation. Mother gave her infant magnesia daily to relieve the constipation. Baby vomited frequently, both breast and bottle milk, while the stools contained curds. The infant was put on a milk mixture, but in three days, as it continued to lose in weight, and the bowels had not improved, it was put on the buttermilk mixture, 4 ounces every two hours, and given the breast twice during the night. Two days later the infant had gained 6 ounces. The stools were still green and offensive, but contained no mucus or curds. Baby had not vomited, so the buttermilk was increased to 5 ounces every two and one-half hours. Two weeks after taking buttermilk the child was perfectly well. Its stools were normal, and it was taking 7 ounces of the buttermilk every three hours. It had gained 36 ounces in the two weeks, or over $2\frac{1}{2}$ ounces a day.

To repeat. An infant, 7 months old, weighing 8 pounds 13 ounces, suffering from infantile atrophy and with a chronic gastroenteritis, was put on buttermilk. The stools rapidly became normal, the child gaining $2\frac{1}{2}$ ounces a day. This infant retained and digested buttermilk, but it could not digest or retain its mother's milk or a regular milk mixture.

CASE 7—O J, aged 15 months, was brought to the dispensary Nov 7, 1906, suffering from chronic intestinal indigestion. This infant had been on condensed milk in the proportion of $3\frac{1}{2}$ drams to a teaspoonful of water. About four weeks before coming to the dispensary the baby had two weak spells, probably convulsions. From that time on she was feverish at night, and the bowels continued loose, with curds in the stools. To be brief, the infant was brought regularly to the dispensary for three weeks before I put it on buttermilk, and during this time I was unable to feed it successfully. This 15 months' old infant could not even digest 175 per cent of proteid in a skimmed milk mixture. I have never seen a child pass such large tough tenacious curds as this infant did. The stools were also green, contained mucus, and were very offensive. In twenty-four hours after taking the buttermilk mixture the character of the stools was entirely changed. They showed good digestion and were absolutely free from curds. The infant's colic, which before taking buttermilk had been very severe, ceased. In six days the baby gained 21 ounces, or $3\frac{1}{2}$ ounces a day and the stools were normal. Then the mother neglected to bring the child for three weeks, and as it lost 7 ounces in weight, one dram of 10 per cent cream was added to each feeding of 8 ounces of the buttermilk mixture (approximately $\frac{1}{4}$ per cent of fat). Even this small quantity of cream had to be discontinued in two days, as the bowels became loose and the stools watery. The child tired of buttermilk in three weeks and would take only two or three ounces at a feeding so broth and white of egg were added to its diet, and a few days later, scraped meat and orange juice. The baby's bowel movements continued to show good digestion, but averaged four or five a day and still contained some mucus.

For months this child had eaten dirt and had been discovered eating coal dirt and ashes out of the coal-scuttle. It could not be expected that this child now $1\frac{1}{2}$ years old, would continue gaining on simply buttermilk, but as a temporary food in this case its effect was most striking, the improvement, as soon as it was put on buttermilk, was really wonderful.

CASE 8—J C, aged 5 months, was brought to the dispensary Dec 26, 1906, with acute intestinal indigestion and rachitis. The infant had been fed since birth on condensed milk ($\frac{1}{2}$ teaspoonful of condensed milk in 4 ounces of water). Its mother said the baby had never been sick until four days

previously, when diarrhea set in with much tenesmus. The stools were green, offensive, and contained a good deal of mucus. The baby was put at once on the buttermilk mixture, 4 ounces every two and one-half hours, and in twenty-four hours was much better, the diarrhea was less and the stools were becoming normal. In three days the child gained 12 ounces, and the stools were normal, although four a day. The infant was not brought to the dispensary for eighteen days, and in that time it gained 27 ounces. The baby's general condition was excellent, two normal evacuations daily and no vomiting. It was put on 5 ounces of buttermilk and 1 dram of 10 per cent cream every three hours. After taking the buttermilk this baby gained 41 ounces in five weeks, or 8 ounces a week.

This infant, having acquired rickets from being fed on condensed milk for five months, developed an acute enteritis but without putting the child on barley water for 24 hours, as I generally do in similar cases. I placed this baby directly on the buttermilk mixture and it began immediately to improve. This case illustrates the value of buttermilk in acute intestinal disorders in infancy.

CASE 9—E A, aged 5 months, was brought to the dispensary Dec 26, 1906, weighing $11\frac{1}{4}$ pounds. This was an atrophic infant with a moderate degree of rachitis. The patient had been breast fed until 3 months' old, when it was put on condensed milk, which failed to nourish it, and then on a modified milk, approximately a 47.125 mixture. For five days before coming to the dispensary the infant had been vomiting after each feeding. Bowels moved three or four times a day and there were always curds in the stools, there was much colic and flatulence. After taking barley water for twenty-four hours the child was put on a 36-1 mixture alternating with the breast. One week later, as the mother had plenty of breast milk, the infant was put on breast milk exclusively. In one week on breast milk it lost 1 pound 2 ounces. In the two weeks it had been coming to the dispensary it had lost 2 pounds. It was now put on the buttermilk mixture, alternating with the breast. At first it gained rapidly but colic continued and in a week it lost some that it had gained. The breast was then discontinued entirely except during the night, and the child gained once more. A week later, it again lost in weight and developed all the symptoms of hereditary syphilis. It was placed on an anti-syphilitic treatment and then gained in weight. In the three weeks this atrophic rachitic syphilitic infant gained 2 pounds, or 10 ounces a week.

This baby could not digest a 36-1 mixture or its mother's milk, and lost rapidly while taking them. It improved when buttermilk was given alternating with the breast but it improved still more when fed on buttermilk exclusively.

CASE 10—J M, aged 14 months, was brought to the dispensary Dec 11, 1906, with an enterocolitis. The infant had been passing blood in its stools for three weeks and having bowel movements seven to eight times daily. The stools were green and besides blood, contained mucus and curds. The child had been fed on condensed milk $1\frac{1}{2}$ ounces to 6 ounces of water. This infant was put immediately on the buttermilk mixture, 6 ounces every three hours, without the usual twenty-four hours on barley water. In forty-eight hours the stools were still green but contained no curds nor blood. The infant at this visit weighed $18\frac{1}{2}$ pounds. Three days later the child developed an acute bronchitis and its bowels moved four or five times a day. The stools containing mucus. At the end of the first week the infant had lost one ounce. It was then ordered 8 ounces of buttermilk and 2 drams of 10 per cent cream. At the end of the second week the baby had gained 8 ounces but stools contained some curds and were green and offensive. At the end of the third week the patient had gained 13 ounces more and its stools showed good digestion. Six weeks after taking the buttermilk mixture the stools were perfectly normal and the infant's weight was 21 pounds 5 ounces, or a gain of 42 ounces, 7 ounces a week.

Remember this child had had for 3 weeks an intense enterocolitis which was increasing in severity and at the first visit it was placed immediately on buttermilk. I did this in order to put the buttermilk to a very severe test, and in 24 hours there was a marked improvement in the character of the stools.

CASE 11—C C, a 3 months' old baby, was brought to the dispensary Dec. 17, 1906, with infantile atrophy. It was breast fed until 6 weeks old, after which time it was fed on a predigested milk mixture, approximately a 1561 mixture. The baby since being fed on this mixture had always been constipated, until three days before coming to the dispensary, when its bowels became loose, the stools showing undigested food and there was much flatulence and colic. The child weighed when first seen, 8½ pounds, but the mother said it used to weigh 9½ pounds. The infant was given a dose of oil and put on albumin water for twenty four hours, and then on a 36075 mixture. In one week the patient lost 14 ounces, and the stools were loose, green, contained curds, and were offensive. Baby vomited after each feeding. It was then put on buttermilk and in three days it gained 12 ounces. The baby's general condition improved greatly and its bowel movements showed good digestion, but it still vomited a little. In one week the child gained 1 pound 4 ounces. Four days later baby had lost 4 ounces because the mother had been unable on two days to obtain buttermilk, so she put the baby on the milk mixture she had given it before coming to the dispensary. The infant was only brought a couple of times after this, it was gaining slowly, but as the mother said she was unable to obtain buttermilk every day, she returned to her home in the central part of Pennsylvania, where she could get plenty of fresh buttermilk.

I do not consider it fair to attribute the slow gain during the last two weeks this case was under treatment to buttermilk, as it was not given every day. Nevertheless, the average gain in weight for the three weeks while coming to the dispensary was 8 ounces a week.

This baby could not digest 75 per cent of calcium casein, the proteid as it occurred in the milk mixture that the child was taking before it was put on buttermilk, but at once it fully digested the 2 per cent to 3 per cent of casein lactate in the buttermilk mixture.

CASE 12—M K., a 3 months' old rachitic infant, who had been fed since birth on too strong a milk mixture, and in consequence had indigestion. It was put on a weaker mixture, but indigestion continued and the infant failed to gain in weight losing 1 ounce. It was now put on the buttermilk mixture and the stools changed immediately, becoming smooth, yellow and well digested. The child gained 8 ounces the first week on buttermilk, and continued gaining for two months. Up to the date of writing it had gained 3 pounds, or in other words 6 ounces a week, its weight then being 14¼ pounds.

This case is an example of an infant developing rickets and losing weight on too strong milk mixture, with fat and proteid indigestion. Improving immediately on buttermilk, gaining constantly and rapidly.

In order to give this mixture of buttermilk, cane sugar and wheat flour a fair trial, I purposely did not modify it, but used the whole buttermilk in every case, with two exceptions. There were two cases in which I diluted the buttermilk one-half with water. These were the only patients that did not perfectly digest the proteid of the buttermilk. Both were asylum infants, one was the 1-month-old baby, and the other the case of marasmus that was not successfully fed on buttermilk or on anything else.

The one way I did modify it, which is essential if the child is to be kept on buttermilk for any length of time, was by the addition of fat in the form of cream. The cream was added just as soon as it was thought the infant needed fat in its diet and could digest it. At first one-quarter of 1 per cent. of fat was added, and if

this was taken well the amount of fat was increased one-half of 1 per cent at a time as rapidly as possible. For instance, if the child was taking 4 ounces of buttermilk, 2 drams of 16 per cent cream was added to each feeding.

SUMMARY

The twelve infants reported varied in age from 1 month to 15 months old. The average gain in weight of the five babies treated in the Philadelphia Hospital was 7½ ounces a week. The average gain in weight of the seven babies treated at the dispensary was 8¾ ounces a week.

The average gain in weight of the entire twelve infants fed on buttermilk was 8 ounces a week.

This gain in weight is particularly of interest for the reason that every one of these twelve cases were seriously ill at the time they were put on buttermilk. I would call special attention to the five babies in an infant asylum, whose average gain was 7½ ounces a week.

CONCLUSIONS

One advantage of buttermilk in dispensary practice is its inexpensiveness, costing in Philadelphia only 5 cents a quart.

I believe fresh buttermilk a most excellent temporary food for infants suffering from intestinal indigestion, enteritis and marasmus.

I have observed no unpleasant effects from the administration of fresh buttermilk, infants almost invariably take it well.

A few of these infants, when first put on buttermilk, vomited slightly, but in every case this ceased in a day or two, with one exception (Case 4).

Finally, the point I wish to emphasize from my brief experience is, whatever success has attended the use of buttermilk, is not so much due to the absence of fat as to the great ease with which the proteid of buttermilk is digested. I have had the opportunity to observe this in almost every one of my cases. Several who were unable to digest 0.75 per cent. of calcium casein digested perfectly the 2 per cent to 3 per cent of casein lactate in the buttermilk.

1805 Spruce Street

THE PROBLEMS OF CAR SANITATION *

THOMAS R. CROWDER, M.D.
CHICAGO

The railway had long ago reached such a stage of activity in America that its sanitary problems became of importance. It was not until very recent years, however, that these problems were adequately or at all generally discussed. The rapid development of the means of travel gave us a new set of sanitary questions. These have been in part answered in the papers by Bracken,¹ Hurty,² Conn,³ Dudley,⁴ Trask,⁵ Rosenau⁶ and others.

* Read at the annual meeting of the American Public Health Association, Mexico City, December, 1906.

1 (a) Sanitation and Its Bearing on Certain Railway Problems, The Railway Surgeon, September, 1903. (b) Infection in Transportation, Am. Med. Aug. 12, 1905. (c) A Few Points Relating to Car Sanitation, Rep. of Am. Pub. Health Assn., 1905, xxxi.

5 The Dangers of Unrestricted Traveling of Consumptives, Jour. of Assn. of Mil. Surg., 1905.

6 Internat. Jour. of Surg., May, 1902, p. 157.

That the problems presented have not yet been solved in all their relations, however, is amply proven by the great diversity of opinion still held by sanitary experts. Further investigation is needed. It is desirable to know many facts difficult of determination. But in the working out of new sanitary problems frequent orientation is necessary in order to keep them in their right relations, to apply the general principles of sanitary science, and to prevent confusion of the major and minor questions at issue. I wish to make a brief inquiry into the dangers which railway travel may hold out to the public health and to measure the influence of car hygiene in averting these dangers.

This inquiry may be directed under three general headings. First, the danger arising from the mechanical accidents, second, the danger of contracting infectious diseases, third, the danger incident to a group of miscellaneous influences, such as the rapid and variable motion, faulty ventilation, heating and lighting of cars, and the breathing of dust, smoke and engine gases.

DANGER FROM MECHANICAL ACCIDENTS

First.—Though the first of these items—the danger from mechanical accidents—is, in its ultimate analysis, the most important, and in the broadest sense a sanitary problem, we may, for the present purpose, leave it out of consideration. In the nature of things the professional sanitarian has little to do with the measures taken to prevent such accidents. They are the special concern of the railway management, and require neither the knowledge nor the training of the physician to properly interpret and understand. The economic consideration which they involve may be trusted almost alone to work out their remedy.

DANGER FROM INFECTIOUS DISEASE.

Second.—The liability of a passenger to acquire an infectious disease during his period of travel, while a more intangible danger, is one, the protection from which is the sanitarian's special interest, and its correct interpretation requires all his technical training and his knowledge of technical facts. It covers most of the important problems of our sanitation, strictly interpreted.

We may profitably divide our consideration of this phase of the subject also into three parts. 1, The danger of infection through association, that is, by direct contagion, 2, the danger from the use in common of the facilities for comfort and convenience, 3, the danger from the infected car.

1. The association of any considerable number of persons in any confined space renders each one a possible victim of the contraction of a contagious disease. This holds true in the railway coach in the same degree that it holds true for other public places. It is increased by the railways only to the extent that they facilitate intermingling. That the average danger is in general slight and is not worthy of exerting any deterrent influence on social intercourse or travel seems to be a generally accepted opinion. It is nevertheless probable that such association is responsible for a very large proportion of the ordinary acute infections, and particularly of those affecting the air passages.

It is, of course, desirable that every effort should be made to limit as far as possible the association of the diseased with the healthy in public places. The only obvious way to accomplish this is to deny to the sick the right of mingling with the well. In case of smallpox, scarlet fever, measles, diphtheria and a few other manifestly contagious diseases we do this, depriving the af-

fected individual of his liberty if necessary to insure his isolation. But a host of other infections, which may under certain circumstances become directly communicable, are allowed to associate at will. Consider for instance, influenza, a disease usually prevailing in epidemic form, spreading with such remarkable rapidity as to leave no doubt of its extreme contagiousness. Produced by a bacillus known to have very little resistance to desiccation, sunlight and unfavorable temperatures⁷ to exist in large numbers in the sputum and nasal secretions of the infected, the disease is transmitted directly from man to man, and chiefly, it is supposed, by means of infected droplets expelled in coughing and sneezing. Those afflicted with influenza are very often still well enough to go about their business and their travels and thus be spreaders of the infection. Again, it has long been recognized that mild and atypical cases of various contagious diseases are by no means rare. That scarlet fever may have no eruption, mild sore throat be really diphtheritic, that even smallpox may be mild and unrecognized, are facts which have been well established during the last decade. Indeed, we know that there is a vast number of people with unrecognized contagious disease who go about in apparent health spreading their infection. Furthermore, it is well known that virulent organisms may continue to be produced in the bodies of those infected for weeks or months after recovery from the disease, and that pathogenic organisms are frequently found even in those who have never been sick at all. How, then, is it possible to escape from the dangers incident to association? It is not possible to exclude the infected but only the sick, and whoever is able to go about with the appearance of health will continue to be our fellow traveler.

How far is the railroad able to aid in preventing contagion from this cause by contributing to the desirable segregation of the diseased from the healthy? Dudley^(a) has defined the situation so clearly that I quote in part his words:

"It may be urged that the railroads have no right to expose their healthy passengers to the danger of contracting diseases from others, and that they should exclude from their cars all people affected with communicable diseases."

While it is undoubted that the railroads have a right to exclude, and, for that matter, do exclude, from their cars people known to have contagious diseases, such, for example, as smallpox, it is entirely evident that the exercise of this right depends on correct diagnosis. To refuse transportation to a person or persons because they were suspected by the ticket agent or conductor of having a communicable disease might entail serious consequences.

Railroads are common carriers required to perform certain public duties, prominent among which are the transportation of persons and property. It is not possible to refuse transportation except under certain well defined conditions, and, since neither ticket agents nor conductors are, or can be from the nature of the case, physicians, it is difficult to see how, at least under present legislation, transportation is to be denied even to those who may be affected with communicable diseases. The proper remedy

if any remedy is possible, would seem to be in legislation making it a crime for those afflicted with certain communicable diseases to ask for or to accept transportation from common carriers."

TUBERCULOSIS

One of the most serious diseases travelers are exposed to is tuberculosis. While we must look on this as a disease possible of direct transmission and while its prevalence and destructiveness are appalling, public sentiment, and even the sentiment of the medical profession

⁷ Ricketts. *Infection and Immunity* Chicago 1906 p 215

approves of granting it the right to travel. The railroads can not refuse its victims transportation as dangerous passengers in opposition to the public sentiment which permits them the freedom of all other places, public and private. While I believe it would be well to restrict the freedom of the tuberculous, still, in recognition of the possible benefit that changes of climate may have on the disease, I am not now willing to advocate preventing them from taking advantage of such travel as they are able to undertake in search of health. We are all undoubtedly more or less exposed to this widespread infection at some time in our lives, and the little more or less exposure involved in the healthseeker's travel is probably not of great consequence, the time of association being relatively short and not necessarily close. Much, however, may be done to limit the danger occasioned by the tuberculous whether in cars or elsewhere. Their danger consists in spreading their sputa about them, projecting infected droplets into the faces of others or infecting the things they use, all of which may be avoided or at least so nearly avoided by correct personal habits that the danger practically disappears. Teach the tuberculous that they are dangerous and instruct them in personal hygiene, for so long as they are permitted to associate in freedom with their healthy contemporaries they probably must also be allowed the privilege of traveling in the railway coach. The sanitarium for the tuberculous is a safe place for the well. It is made so by the patients themselves. The railway coach deserves similar protection.

This leads me naturally to speak of the often repeated proposal that special cars should be furnished for the diseased, more especially for the tuberculous. The proposal undoubtedly has great virtue, and I would say that it should be acted on forthwith if there were not what seem to me insurmountable obstacles to carrying it into effect. In the first place, there is the economic consideration. The amount of such travel will not justify furnishing special cars. These people are often—indeed, usually—too poor to pay for the extra expense entailed. Railways are economic institutions and can not be expected to furnish transportation at a loss. The state is not yet sufficiently impressed with the desirability of isolation to be willing to pay the deficit. But of even greater practical importance is the great probability that it would be impossible to get more than a small proportion of tuberculous patients into such special cars. It is not necessarily the bedridden consumptive who affords the greater danger of infecting his associates. Far more important is the patient, either unsuspecting or showing no conclusive signs of the disease to the casual observer, who would still insist on traveling as a healthy individual travels. Of this class of patients there are vastly more going about the world than of those severely sick. Only a law making it a misdemeanor for him not to declare his disease when applying for railway transportation would force him into his proper compartment, and even then, perhaps, a large proportion of them would either avoid or defy the law and take their places in the ordinary coach and sleeping car and escape detection. In its last analysis the question would remain not so much one of the car as of the habits of those who use the car.

By adopting a pessimistic view we may theorize the dangers of free social intercourse into formidable proportions. The most constant optimism can not argue it into an entirely negligible quantity. I have already expressed the opinion that direct contagion is responsible

for most of the contagious diseases, but we must confess that it is a subject which it is difficult to materially alter in any other way than by education in personal hygiene which both the sick and the well should apply or by changing public sentiment on the subject of allowing those sick of certain diseases the freedom of intercourse and travel.

THE CHANCES OF INDIRECT INFECTION

2 What are the possibilities of indirect transmission by reason of the use in common of a car's facilities for comfort and convenience? The answer to this question goes back, in great measure, to the determination of how many travelers are afflicted with transmissible diseases or harbor pathogenic organisms—a subject which has been touched on in the consideration of direct contagion. Statistics are not at hand, and are scarcely possible of compilation, showing the proportion of the infected to the healthy among railway travelers. Yet to determine with any degree of accuracy the possibilities of danger held out by them, either from direct or indirect contagion, it would be necessary to know the proportion of the whole each disease constitutes. I do not mean to imply that knowing this would satisfactorily answer the inquiry. It would rather furnish premises from which we might hope to reason logically on the liability of transmission. It would still be necessary to establish, however, the degree to which various utensils must be contaminated before they could be said to hold out real danger of infecting the user. The contraction of disease by infection is so largely a matter of individual resistance and susceptibility that it is difficult, indeed, to draw sharp lines on its probability. The number of organisms which in one person produces disease may be innocuous to another. We may compare pathogenic bacteria to poisonous drugs and speak of a harmless, toxic and lethal dose. Theoretically I suppose it may happen that the smallest dose—a single organism—might be capable of producing a disease, but phagocytes, opsonins and other protective bodies of the human tissues are generally able to overcome considerable numbers of even the most virulent bacteria, and absolute sterility of the things we use, even freedom from pathogenic organisms, is not necessary in order for the great majority of us to escape infection.

The railway should provide facilities in keeping with the state of sanitary science and the hygienic habits of the people, it can not, however, at all times enforce their proper use, and at any stage of perfection in the facilities provided abuses are liable to occur which must be laid at the door of the public. The providing of sanitary appliances is the railroads' duty, the maintenance of sanitary conditions is largely dependent on the users. Consider the wash basin. It is much maligned, and, to a degree, justly so. It is often left abominably dirty by the user, it is much used as a receptacle for washing the teeth, it is frequently used as a cuspidor. With smooth basins and plenty of water this will entail no very great danger, perhaps—we regularly use contaminated water for bathing purposes and consider it safe—but it is, at least, a disgusting and a dirty habit. It does not arise from the conditions existing in the railway coach, it is brought there by habits formed at home, and it should be corrected at home. There is no place in the car devoted solely and especially to tooth washing, nor is there one in any other place, but there are smooth basins and plenty of water, there are cuspidors and there is a closet adjoining the lavatory. These can easily be made use of to avoid both the danger and the disgust

until some new device is especially provided for tooth washing. People generally neither try nor care to do so at this time. Before we are through with the crusade against spitting they must be taught that it is not sufficient to avoid spitting on the floor or the sidewalk, but that a wash basin is not to be used as a cuspidor and that drinking cups should be held sacred against tooth brushes.

The dangers of indirect infection in railway coaches increase theoretically, and no doubt practically as well, in proportion to the length of time a car is in service on any single trip. The longer the trip the longer the personal association of passengers, the greater their necessity of using toilet and other facilities at hand, and consequently the greater the liability of pollution. Other things being equal, the sleeping car would, therefore be more liable to contamination than the day coach. Its average journey is longer. Other things are not equal, however because of the constant supervision of the sleeping car en route, more care at its cleaning terminal, its average higher class of patrons, and its carrying fewer persons to the car.

It is largely in the power of railway passengers to annul on the one hand the dangers incident to their own intermingling and, on the other whatever measures the railroad may take for their protection. They have the right to demand, nevertheless, that the railroad provide facilities whereby they may carry out to the utmost their own protection. Closets should be well flushed perfectly emptying and capable of easy cleaning. Lavatories should be supplied with abundance of water well drained, trapped to prevent back flow of water and entrance of dust, the surface should be smooth and easily cleansed by rinsing and wiping. If each user would rinse and wipe out a wash basin after using it he would do no more than his hygienic duty and reduce to the vanishing point its liability of conveying infection. Small towels should be supplied in such abundance that each needs to be used but once. While the common hand towel is perhaps practically without danger one should never be obliged to use the common face towel on account of the danger of trachoma and other eye diseases.

The common drinking cup has been much discussed and rigidly criticised of late and orders for abolishing its use entirely have been considered by the surgeon-general of the United States Public Health and Marine-Hospital Service. It would be a sweeping reform, and the effect of such a move on the public humor can not be read in advance. For the present the railroad is obliged to furnish some thing in the way of a drinking cup however and the attempt should be to provide one with the least liability of conveying infection from lip to lip. It should have a perfectly smooth surface, outside and in, preferably made of glass to better accomplish this result and to render immediately visible gross contamination and dirtiness. It is through the medium of the common drinking cup that the closest indirect relations from a hygienic viewpoint are established between passengers and it is here, perhaps, that the greatest danger of the indirect transmission of disease arises. There is considerable experimental evidence of cup contamination. A. Moeller³ of Berlin has recently found tubercle bacilli influenza bacilli staphylococci and streptococci on the edges and in the residue remaining in communion cups. Kinyoun⁴ found pneumococ-

cus streptococcus staphylococcus aureus and diphtheria bacillus once each in twenty-one drinking cups from sleeping cars. Probably cups in constant or oft-repeated use are very generally infected, since mouths are always so and people generally are careless drinkers. For the most part they contain harmless bacteria (Kinyoun found but one of the organisms isolated to be really pathogenic, the diphtheria bacillus while the pneumococcus was very slightly so), and the same number of organisms found in the wash basin would no doubt be entirely harmless, but the drinking glass comes a little too close for comfortable suspicion. Its contents gain direct entrance to the body and traverse the whole gastrointestinal tract with its vast extent of absorbing surface where some point of entrance for organisms may be found. Obviously the danger of transmission from this source is greatest in those diseases where there are lesions in the mouth as syphilis actinomycosis aphthae and tonsillitis and quite as obviously the simplest way to avoid it is for each person to carry his own drinking cup, as many do already. The railroads can scarcely be held responsible for a danger to which they do not contribute more directly than they do to this and in which they follow a custom so generally followed and demanded by the public. The common drinking cup is universal. The evil it contains does not exist in its worst form in well-regulated cars where the cups are or should be, frequently cleaned. There are ways of drinking from a cup which render the probability of contamination very slight. Most people are careless in this as in other personal habits. Rinsing and a clean towel will make almost any cup harmless however if the user cares to take so much trouble.

The drinking water should be the purest locally obtainable, it should be cooled by ice from sources of a pure supply, which should be well washed before putting into the tanks and handled only from clean receptacles with tongs or clean gloved hands. The water cooler should be removable and cleansable and protected from possible contamination by car occupants. They should be frequently scoured and steamed. These are clear-cut duties of the railroad or car company and distinctly apart from the hygienic duties of the traveling public.

3. Hangings, linen and bedding are, in general appurtenances of sleeping cars only. What part are they likely to play in the indirect transmission of disease? Linen may be at once dismissed from consideration since it is always fresh to the user. So far as any single trip is concerned the hangings and beds belong in lots to single individuals and the consideration of their possible danger to the health of the traveler brings us to the discussion of the third element of the danger of infection in railway travel namely the possibility of the car itself being infected in such a way as to transmit disease to its occupants. This is dealing simply with a new phase of the question of indirect transmission of disease—indirect transmission from previous passengers or from extraneous sources.

Some investigation of this problem has been made in both this country and in Europe. The investigation of Kinyoun⁴ above referred to included 1, The bacterial content of the dust from carpets, 2, the bacteria obtained from the interior furnishings of the coach, 3, the bacterial content of the air of the coach and 4, the bacteria of the drinking cup already referred to.

It is worth while to mention the results of these examinations. Dust was obtained from 260 cars and 100 passengers' cars. The results were as follows: 1, The bacterial content of the dust from carpets, 2, the bacteria obtained from the interior furnishings of the coach, 3, the bacterial content of the air of the coach and 4, the bacteria of the drinking cup already referred to.

³ S. Moeller, Med. Wochenschr., 1907, xiv.
⁴ The Bacterial Content of the Railway Coach, Med. News, July 22, 1911.

with compressed air. In seven samples so obtained many varieties of bacteria were found, principally those ordinarily found in the air. Microscopic search failed to demonstrate the tubercle bacillus among them, and animal inoculations proved its absence. The pneumococcus, staphylococcus aureus, streptococcus and colon bacillus were the only pathogens found, of these the author says, "Only the pneumococcus proved pathogenic, and this but slightly so." Some of the inoculated animals, I find from the subsequent text, however, developed abscesses from staphylococcus infections, a result to be expected, no matter what the source of the dust.

Dust was collected from the interior furnishings of twenty-nine sleeping cars, three day coaches and two smoking cars by rubbing sterile moist swabs over not less than fifteen square feet of surface. Eleven of these cars were running to health resorts during the height of the travel. Microscopic examination of these samples showed them to contain various bacteria and the ordinary elements of the dust of habitations. Of numerous samples stained for the tubercle bacillus two gave positive tinctorial and morphologic results. Sixty-four animal inoculations gave 1 positive tuberculosis, 5 pneumococcus infections, 1 diphtheria, 2 staphylococcus, 2 streptococcus, 2 colon bacillus, 1 malignant edema, 1 streptothrix, and 6 hemorrhagic septicemia. Forty-three animals gave negative results.

Realizing that the pathogenic bacteria floating in the air are of greater relative importance than those with stationary lodgment, special attention was given to their examination. Amounts of air ranging from 1,500 to 7,200 cubic feet were aspirated from forty-eight occupied coaches, twenty-seven running to and from health resorts, and its dust filtered out and subjected to analysis. The author says: "The majority of the bacteria found in the air evidently had their origin, as would naturally be expected, from the outside air." Ninety-six animal inoculations were made which resulted as follows: Tuberculosis 1, pneumococcus infection 8, staphylococcus infection 4, general septicemia 5, malignant edema 1, negative 76. The pneumococcal infections were obtained from the air of smoking cars almost entirely.

Prausnitz¹⁰ and Petri¹¹ were able to demonstrate tubercle bacilli in cars carrying many consumptive patients to the health resorts of Switzerland and to Berlin during the first activity of Koch's tuberculin treatment. They were found chiefly on the floors as the result of spitting, an evil which our widespread crusades has materially lessened in the last few years.

Every space occupied by human beings is to a certain degree infected, as are all the individuals themselves. The colon bacillus, for instance, is a normal inhabitant of the human body. It appears in the intestines soon after birth and is not thereafter absent. Ordinarily it is harmless, perhaps even useful to the bodily functions, though under certain conditions it may take on virulent activities and give rise to pathologic processes. We expect to find it more or less generally distributed where human beings exist, otherwise the child would not become uniformly infected in the first few days of its life. Its existence in the railway coach is scarcely more than normal. "The pneumococcus is present in the nose, mouth and pharynx of a large percentage of individuals. It persists for weeks and months in the

mouths of convalescents from pneumonia, and it reaches the mouths of those who are in the vicinity of pneumonics. It is found frequently in the conjunctiva and occasionally in the deeper air passages."¹² Knowing this organism to be fairly constant in the upper respiratory passages of normal individuals, we should expect to find it fairly constant in the places they inhabit. Having but little resistance outside the body it soon dies off, but occupied places are being constantly reinfected. Concerning the unusual conditions that must arise to precipitate infection of the pulmonary tissues we have little but theories. Certain it is that attempts should be made to lessen its distribution, this can be done only by care on the part of those who harbor it.

So far as the staphylococcus is concerned, it is widely distributed in nature. We all expect to find it on our hands, consequently on the things our hands pick up. Almost as much may be said of the streptococcus. It may be usually cultivated from the normal mouth cavity. Streptothrix is also frequently found in the normal mouth and usually is harmless there. The bacillus of malignant edema is normal in garden earth, which we handle with impunity. To introduce it into the peritoneal cavity is another matter. Hemorrhagic septicemia is produced by various organisms, which are more or less widely distributed in nature, and is not ordinarily an infection easily acquired.

Diphtheria bacilli may persist in the nose and pharynx of convalescents for weeks and months, continuing long after recovery. They are frequently found in the upper air passages of healthy persons who may never have had diphtheria, but who have been in contact with the diseased. Kober¹³ obtained virulent bacilli from 8 per cent of individuals who had been in direct contact with patients, and he states that 0.83 per cent of the people at large carry with them virulent organisms. Ustvedt¹⁴ found 4.5 per cent of 4,277 school children to be infected, and he quotes Geirsvold, Graham-Smith, Leegard and others as reporting percentages of infection ranging from 2 per cent to 30 per cent of those examined. It is furthermore well known that many sore throats of benign type are really caused by the diphtheria bacillus. Wassermann¹⁵ has shown that the blood of a large proportion of both children and adults contains diphtheria antitoxin, even when there is no history of the disease. These facts furnish ample explanation for the finding of the organism in cars and other places where people congregate and the practical impossibility of preventing such findings. The diphtheria bacillus is an obligate parasite, having no vegetative existence outside the body. Infection takes place chiefly by direct contact. It may occur also by indirect contact or, presumably, by the dust from infected fomites, since the organism may remain virulent for a considerable period in the dried state. With the vast number of infected throats among the general population the inference of indirect contagion is not only unnecessary to explain the cases that arise, but without clear and direct evidence of such a mode of infection is scarcely a logical supposition. Though I can not accept Chapin's¹⁶ view that

¹² Ricketts loc. cit. p. 839.

infection by fomites is among the great rarities and that disinfection is unnecessary still he has sounded a timely sentiment in urging the relative infrequency of the transmission of contagious diseases by inanimate objects, and has called attention to more fundamental, if not more important, means of control than fumigation. He quite correctly looks on the infected individual as a far more dangerous source of transmission than the things this individual has used or the place he has occupied.

In view of the fact that about 15 per cent of all people die of tuberculosis and that 80 per cent or 90 per cent of autopsies show evidence of healed tuberculous lesions, and that a large proportion of the afflicted associate with the healthy and distribute their infected sputum with indifference, it is a surprising element of Kinyoun's results that he succeeded in producing the disease in only two of 160 animals inoculated. It is not surprising that car sweepings, dust and furnishings are now and then infected with the tubercle bacillus. Any public place is likely to be so. Under present conditions we must expect it. We all understand that the procedure necessary to most successfully combat the evil is to prevent spitting any place where the sun does not shine. The remedy is personal cleanliness.

The results obtained in the investigation of railway coach bacteriology up to this time are in the main what might have been expected. It is not possible, however, to draw conclusions from them which will finally establish the relations between the railway coach and disease without adding vastly to the experimental evidence which they contain. It is desirable to know something of the average absolute number of pathogenic bacteria and their relation to the whole number present, their ratio to the number of passengers and to the length of trips, the relation between the internal air and the surrounding air of the moving train and to compare these results with those obtained by investigating other inhabited places. If the car contains only the organisms absolute and relative found in other similarly inhabited places, the problem then becomes one of altering conditions of infection generally, the car sinks into the relative insignificance of its small proportion of the whole and is merged in the general combat. If on the other hand the car is found to be burdened with pathogenic bacteria in excess of other places, it then becomes a problem calling for special methods of solution and special care in its handling. The time and labor required to determine these things is necessarily great on account of the many factors entering into the problem as it concerns the coach in transit.

It is of course, hopeless to attempt to keep cars sterile or free from even pathogenic bacteria nor is this necessary in order that they may be safe. In order to acquire an infectious disease we must receive organisms in sufficient quantity and of a sufficient degree of virulence. We must also have a resistance low enough to permit infection to take place, and having that we may ourselves harbor the very germs that await the critical moment.

Though we must expect most cars to contain pathogenic micro-organisms in greater or lesser numbers it is nevertheless desirable that the railroads should take precautions to reduce them to a minimum. Good mechanical cleaning is of first importance. Remove dust and dirt or excreta that may become dust and most of the bacteria greatly considered will be removed with it.

Beat or blow with an air blast the seats and carpets outside the car if possible. It will not remove the last particle of dust but if it is well done not enough will be raised from them in ordinary use to afford danger of infection to the car occupants. Scrub the floors with basins and closets and disinfect them regularly. Wipe down the woodwork. Expose bedding to the disinfecting influences of air and sunlight and to beating and blowing. If the sick have occupied coaches or sleeping cars fumigate them at the end of the run. In addition, regular fumigation at stated intervals is indicated simply as a prophylactic measure. There has been applied to the Pullman service within the past year a system embracing all these measures and one which in my judgment meets the more important requirements for the maintenance of sanitary cars. Much labor is expended in removing dust much time is given to sunning and airing smoking rooms and closets basins and cupboards are washed daily with disinfectants, cars that have carried the sick are fumigated, all cars are fumigated monthly and those running to health resorts weekly or oftener. The public has a supplementary duty and the members of the medical profession a complementary one, educate the social body to an appreciation of its own power of self preservation.

THE MORE INDIRECT DANGERS

Third—The miscellaneous influences constituting the third group of the dangers of railway travel as I have outlined them affect the health of car occupants only indirectly as a rule and tend to reduce resistance rather than to produce disease directly. Certain individuals have peculiar susceptibilities of the nervous system rendering them liable to the so-called "car-sickness" during any long railroad journey. There are people too who almost invariably have attacks of migraine under similar conditions. It is not possible to entirely prevent these results of rapid train motion in the predisposed though smooth roadbeds and comfortable cars probably tend to lessen the liability of their occurrence.

The ventilation of cars is a vital problem. That it has not been satisfactorily solved long ago is due to its great mechanical difficulties. The car contains and must contain a minimum of space for a maximum number of occupants. The swift and changing motion of the train its constantly changing direction and wind conditions its rapid transit from cold to warm or warm to cold regions the necessity of changing the air frequently the consequent great liability to draughts and the variable sentiments of the passengers who must all accept the same amount of air make up a combination of conditions difficult to manage. The real difficulty arises of course when the outside temperature is low. Summer ventilation is scarcely a problem. We all know that cars often seem to be ill ventilated and "stuffy" but as a matter of fact we do not know just how good or how poor is the average of car air from the clinical standpoint. A series of experiments is now under way to determine this. The results of the experiments will be made the subject of a future communication.

Remaining long in an atmosphere heavily laden with the products of respiration may produce headache, drowsiness, nausea and general malaise. Similar results may come from a close, overheated moist atmosphere even though its chemical purity is sufficient for every hygienic demand. Indeed, recent experiments have

Flugge,¹⁷ Heymann,¹⁸ Paul,¹⁹ Ercklentz²⁰ and others go to show that high temperature, much moisture and air stagnation are alone responsible for the deleterious influences of faulty ventilation, and that chemical impurity of the air plays no part in them except under the most extraordinary conditions. A strong opponent of this view among recent writers is Wolpert,²¹ who maintains that metabolism is hindered by a much breathed atmosphere. Whatever the explanation, it seems to be certain however, that poor ventilation is ordinarily not harmless, and that in addition to the temporary symptoms of discomfort, the long occupancy of so-called "stuffy" rooms so lowers resistance as to be conducive to the contraction of colds and perhaps also to the more serious infections. But draughts of cold air are equally depressing, and the problem is to find the means of introducing enough air to maintain comfort and not enough to produce danger from exposure.

Heating is a problem going hand in hand with ventilation. With the present means at our command it needs but care and intelligent operation to maintain a proper temperature in the closed car. With the attempt to change the air frequently, however, the difficulty is many times increased, for the reason that the entering air is so liable to great variation in amount and temperature as indicated above. If Flugge and his followers are right in their contention that the relation existing between temperature and moisture and the motion of the air are responsible for the whole of the bad effects of ill ventilation, then the problem of heating becomes relatively more important than it has heretofore been considered and ventilation relatively less important.

A certain amount of dust and smoke and locomotive gases inevitably enter the train. These are, of course, liable to great variation, but smoke and gases are not really troublesome except in passing tunnels, when they produce no more than temporary discomfort. Ordinarily only the heavier particles of smoke—the small cinders—enter the car, the lighter solid particles and the gases floating upward and away with the wind. If we are forced to breathe much smoke for prolonged periods it acts as a mechanical irritant and exerts a harmful influence upon the respiratory passages. Ascher²² of Königsberg published a series of experiments on animals showing that it both hastens the fatality of tuberculosis and predisposes to acute infections of the lungs, and he arrives at similar conclusions concerning human beings from a study of the vital statistics in relation to smoke production in the manufacturing towns of Prussia.

Ordinary dust is of more importance because it is more prevalent and because it may be infectious. It comes chiefly from the railway tracks, and their nearly universal free exposure to the sunlight makes it very probable that any pathogens will be rendered innocuous before the dust stage of their container is reached. Track contamination is probably of greater danger to the consumers of the water of streams into which sewage may be washed before it has a chance to dry than to the users of cars. The mechanical irritation of dust is, however, of some importance. It may produce mild inflammation

directly, or it may lower the resistance of the mucous membranes of the respiratory passages to the point of favoring infections. Certain dusts, as those of the alkali deserts, which are soluble in the secretions, may act as chemical irritants. Sprinkling of the track with oil, as is practiced by some railroads, is, therefore, a salutary measure from a hygienic standpoint. To convert dust into something else than dust removes the difficulty in the best way, and is in the end the simplest. Of next efficiency would be some air filtering device.

It need scarcely be said, in conclusion, that it has been the author's purpose rather to define and to estimate the importance of the various problems of car sanitation than to detail their solution. That there is always a slight danger of acquiring infectious diseases in railway coaches can not be denied. That this danger is chiefly dependent on direct contagion in the close personal association of passengers seems probable, while indirect transmission through the common use of facilities for comfort or by the infected car is of secondary importance only.

An attempt has been made to show why it is that personal hygiene is a most important element in the solution of the problems of car sanitation and why the co-operation of travelers is necessary to an effective combat against the contraction of infectious diseases in cars. This statement must not be interpreted as a defense of the railway company which does not take every reasonable precaution to maintain its cars in a sanitary condition, or does not provide facilities whereby the liability of the transmission of infectious diseases may be reduced to a minimum. The duties of the railway in this regard are perfectly clear, and their fulfillment is essential to the maintenance of the public health. Bad habits in matters of personal hygiene are due largely to ignorance. It is the correction of this very general ignorance in the public at large that must supplement the best car sanitation in order to bring it to a high degree of efficiency in protecting those who travel.

CHRONIC ARTICULAR RHEUMATISM AND ARTHRITIS DEFORMANS *

PROF. A. HOFFA.

ASSISTED BY DR. G. A. WOLLENBERG
BERLIN

I wish to present some researches on the subject of chronic articular rheumatism and arthritis deformans which I have been making for a number of years, with the cooperation of my assistant, Dr. Wollenberg. By some authors, especially surgeons, chronic articular rheumatism is distinctly separated from arthritis deformans, while another group, chiefly internists, refuse to accept this distinction.

Take a concrete case, a woman of 35, affected with a chronic joint disease. The disease first involved symmetrically the joints of the fingers and toes. Slowly and without fever, the affection spread in paroxysmal attacks from the finger joints to the wrists, elbows, ankles and knees. At length the patient became entirely helpless, she was confined to an invalid chair or to her bed permanently. The disease was chronic from the beginning, no valvular affection arose and the patient did not react to salicylic acid.

What position does this affection assume in pathology?

* Abbreviation of an address delivered February, 1907, before the Anglo-American Medical Association of Berlin.

It has been variously designated chronic articular rheumatism, arthritis nodosa, polyarthritis chronica villosa, rheumatoid arthritis, etc

I wish to give you the proof from clinical, radiologic and pathologic-anatomic sources, that it is an affection *sui generis*, to be sharply separated from arthritis deformans. Let me designate this disease as polyarthritis chronica progressiva primitiva, or, in order to distinguish it from arthritis deformans, simply as arthritis destruens, because the destruction of the joint ends is characteristic of the disease. The term rheumatism is dropped, since there is a chronic articular rheumatism occurring as a sequela of acute articular rheumatism, but presenting in its acute or subacute onset a different clinical picture from the disease under consideration. Furthermore, I drop the term deformans, as we have not to deal with an alteration of the joint characterized by atrophy of the bone and cartilage on the one hand, and proliferation of cartilage and bone on the other, but with an actual destruction of the joint itself. We shall see that oc-

If the joints be inflated with oxygen the soft parts of the joints are made visible, and in such an oxygen float gen ray picture the changes already described are seen, and in addition it is shown that the upper recessus of the joint is well preserved. There is never such a breaking down of the joint as is characteristic of polyarthritis chronica progressiva, in which an obliteration of the joint cavity is the rule.

In the clinical course of polyarthritis chronica progressiva the marked characteristics are the progressive character, its beginning in the small joints and spreading to the larger ones, deformities of various types, and especially the high grade of muscular atrophy. All graphs show extremely characteristic changes.

Above all, an extraordinarily high degree of atrophy of the bone striations. In addition, the breaking down of the cartilage is significant. The outlines of the joints disappear, the extremities of the bones are joined one on another, and, where the latter are lying on one another, defects and enlargements are found. The enlargements

the function of the limbs plays a rôle. If you observe how the patients use their hands, you will see that they try to pick up a thing from the table by grasping it with their pronated hands, consequently, the fingers must be deviated to the ulnar side. In the same way the hyperextension in the interphalangeal points is easily explained by the patients bracing their fingers, in the use of their hands, with the tips on the table, etc.

The consideration of the Roentgen ray plates has shown us that in arthritis deformans and in chronic progressive polyarthritis we have to do with two entirely different diseases.

Entering now into the consideration of the pathologic-anatomic differences of the two affections, our researches in this direction have resulted in the following:

1 *Arthritis Deformans* (in the sense of v. Volkmann) —The pathologic process manifests itself first in the cartilage and in the bone, while the synovialis in the beginning only shows insignificant alterations. If the appearance of dentation and of proliferation at the cartilage are already well marked, we see at the synovialis only a simple hyperplasia of villi with a slight new formation of vessels and connective tissue. Only when the cartilaginous and bony parts of the joint are strongly altered, when extensive destructions, polished surfaces and glandular proliferations of the margin are present, do the above-described alterations at the synovialis become more distinctly marked.

The inflammatory signs on the synovial membrane, however, are but slight, only rarely few small accumulations of lymphocytes occur, but never nearly as much as in the earlier stages of the primary chronic polyarthritis. On the contrary, in the later stages of arthritis deformans degenerative processes of the synovialis, especially hyaline degeneration, become more prominent. Thus the entire synovialis may be changed into a structureless hyaline tissue. Furthermore, calcification and pigment deposits (intracellularly and extracellularly) are often found.

If we compare these alterations with other pathologic processes of the synovialis, they resemble mostly the anatomic pictures of traumatic synovial affections, which we have had frequent opportunity to observe, and we are therefore inclined to refer a great part of the anatomic alterations of the synovia in arthritis deformans to an "internal trauma," to which the synovial membrane is exposed in every movement.

2 *Primary Chronic Progressive Polyarthritis* —The pathologic process begins here in the strictest contradistinction to arthritis deformans in the synovialis, whereas the cartilage at first shows no alteration. In the earlier stages of the disease we observe a far more marked proliferation of villi of the synovialis, a far more copious new formation of vessels, a far greater proliferation of the fixed connective tissue cells, than we meet with even in the more advanced stages of arthritis deformans, most significant, however, are large accumulations of round cells lying close to one another, representing mostly circumscribed, perivascular, lymphoma-shaped formations, in addition, we find here and there a diffuse infiltration of the tissue with lymphocytes.

These lymphoma-shaped, round-cell accumulations are also found in various other diseases of the joints, but there they are almost never so numerous and dense, of course, they are not specific, and are especially sharply distinct from tuberculous nodules. Alterations of the cartilage and of the bone are in these early stages either not present, or they have a purely regressive character, as the cartilage undergoes destruction, shows erosions, or is

substituted by a pannus-shaped granulation tissue, originating from the synovia. Thus the cartilaginous surface is gradually transformed into connective tissue.

In later stages, also apparently slight symptoms of proliferation may occur, especially in mild cases. Under the influence of the granulation tissue covering the cartilage, a slight swelling of the interstitial substance of the cartilage may arise. A real proliferation of cartilaginous cells, however, we could only find in a slight degree. At the margin of the cartilage the corticalis is perforated and granulation tissue, likewise originating from the synovialis, infiltrates the marrow cavity.

In very late stages of the affection we finally find a strong connective tissue thickening and a shrinking of the joint capsule, furthermore, a more or less complete fusion of the portions of synovialis opposite to one another and of the articular extremities. Everywhere in the neighborhood of the surfaces of fusion we find more or less copious accumulations of lymphocytes and infiltrations. The cartilage is now entirely or almost entirely broken down or substituted by connective tissue so that often only a thin lamina of connective tissue forms the outline of the marrow cavity, since the corticalis of the bone is also extensively destroyed. The bony ends of the joint are markedly diminished in size, their spongiosa being extremely rarified and altered into scanty, very thin trabeculae. Proliferations of the bones and of the cartilage we have not been able to ascertain.

If we compare these anatomic alterations with those of other joint diseases, a great resemblance of the lesions of the synovialis with those in infectious arthritis of a known etiology, as, for instance, in gonorrheal arthritis, is manifest.

In arthritis deformans we have to deal with a primary affection of the skeleton parts of the joint, in polyarthritis progressiva, on the contrary, with a primary affection of the soft parts of the joint. According to our statements, we must, therefore, insist on definitely separating these two forms of disease.

My classification of chronic joint diseases on an etiologic basis would therefore be as follows:

- A Non infectious chronic joint diseases
 - 1 Traumatic arthritis chronica
 - 2 Irritative arthritis chronica (Hydrarthros chronicus)
 - 3 Constitutional or dyscratic arthritis chronica
 - (a) Gout (b) hemophilia.
 - 4 Arthritis deformans
 - (a) Spontaneous (b) reactive (c) neuropathic.
 - 5 Functional arthritis chronica (Joint neuralgia intermittent hydrops)
- B Infectious chronic joint-diseases
 - 1 Primary infectious chronic joint-diseases
 - (a) Polyarthritis chronica progressiva primitiva or destruens.
 - 2 Secondary infectious chronic joint diseases
 - (a) Secondary chronic joint rheumatism following an acute joint rheumatism (b) Chronic joint diseases after acute infectious diseases gonorrhoea scarlatina measles etc (c) tuberculosis (d) syphilis

This is only an attempt to classify chronic joint diseases etiologically, for in a number of cases of the diseases concerned the etiology is still hypothetical. As long as we have nothing better, we must be content to inaugurate the progress, and progress can only be made by recognizing the etiology of our affections. In this direction, therefore, our further researches have to be carried out.

Concerning the prognosis of our disease, I do not wish to enter into details. But I would like to add some remarks on therapeutics. You all know that in these chronic diseases, besides salicylic acid and other drugs, the whole arsenal of physical therapy has been tried, hot air, massage, gymnastics, various poultices and packings, baths, etc., however, as a rule, with no great success. In arthritis deformans I have often obtained good

results with supporting apparatus for the hip as well as for the knee and for the foot, after all other means had failed. This is well known. In very much advanced cases, where even supporting apparatus did not help, I finally decided to perform the resection of the articular extremities of the hip and of the knee, and have here obtained good results.

The treatment of polyarthritis destruens is more difficult. All the measures of physical therapy have been tried unsuccessfully. I have repeatedly performed arthrectomy, especially of the knee, but with no good results beyond slight improvement in the symptoms. On the other hand, I obtained good results, that is to say, I enabled patients to walk even when contractures were far advanced, by supporting apparatus applied after stretching the contractures and fixing the legs in the stretched position. The leather must extend over the knee joints in such a way as to give them a real support. Then the patients receive side supports and by means of these and of special stretching apparatus one can gradually stretch the legs entirely straight. The supports of the knee are made movable only when the disease has improved so far that the swelling of the joints has considerably decreased and the pains have entirely disappeared. I advise, however, not to do this too early, as otherwise relapses may readily occur. I have found that it is best to assist the apparatus treatment by a course of mud baths. When the legs are stretched, the atrophied muscles are strengthened by daily massage, and finally the patients can put away their machines entirely after some years without fearing any relapse.

THE DEVELOPMENT OF CARDIAC MURMURS DURING ATTACKS OF BILIARY COLIC *

DAVID RIESMAN, M.D.

Professor of Clinical Medicine, Philadelphia Polyclinic, Associate in Medicine, University of Pennsylvania. Physician to the Philadelphia General Hospital.

PHILADELPHIA

In two cases I have had the opportunity of observing, a systolic murmur, not previously present, was heard during or soon after an attack of biliary colic. The first case was in a woman, a doctor's mother, sixty-one years of age, who had had her first attack of gallstone colic eighteen years before. I saw her in a typical seizure, the third within a few days, as a sequel to which she passed five faceted stones. At the first examination I discovered a loud, systolic murmur at the apex, which the doctor assured me had not been present before. There was no accentuation of the second pulmonic sound. The murmur persisted for nine days, the jaundice, which was pronounced, lasted only four days. After an interval of two years, during which the patient was very well, she had another attack of biliary colic with jaundice, but without murmur, and without the passage of stones. An operation, the advisability of which had been considered was rejected. Two months later another attack occurred and in this one the patient died. The jaundice was decided in all the attacks, the murmur was present in only one, and in only one was there any itching, and then of slight degree.

The second case I saw with Dr. E. Landauer Oct. 29, 1906. The patient was a man 52 years of age, a tobacco stripper, whom I had seen some weeks previously on account of a persistent pain in the right

hypochondrium, at that time his heart was normal, except for accentuation of the second aortic sound. October 20 he had a violent attack of biliary colic, followed by deep jaundice and three separate seizures of chills and fever without sweating, there was no itching. On examination I found in the mitral area a loud, blowing murmur which Dr. Landauer tells me he first noticed October 24. The cardiac boundary was enlarged to the left and ran outside the left nipple line, the liver extended a hand's breadth below the costal arch, but was not tender, the urine was deeply bile-stained, the feces clay-colored. A diagnosis of stone in the common duct was made. I did not see the patient again but I am informed by Dr. Landauer that at the operation on November 1 a large, solitary, ovoid stone was found in the common duct. The jaundice which had been very pronounced, rapidly disappeared, the murmur is still present although the heart outline is practically normal.¹

In the literature there are but few references to murmurs in connection with gallstone disease or with jaundice. Gangolphe² calls attention to the subject and reports nine cases, of which four were examples of cholelithiasis, two were cases of emotional jaundice so-called, two of cancer of the liver, and one of cholangitis. I will give brief summaries of these cases.

CASE 1—Male, aged 21, two weeks before admission to the hospital, nearly lost his life in aiding an injured man. Since that time there had been malaise followed by jaundice, with tenderness in the hepatic region. There was palpitation of the heart, strong impulse, no enlargement of the boundary. A systolic murmur could be heard at the mitral and tricuspid areas. Four days later a systolic murmur developed in the aortic area transmitted into the cervical arteries, a month later the murmurs had all disappeared, and the patient left the hospital.

CASE 2—Female, aged 31, had always been well except for repeated attacks of hepatic colic, followed by jaundice. The last attack occurred ten days previously. There was no fever, but there were slight jaundice, tenderness and a small tumor in the gall bladder region. There was a systolic murmur at the apex, the latter being normal in position, no appreciable change could be made out in the volume of the heart, the murmur lasted twenty-two days.

CASE 3—Female, aged 57, had cancer of the liver. There was slight jaundice. A systolic, apical murmur appeared eighteen days after entrance into hospital.

CASE 4—Male, aged 39, had hepatic colic, subfebrile temperature and bradycardia. A systolic murmur at the base was audible in the vessels of the neck; a systolic murmur at the apex appeared coincident with the onset of the bradycardia.

CASE 5—Female, aged 51, had emotional jaundice following fright, a systolic murmur was present at apex. Eleven days after admission to hospital the murmur was very faint and eventually disappeared entirely.

CASE 6—Female, aged 26, had hepatic colic. A systolic murmur was present heard best in the third interspace to the right of the sternum and was transmitted into the vessels of neck. A systolic murmur of the same quality was heard at the apex but was not transmitted to the axilla. There was no fever, pulse was 68. Six days later the murmur and icterus grew fainter and the patient felt well and demanded her discharge.

CASE 7—Male, aged 54, had cancer of the liver with inflammation of neighboring structures. There was fever at first, intermittent then remittent. A systolic murmur was heard at the apex with doubling of the first sound.

CASE 8—Male, aged 34, had hepatic colic. He was admitted

* Read before the Section in Medicine of the College of Physicians of Philadelphia, Dec. 10, 1906.

1 On December 19, fifty-one days after my visit, I saw the patient again. He seemed to be entirely well, the murmur had disappeared.

2 Du bruit de souffle mitral dans l'ictère. *Th. de Paris*, 1877.

August 20, with jaundice and generalized itching. A systolic apical murmur appeared seven days later, the pulse then was 40. By September 7 the murmur had disappeared.

CASE 9.—Male, age not given, had catarrhal jaundice. He entered the hospital July 12 with no murmurs and temperature 39.1 C (102.3 F), pulse 112. On July 19 there was no fever, pulse was 70, a systolic murmur was present. July 22 pulse was 56 and the systolic murmur was loud. On July 25 the murmur was still audible, the jaundice had lessened. By July 30 the murmur had disappeared.

Fabre,³ among eight cases of jaundice, found the heart affected in five, but gives only meager details regarding them. In an elaborate monograph Rendu⁴ mentions a case of hepatic colic in which a systolic murmur appeared. A woman, aged 57, had repeated attacks of colic, in the last one dilatation of the heart with the production of a systolic murmur supervened, and ended in death. In another case of hepatic colic with jaundice there was marked arrhythmia, and in one of catarrhal icterus, a gallop rhythm without arrhythmia. Rendu also cites a case of Potain's, in which all the signs of tricuspid insufficiency were found without the classical causes for that condition. The patient had had repeated attacks of hepatic colic, and it was during one of particular violence that the signs of cardiac disturbance manifested themselves. Treatment directed to the cholelithiasis caused disappearance of all symptoms, including the tricuspid murmur. Potain⁵ and Rendu both believed that the murmur had its origin in the right heart and was due to a transitory dilatation of the right ventricle.

Tessier⁶ classifies the cardiac disturbances depending on gastrohepatic disease as follows: 1. Unusual loudness of the second sound. 2. Doubling of the second sound. 3. Tricuspid murmur. 4. Complete tricuspid insufficiency with venous pulse. This indicates that he, too, thinks the murmur is produced at the tricuspid valve.

Guéneau de Mussy,⁷ for whom Revillout claims priority in the discovery of cardiac murmurs in jaundice, attribute the murmur to a paralyzing effect of the bile salts on the vasomotors and the general circulatory system. Gangolphe considers the principal factor to be a paralysis of the papillary muscles, while Fabre looks on myocarditis produced by the accumulation of biliary salts and acids in the blood as the essential change. Quincke,⁸ who observed the murmur as well as accentuation of the second pulmonic sound, believes it to be no more frequent in icterus than in other conditions in which the general health is impaired.

There are various ways in which a murmur may be produced in cholelithiasis and jaundice:

1. By a true endocarditis, such as may readily be caused by any septic process in the hepatic region, as empyema of the gall bladder or suppurative cholangitis.

2. By anemia.

3. By altered chemism of the blood apart from anemia.

4. By dilatation of the heart and other changes in the myocardium, as e. g., paralysis of the papillary muscles.

The transitory character of the murmur, together with the absence of any signs indicating grave infective lesions in the region of the liver, renders it unlikely that the murmur is due to an acute endocarditis. Anemia can hardly be a factor of importance, the murmur

comes on too early, long before any signs of grave impairment of health manifest themselves. It can scarcely be that the jaundice is responsible for the murmur in cases like those I have described, otherwise such murmurs would be more common. I have purposely examined a considerable number of jaundice cases, but have not detected a murmur in any save the two mentioned. Among them were cases of deep jaundice that had persisted for several months with decided detriment to the general health, and yet there was no murmur. Moreover, the murmur usually outlasts the jaundice. If the jaundice has nothing to do with it, do the bile acids and bile salts play any rôle? I do not think they do in the sense that they alter the chemism of the blood as anemia does, but they may cause changes in the myocardium or in the innervation of the heart, it being agreed that they are responsible for the slowing of the pulse.

One point of importance remains, namely, the pain, and this I hold to be the principal factor in the production of the murmur in cases of hepatic colic. The pain, which is proverbially of the most agonizing character, in the predisposed, causes dilatation of the heart with a temporary insufficiency of the mitral valve, perhaps, also, of the tricuspid. I said "in the predisposed," because if pain were the only etiologic agent, then every case of biliary colic ought to have a murmur. The heart must be potentially dilatable.

This theory, or hypothesis, fails to account for the murmur in Gangolphe's cases of emotional jaundice, and for that sometimes seen in catarrhal jaundice and in cancer of the liver. With regard to the last, I think that anemia and cachexia are an adequate explanation. What the factors are in the rather dubious emotional jaundice I am not able to say, personally I have not met with any such cases, nor have I heard the murmur in question in cases of catarrhal jaundice.

A word as to the practical importance of the murmur. If its mode of production is as I have stated, then its presence indicates that the musculature of the heart is not entirely normal, and, therefore, it enforces some caution in the choice of the anesthetic, perhaps in that of the operative technic itself. A prolonged operation might be dangerous. On the other hand, the discovery of the murmur might lead to the erroneous belief that an old endocarditis existed, a belief that would probably influence the decision of the physician or surgeon. It is evident from these considerations that the knowledge that a systolic murmur might arise *de novo* in cases of biliary colic and that it is an index of a weakened myocardium—a weakness that may not be serious—will be of value in the management of a given case.

TORSION OF THE GREAT OMENTUM

WITH REPORT OF A CASE *

W. W. RICHARDSON, M.D.

Professor of Anatomy, College of Medicine, University of Southern California

LOS ANGELES, CAL.

The full value of the following case has suffered by my neglect to report it when the literature on the subject was scant. It is with the hope that even this delayed report may be of value that it is now given, with some remarks on the subject based on the literature which I have been able to secure.

Patient—Mrs. J. K. Austrian, aged 34, in para

⁷ Quoted by Revillout, Gaz. des hôp. 1878, 666.

⁸ Dis. of Liver, Nothnagel's Practice, English Translation, p. 438.

History—I first saw her in 1893 during an attack of acute abdominal pain and discovered an ovarian tumor about the size of an adult head. The attacks of abdominal pain were repeated at frequent intervals. In January, 1894, she had two attacks of this pain and in February three. She gradually lost strength and flesh and the tumor slowly enlarged. February 23 an unusually severe attack of the pain drove her to consent to operation.

Operation—March 2, 1894, the abdomen was opened by a median incision six inches long, below the umbilicus. The tumor, which was intensely congested and rather firmly adherent to the parietal peritoneum and intestines, was removed with some difficulty. The pedicle was about two inches long by three inches wide, and was twisted on its long axis, from left to right. The tumor was a multilocular ovarian cyst with thick walls of a dark bluish color, and contained about one gallon of dark bluish, almost black fluid, as the result of the strangulation at the pedicle. It was noticed that the uterus was enlarged to the size of a large orange and was soft. The parietal and intestinal peritoneum was lusterless, velvety and bluish red and the abdomen contained a small quantity of fluid. The incision was closed by through and through sutures of silk and a glass drainage tube was left in for forty-eight hours. Recovery was uneventful and she left the hospital on the eighteenth day.

Postoperative History—In April it was noticed that the uterus was enlarged, and in May it was nearly to the umbilicus. August 15 she gave birth, unattended, to a large male child. About one year after the birth of the child a hernia developed in the laparotomy wound, and in June, 1901, an abdominal binder and pad was applied. The hernia was then about the size of a small orange, easily reducible and caused little inconvenience. July 14, 1901, she found it impossible to reduce the hernia, and there was some pain, but no vomiting. On the following day the pain increased and there was no passage from the bowels. July 16 I saw her and found a fat woman, with pendulous abdomen, who appeared very sick. She had vomited that morning, and the pain in the abdomen was severe. Her pulse was 140. The hernia was about midway between the umbilicus and pubes, about the size of an orange, it was hard and tender to the touch. There was slight redness over a small area and increased local temperature. No attempt was made at reduction. She was removed to the hospital and operated on at once.

Second Operation—The hernial sac was thickened and of a dull reddish color. The contents of the sac consisted wholly of omentum, matted into a solid mass, bluish black in color and adherent everywhere by recent adhesions to the sac and the hernial ring. There was no pedicle and apparently no constriction at the ring, which was about two inches in diameter. On loosening the adhesions at the ring it was found that the hernial mass was directly continuous with a mass of similar appearance within the abdomen. This intra abdominal mass was delivered with some difficulty through the hernial ring but without enlarging it. It was not adherent within the abdomen except at the hernial ring, and came out like a cork from a bottle, revealing a pedicle no larger than a goose quill, about two inches long and twisted several times on its long axis. The omentum proximal to the pedicle was of normal appearance but the distal mass was intensely engorged and matted into a solid mass.

The pedicle was ligated and the mass removed. The abdomen contained considerable bloody fluid but there was no peritonitis. Radical closure of the hernia followed and recovery was uneventful. The mass removed was in size and appearance not unlike an average placenta. No notes were taken of the number nor direction of the twists in the pedicle.

HISTORICAL

The first mention of torsion of the omentum in the literature is the report of a case by Oberst.¹ Ten years passed before the second case was reported that of Demons.² A silence of five years was followed by the re-

port of Bayer,³ of Monod⁴ and Eiselsberg.⁵ In 1899 Eitel of Minnesota⁶ reported a case which has been included in some of the collections and excluded from others.

In 1900 the reports became more frequent, and Wiener's⁷ valuable paper appeared attracting attention to the subject in this country, by reporting a case and reviewing five cases from the literature. In 1902 Moresco⁸ collected ten cases and reported one of his own. The following year Vignard and Giroudeau⁹ reported two cases of their own and collected twenty cases and in the same year Rudolf¹⁰ reported four cases from Schmitzler's clinic and collected twenty-five additional. Audier¹¹ in 1904 published a valuable thesis on the subject, with abstracts of twenty cases and a report of one. In 1905 Corner and Pinches,¹² in a valuable paper on the subject were able to collect fifty-four cases from the literature up to the end of 1904, including three new ones of their own and one of Makin's and a brief record of each of these cases was published in the St. Thomas' Hospital report for 1904.

In a very cursory review of the literature for 1905 and 1906 I have found reports of seven additional cases. The number of reported cases is now so large that a careful study of them will permit certain general conclusions to be drawn and although Corner and Pinches have covered the subject with thoroughness in their articles I hope that I may be able to add a little of value.

DEFINITION

The term torsion of the omentum should include only those cases in which twisting of the omentum on itself has caused a sufficient obstruction of the circulation to produce evidences of strangulation. The matting of the omentum into a mass or ball which precedes the torsion, although a part of the pathologic process, should not by itself be included under this term. Strangulation from any other cause than the twisting of the omentum on itself should also be excluded.

CLASSIFICATION

A sufficient number of well-described cases have been reported to permit a division into well-defined clinical and pathologic groups. A strictly clinical division into acute and chronic is warranted from the varying intensity of the symptoms which attract attention to the condition, although the pathologic changes which precede the appearance of the symptoms of strangulation are probably always chronic.

Among the chronic cases should be included those in which the torsion of the omentum has occurred gradually or has not reached such a degree as to cause great obstruction to the circulation. The venous return only is obstructed as is evidenced by venous engorgement and edema, but with the production of no acute symptoms of strangulation.

The number of chronic cases yet reported is small and they are of secondary interest as compared with the larger class of acute cases which are characterized by sudden onset and symptoms of acute strangulation.

ANATOMICO-PATHOLOGIC CLASSIFICATION

A study of the reported cases suggests a convenient classification from an anatomico-pathologic standpoint into two main groups, according as the point of torsion is within the sac of a hernia, or within the abdominal cavity. As some reported cases combine the two conditions, we may make a third class and divide all the cases into three groups

- 1 Torsio Omentalis Intrahernialis
- 2 Torsio Omentalis Intra abdominalis
- 3 Torsio Omentalis Intrahernialis et Intra abdominalis

In the first group are included those cases in which the point of torsion lies, at least in part, within the sac of a hernia, and the whole mass of strangulated omentum lies outside of the general abdominal cavity and within the hernial sac (Fig 1). The cases of this group are distinguished from strangulated epiplocele only by the absence of constriction at the hernial ring and by the presence of a twisted pedicle. The number of reported cases which may be included in this class is not large, but it is probably of fairly frequent occurrence, and has been mistaken for strangulated epiplocele. This same remark will apply with equal force to volvulus of the intestine, and Corner and Pinches have drawn attention to the frequency with which volvulus in strangulated intestinal hernia is found if sought for.

The second group, or intra-abdominal torsion, is char-

Fig 1—Torsio omentalis intra hernialis a, about one point, b about two points

acterized by the presence of a point of torsion lying altogether within the abdominal cavity (Fig 2). The strangulated omental mass may then be found altogether within the abdominal cavity (Fig 2, c) or partly within the abdomen and partly within the sac of a hernia (Fig 2, d), but not constricted at the hernial ring. Those cases in which no hernia was evident, or if present had no direct connection with the omental mass, are the purest examples of this group, but neither the existence or non-existence of a hernia, nor the presence or absence of part of the omental mass in the hernial sac are the distinguishing features of this class, according to my definition. It is not the situation of the omental mass, but the location of the point of torsion which determines the class. This class contains by far the largest number of the reported cases, as attention is attracted to the uncommon condition of strangulated omentum, within the abdominal cavity and the mechanism of the third class being more complicated, its actual frequency must be less.

The third class comprises those cases in which there exist two points of torsion, one lying within the cavity of the abdomen and one at least partially within the sac of a hernia (Fig 3). There will thus be formed one (Fig 3, g) or two (Fig 3, h) strangulated masses of

omentum according to the location of the distal point of torsion.

These three classes of torsion are based on the conditions as found at operation or autopsy in the published cases, but these conditions do not necessarily indicate the position of the omentum at the time of torsion, as classes one or three may be converted into class two by reduction of the omentum from the hernial sac into the abdomen, and the possibility of extrusion of an intra-abdominal mass into a hernial sac, after strangulation has occurred, is admissible.

As a subdivision of these main classes the classification of Vignard and Girondeau⁹ is useful as an indication of the mechanism of the torsion. They divide the cases into three groups according to the number and nature of the point of torsion.

Class A—Torsion about one point alone

Class B—Torsion about two separate points

Class C—Complex torsion

In Class A, torsion about one point alone are placed those cases in which the omentum has described one or

Fig 2—Torsio omentalis intra abdominalis c and d about one point e and f about two points

more revolutions on a vertical axis about one fixed point. There is thus found but one pedicle which may be intra-abdominal (Fig 2, c and d) or intrahernial (Fig 1, a), and but one strangulated mass. The majority of reported cases belong to this class.

In the cases of Class B the revolutions have taken place about two fixed points, and two pedicles are found both of which may lie in the abdomen (Fig 2, e and f), or both within a hernia (Fig 1, b), or, as has been frequently the case, one may be intra-abdominal and one at least partly within the sac of a hernia (Fig 3, g and h).

In these cases one or two strangulated masses are formed according to the mechanism of the torsion.

If the distal extremity of the omentum is attached by a small area to some fixed point the omentum is divided into but two parts, a proximal normal part and a distal strangulated mass, the latter being attached by

one pedicle to the normal omentum and by a second pedicle to some fixed point within the abdomen (Fig 2 e), or in the sac of a hernia (Fig 3, h). But if the area of adhesions to the distal fixed point is large the omentum is divided into three portions, a proximal normal portion, a central strangulated mass connected by one pedicle to the normal omentum and by a distal pedicle to a second likewise strangulated mass, which may be intra-abdominal (Fig 2, f) or intra-hernial (Fig 3, g). Several cases of this class are recorded.

Cases of the third class or complex torsion are more complicated in their mechanism, as the strangulation is produced by knotting or twisting of separated shreds of omentum about each other (Fig 4, k), or of one shred about the main omental mass (Fig 4, l). But few cases of this class are recorded. They may be either abdominal or hernial in type.

ETIOLOGY AND MECHANISM

The normal great omentum hangs down like an apron in front of the intestines and is attached by a broad base to the transverse colon and stomach, the distal extremity hanging free within the abdominal cavity subject to movements imparted to it from the intestines and other abdominal organs and to influences from without, with probably also an independent movement of its own.

Should the free extremity of the omentum become

Fig 3—Torsio omentalis intra hernialis et intra abdominalis

thickened or matted into a mass or ball we would have conditions favorable to a torsion, analogous to those of a triangular piece of cloth attached by its base to a fixed point with a weight hanging from its apex (Fig 2, c). If the free extremity should become adherent to any fixed point, as so frequently occurs, we would have a condition analogous to a triangular cloth attached by its base and apex, each to a fixed point around which the intervening portion could rotate on its long axis (Fig 2, e). In this case there would be formed two pedicles and either one or two strangulated portions according as the attachment of the apex was over a large or small area (Fig 2, e and f, Fig 3, g and h).

The conditions necessary for the production of an omental torsion are, therefore, the formation of a mass of matted omentum at its free extremity or the formation of a second fixed point by adhesions of the free end to some other structure.

That a hernia is the most frequent factor in the production of these conditions is evidenced by the frequency with which its presence is mentioned in the reported cases. In but six of the fifty-four cases collected by Corner and Pinches¹² was the presence of a hernia deemed. Even in these cases doubt is thrown on the actual absence of a hernia by a recent observation of Rie-

del's¹³. In a young woman on whom he operated, with a diagnosis of acute appendicitis, an acute torsion of the omentum was discovered. There was no hernia demonstrable externally, but on carefully pulling up the omental mass the neck of a femoral hernia came into view. Further traction disengaged the tip of the omentum and it appeared in the form of a plump mass twisted once on its axis. In this case had the reduction of the hernia been accomplished before opening the abdomen or unconsciously during the operation, as could easily happen this case would have been reported as "no hernia." Riedel is inclined to believe, therefore, that this condition is frequently present in "no hernia" cases.

Inguinal hernia has been the variety most frequently present, but femoral, umbilical and ventral hernias are represented among the reported cases. I have been able to find mention of but one other case than my own of hernia in a laparotomy scar, that of Souligoux and Deschamps¹⁴. The great majority of the hernias are ancient, as one would expect, for matting and adhesions to occur. Although hernia is the cause of the vast majority of cases, the same conditions may undoubtedly be produced by other processes. The matting or balling of the free extremity may be produced by tumors or by inflammatory thickening.

Adhesion of the free end of the omentum may take place to any organ within the abdomen and torsion re-

Fig 4—Torsio omentalis complexa

sult. In Noble's case¹⁵ it was adherent to the fimbriated extremity of the fallopian tube, in Peck's case¹⁶ to the right ovary, in Wiener's case¹ to an appendix epiploica of the ascending colon and to the abdominal wall, and in Simon's second case¹⁸ it was adherent to an ovarian tumor. The complex torsion may be produced by hernia or by inflammatory changes, causing separation of the omentum into shreds, which become twisted or knotted.

SYMPTOMATOLOGY AND DIAGNOSIS

That the formation of a matted mass or ball of omentum is a necessary antecedent to the strangulation by torsion seems probable for it is otherwise difficult to account for the mechanism. It is, however, not until sufficient torsion has occurred to obstruct the return circulation that symptoms of strangulation appear. The presence of the omental mass may have been unnoticed, or its presence may have been known for some time as a solid tumor within the abdomen or within the sac of a hernia, without symptoms of strangulation having appeared. If the torsion takes place slowly, or if it is of

¹⁸ Münch. Med. Wochenschr. 1907 xlii

a degree sufficient only to cause slight obstruction to the return circulation, the symptoms will be of a mild character. If the torsion is intra-abdominal there may be only vague discomfort with or without ascites.

If the omental mass lies in part or as a whole within a hernial sac the symptoms will be those of a mildly strangulated hernia. In the vast majority of cases the onset has been sudden and the symptoms have been those of acute strangulation, differing in no wise from those of acute strangulation of the omentum in an epiplocele. If a part or the whole of the strangulated mass lies within the hernial sac the signs also are those of strangulated epiplocele. The presence of a strangulated mass within the abdomen also adds little if any to the symptom complex, and it is only the discovery of a tumor within the abdominal cavity which distinguishes the intra-abdominal and the combined hernial and abdominal from the purely hernial cases. In Rudolf's case¹⁰ only has a correct diagnosis been made before the operation. The most frequent diagnoses have been that of intestinal strangulation, appendicitis and peritonitis.

The only cases which admit of a probable diagnosis are those in which the presence of an old omental hernia, reducible with more or less difficulty, has called attention to the probability of a matting or balling of the omentum. If, then, symptoms of strangulation should appear a suspicion might be aroused of the real nature of the affection. If, in addition, the intrahernial mass is found to be directly continuous with a mass within the abdomen and more especially if the intrahernial mass is reducible without relief of the symptoms, a diagnosis of reasonable probability could be made.

When torsion of the omentum becomes more widely known as a possible cause of symptoms of strangulation and is considered as a possibility in every case in which the symptoms and signs point to intestinal or omental strangulation, a correct diagnosis before operation will be more frequently made.

PROGNOSIS

As the diagnosis has been made in but one case before operation, it is impossible to make any definite statement sustained by facts as to the mortality of this affection if left to itself. The degree of strangulation, the area of the strangulated mass, and its location, will determine the issue. That unaided recovery is possible, even in acute cases, would seem probable from what we know of strangulated epiplocele. Repeated attacks are recorded from which recovery has taken place, the nature of the attacks being unrecognized until a more severe one has led to operation, and the discovery of the probable cause of all previous symptoms. If the degree of strangulation is sufficient to cause gangrene of the omentum the probable result would be, and has been in several cases, peritonitis and death.

The results of treatment have been most satisfactory. As would be expected the cases of early operation have, without exception, recovered. As in all cases of strangulation of abdominal organs, the mortality depends on the stage of operative intervention.

TREATMENT

There can be but one treatment of this affection—early operation and removal of all omentum which shows signs of strangulation. Fortunately the necessity of early operation is apparent in most of the affections for which torsion of the omentum has been mistaken. In one

case, that of Eitel,⁶ the twisted omentum was unrolled and allowed to remain, but this plan, even if desirable, could be followed only in such an exceptional case as his.

EXAMPLES

I have selected from the collected reports, as far as possible, a type of each of the classes described, and a perusal of the abstracts may prove of interest.

CLASS 1—*Torsio Omentalis Intra Hernialis* (Obest)¹¹
Male, aged 35. A right inguinal hernia which had existed for twelve years became irreducible two days before the operation. A diagnosis was made of irreducible hernia. At operation the sac was found to contain an omental mass, connected by a pedicle leading through the inguinal rings to the normal omentum within the abdomen (Fig 1, a).

CLASS 2—(a) *Torsio Omentalis Intra Abdominalis Chronica*
As an example of the chronic form of this class, Eitel's case,⁶ I think, may be cited, although Corner and Pinches¹² exclude the case, claiming that torsion was not proved.

Male, aged 44, with great abdominal ascites. Three gallons of fluid withdrawn by tapping. Twenty four days later a second tapping withdrew two and one half gallons, and a tumor, which was soft, movable and painless, was discovered in the abdomen. At operation three days later a tumor was exposed consisting of omentum, "rolled inward and upward, producing constriction and obstruction to the return circulation, as evidenced by enormously dilated veins." The tumor was unravelled without difficulty, and the omentum spread out over the intestines. The enlarged veins disappeared and the omentum resumed a normal appearance. The other abdominal organs were normal.

That in this case the obstruction to circulation was due to torsion seems probable, and Eitel's neglect to use the word, I think, should not exclude his case. That the ascites was due to the constricted omental circulation certainly seems probable, as it did not return after unrolling the omentum.

(b) *Torsio Omentalis Intra Abdominalis Acuta*—Acute intra abdominal torsion of the omentum about one point only (Fig 2, c) is well illustrated by the case of Simon.¹³

TYPE 1—Male, aged 26. There was no hernia nor disposition to such, to which adhesions of the omentum could have occurred. The symptoms were such that a diagnosis of acute appendicitis was made. On opening the abdomen, one and one half liters of bloody fluid were found. The omentum was converted into a bluish black tumor, measuring 18 cm in length. It had but one pedicle, which was attached to the middle of the transverse colon. Resection was followed by recovery.

My own case is an example of this class, but of that variety in which a part of the strangulated mass is contained within a hernia sac (Fig 2, d).

The variety of acute intra-abdominal torsion in which twisting occurs about two separate points (Fig 2, e) is well illustrated by the case of Bayer.⁸

TYPE 2—A woman, aged 54, had a left inguinal hernia for fifteen years. Following an attack of coughing there was some pain in the hernia with the sensation of a body revolving within the sac. On the following day an operation was undertaken for strangulated hernia. There was found a mass of strangulated omentum within the abdomen, attached by a proximal twisted pedicle to the transverse colon, and by a distal twisted pedicle to the abdominal wall near the mouth of the sac, both pedicles being within the abdomen. A portion of the strangulated mass had been extruded into the hernial sac.

The case of Peck¹⁴ should probably also be included in this class, as the strangulated omental mass which lay wholly within the abdomen, was connected proximally to the transverse colon by a tightly-twisted pedicle and was adherent distally by old adhesions to the right ovary. Simply the presence of adhesions between the omental mass and neighboring organs is not suf-

sufficient to warrant the statement that torsion occurred about two points, but the presence of old adhesions makes it seem probable

CLASS 3—Torsio Omentalis Intra Abdominalis et Intra Hernialis As the presence of two pedicles, one in the abdomen and one within a hernial sac, is the distinguishing feature of this class, they are all examples of torsion about two separate points, but two types may be distinguished according as the distal pedicle lies between an intra abdominal omental mass and a second intrahernial mass (Fig 3, g), or stretches from a single intra abdominal mass, through the neck of a hernia to a fixed point within the sac (Fig 3, h) As an example of the first type the case of Audier²⁰ is typical

Type 1—A woman, aged 50, was operated on in *extremis* for a strangulated hernia A mass of gangrenous omentum was found in the hernial sac On enlarging the wound upward, this mass was found connected by a pedicle to a large mass, also strangulated, within the abdomen This large mass was in turn connected by a second pedicle to the transverse colon The gangrenous omentum was resected, but the patient died in collapse

The second type in which but one strangulated mass is found (Fig 3, h) is well illustrated by Nordmann's second case²⁰

Type 2—A man with a right congenital inguinal hernia previously reducible developed symptoms of strangulation In the abdomen bloody serum was found and the omentum was adherent and thickened The omental mass was twisted close to the transverse colon above, and a second pedicle, also twisted, led through the neck of the hernia to the testicle where it was adherent Resection was followed by recovery

Complex Torsion—The examples of this variety are few, but the case of Hertz and Bender²¹ will illustrate one form of complex torsion (Fig 4, k)

A left inguinal hernia which had been irreducible for some time, revealed on operation that the lower extremity of the omentum had become separated into two parts, which had become twisted at their bases about each other, so tightly as to cause obstruction to the circulation

When a description of the condition known as torsion of the omentum is included in the text-books on surgery and its mechanism and symptomatology become more widely known I believe it will prove to be a much more frequent affection than the reports indicate

Although the number of reported cases is now above sixty, the publishing of future cases will be of value In order to aid in the classification of cases future reports should be exact in their description of the conditions present. The location of the point or points of torsion should be explicitly stated and the location of the strangulated mass or masses The presence of old adhesions of the omentum and their bearing on the mechanism should be noted The presence or absence of a hernia should always be stated, and if no hernia is apparent, careful search of the abdomen should be made at the operation for hidden hernial sacs

If the possibility of torsion of the omentum be borne in mind in every case in which the symptoms point to strangulation of some abdominal organ, a correct diagnosis before operation will become more frequent than has hitherto been the case

Clinical Notes

ACUTE PURULENT MYOSITIS*

A. O. SQUIER, M.D.
SPRINGFIELD, MASS

Patient—Dr. L. P., aged 39, consulted me at my office about 6 p. m., May 13, 1905

History—The patient stated the day previously he had changed the dressings of a child on whom a tracheotomy had been done for relief of tracheal obstruction due to the pressure of a purulent collection in the adjacent tissues While doing this his patient coughed and ejected a quantity of the tracheal contents, particles of which he was conscious were projected into his face, nose and throat. No immediate ill effects were observed, but about noon of the following day he began to have chilly sensations, headache and some pharyngeal soreness The chilliness increased steadily during the afternoon, until at the time I saw him he was having a severe rigor with chattering of the teeth and general muscular quivering Temperature, 102 F., pulse, 106, respirations, 24 He complained of severe headache, anorexia and tendency to vomit. He was at once ordered to bed During the succeeding twelve hours he had a short, dry, hacking cough and intense frontal and occipital headache and severe backache His tongue was heavily coated and he complained of discomfort in right chest He was nauseated several times during the night, very restless until 1:30 a. m., then dozed occasionally He had a slight epistaxis at 2 a. m. and chilly sensations during the night On the morning of May 14 he felt much improved and was inclined to consider his illness not serious He requested to see the daily papers and proposed getting dressed and about later in the day Temperature, 99.2 F., pulse, 72, respirations, 20 This improved condition continued until after 3 p. m., at which time the records were as stated He had slept at intervals during the day About 5 p. m. he began to have chilly sensations and complained of intense muscular pain in left arm and left chest, and of severe diffuse headache and backache At 7:45 p. m. his temperature was 103.1, pulse, 112, and respirations, 26 At 10:30 p. m., temperature was 104 F., pulse, 126, and respirations, 26 He slept none during that night, skin was hot and dry, had frequent nausea, and his fingers and toes were cyanotic at intervals He was bathed frequently and liquid nourishment was given him His urine for twenty-four hours was 10 ounces and contained a large quantity of albumin and many granular and hyaline casts

From 6 p. m., May 14, until after noon May 17 his temperature ranged from 103.2 F. to 104.4 F. continuously There was no regular diurnal variation, it sometimes being high in forenoon, again in afternoon or at midday or midnight Hot sponge baths induced free perspiration for short periods On May 15 he had five free liquid dejections following the use of elaterium The pulse range during this time was from 106 to 120, and his respiratory rate 20 to 26 During the night of May 16 he coughed frequently, was delirious at times and had rather profuse epistaxis at 10 p. m. Slept one and one half hours during the night

On May 17 he complained of severe pain in region of left pectoral muscle, had persistent, dry, hacking cough, but no expectoration, suffered from intense postocular and occipital headache Light annoyed him He had a moderate epistaxis three times during the forenoon Was delirious at frequent intervals during the day and perspired freely in the evening

On May 18 at 9 a. m. consultation was held with Drs. J. H. Musser, Weiser, Keefe, Guild and Weston Patient's temperature was 103.2 F., pulse, 104 and respirations, 25 He had slept but about twenty minutes during the night A most thorough examination of the chest was made, but no abnormal pulmonary or cardiac condition was demonstrable The left pectoral muscle was somewhat indurated and exquisitely tender on palpation Needle exploration for pus was negative The subsequent progress of the case demonstrated the insufficiency of this method for determining the presence of pu

Anesthetize Patients on Operating Table—Dr. J. T. Gwaltney, New York, states that patients should be anesthetized on the operating table, thus avoiding the lifting and jolting otherwise necessary He declares that there is no reason why every operating table should not be fitted with wheels thus making it possible to anesthetize the patient in an adjoining room

* Read at regular meeting of Hampden Medical Society Oct. 17, 1905

Diagnosis—Acute myositis, infective, with acute nephritis, probably also infective. The infective agent probably the pneumococcus, gippe bacillus or staphylococcus. In the endeavor to determine the infective agent careful bacteriologic examination was made by Dr. Guild of both the nasal and buccal discharges, but without demonstrating the pneumococcus. The patient was delirious the greater part of the day.

May 19 Patient slept about eight and one half hours (induced). Complained of aching in all parts of body, with particular soreness of left chest on coughing or deep inspiration. Temperature, 102.6 F at noon, 100.2 F at 6 p. m., pulse ranged from 104 to 98.

May 20 Soreness in left chest, stiffness and pain in cervical region. Temperature (high), 102.6 F at 3 a. m., (low), 101.2 F at 3 p. m., pulse, 110 to 96, respirations, 44 at 9 p. m., 26 at noon.

May 21, 22 and 23 Temperature ranged from 102 F to 99.6 F, pulse from 104 to 88, and respirations from 44 to 26. Slept most of the time. Had to be awakened for nourishment and medicines. Complained of general pains throughout body, and of an annoying, short, dry, hacking cough most of the time when awake, and of severe headache.

May 24 Headache continued and he complained of vertigo of subjective type, and of frequent attacks of faintness and malaise. His skin was cool, moist and clammy. Temperature, 102 F to 99 F, pulse from 110 to 90, and respirations from 32 to 26. During this time there was exquisite tenderness, marked redness and a tense, indurated condition in the left pectoral region. Sometimes deep palpation would indicate that there might be fluid deeply seated, again this would not be demonstrable, but the muscles felt hard and tensely drawn against the chest wall. Pain was constant in the left pectoral muscles and left arm. There was no voluntary movement of the arm because of increased pain if such movement was attempted. The forearm was flexed on the arm most of the time, this position affording the greatest degree of comfort. The arm could be moved only about two inches laterally without causing extreme pain.

May 25 to June 3 inclusive Patient perspired freely and continuously, and the pain in his left arm was very severe and continuous. He felt extremely weak and exhausted. Had several large, loose dejections with sharp, griping pain in bowels every day. He attributed this to the milk (which had been peptonized), and for three days milk was discontinued and other forms of nourishment substituted—barley, egg albumin, chicken broth and meat powder. The dejections were apparently well digested only two containing undigested particles. Headache was constant. He perspired freely during the night. Slept on an average eight hours every night, and from five to eight hours during the day. Had severe pain in left arm and occasional chilly sensations. There was a distressing tendency to cough. His face was very red at intervals, being cyanotic about the nose and ears. Had more pain in arm during the last two days and less in chest wall.

On June 2 about 4 p. m. he complained of feeling cold and of having increased pain. The pain in the pectoral region was described as of a deep boring, burning character. Some soreness of throat with constant headache and increased hebetude. Temperature ranged from 102.6 F to 98.6 F, during most of this time being from 100 F to 101 F. Pulse was of good volume and from 114 to 92, the greater part of the time being between 100 and 110. Respirations were from 30 to 24. For several days there had been an increasing difference of opinion between the attending physicians as to the demand for surgical intervention, and on June 3 it was determined to summon Dr. J. B. Deaver in consultation. He saw the patient at 8 a. m. June 4. It was then decided that the patient should be removed from his hotel, where he had been from the beginning of his illness to the hospital. This was done.

Operation—At 9 a. m. June 4, operation was done by Dr. Deaver. An incision was made from near the left coracoid process diagonally downward across the chest, following approximately, the lower border of the pectoralis major muscle to a point near the lower end of the sternum. About eight ounces of thick purulent material was evacuated. The muscle was considerably disorganized but as remarked by Dr. Deaver

at the time, apparently not sufficiently to preclude possible restoration to comparative usefulness. Numerous pus foci were present scattered through the body of the pectoral muscles. These were evacuated, the large pectoral muscle being lifted from the chest wall and all the exposed parts thoroughly cleansed. Four counter openings were made through the skin along the line of the clavicle at the upper border of the cavity, through which large rubber drainage tubes were passed, emerging through the long incision below. The wound was then packed with gauze and the patient returned to bed. Previous to the operation the temperature was 99.8 F, the pulse 106, and the respiration 24.

Postoperative History—Patient recovered consciousness at 10.20 a. m. The skin was cold and covered with a profuse clammy perspiration. At noon his temperature was 97.6 F, pulse 114, and respirations 20. He slept at intervals during the day. Complained of chilly sensations about 5 p. m. There was considerable serous oozing from the wound. At 9 p. m. his temperature was 103.8 F, pulse 140, and respirations 38. He perspired freely all night. Felt weak, but had no pain in arm or chest, and slept eight hours.

June 5 to 9 inclusive At 6 a. m. of June 5 his temperature was 100.4 F, pulse 140, and respirations 34. At 6 p. m. temperature 102.1, pulse 138, and respirations 28. During the following days the diseased area was thoroughly irrigated twice daily with antiseptic solutions and packed with plain gauze. Temperature ranged from normal in the morning to 101.6 F at night. Pulse from June 6, two days after operation, to June 10, from 98 to 110. Respirations, 24 to 30. To the date of the surgical intervention, mental depression had been a marked feature. Following the surgical measures the mental attitude changed decidedly and the patient was bright and cheerful.

June 10 Complained of more pain in left shoulder and chest, and also of great exhaustion. Had occasional chills. Temperature ranged from normal to 102 F, pulse weaker, 116 to 128, respirations, 24 to 28.

June 11 Pain through left chest, shoulder and arm increased. Increased discharge of pus and perspired profusely, especially when asleep.

June 12 Temperature from normal to 101.2, pulse, 120 to 138, respirations, 24 to 28. This condition continued with little if any change until June 17, the patient feeling very weak and exhausted and having severe pain in left arm, shoulder and chest. Temperature, from 100 F to 103 F (latter at 6 p. m. both 16th and 17th), pulse, 126 to 148, respirations, 26 to 30.

Second Operation—June 18—At 9 a. m. temperature was 99.6, pulse 126, and respirations 26. At 6 p. m., temperature 102.6 F, pulse 124, and respirations 28. At 8 p. m., operation by Dr. Deaver, consisting of complete extirpation of the left major and minor pectoral muscles with clearing of the axillary space which was filled with disorganized, broken down tissue. The pectoral muscles consisted of softened, infiltrated debris, with numerous pockets of pus. The denuded surface was swabbed with pure carbolic acid, followed immediately with alcohol, and the wound was then packed with gauze saturated with alcohol. The patient was returned to bed at 8.55 p. m. in a state of collapse with no perceptible radial pulse, surface of body cold and bathed in perspiration. At 9.30 p. m. pulse was 200, at 10 p. m., 210, at 11, 180, at 12, 200, at 1 a. m., 220. Died at 1.30 a. m. without having recovered consciousness. The improvement in the pulse shortly after 10 a. m. followed the intravenous introduction of 24 ounces of physiologic salt solution.

Urinalyses—The first quantitative analysis of the urine was made May 16 and contained 17 per cent (by volume) of albumin, numerous other coarse, dark, granular, medium sized casts, some hyaline casts and a few epithelial cells. Urea 10 grains to the ounce.

May 19 Albumin, 4.5 per cent (by volume).

May 26 Albumin, 1.75 per cent (by volume). During this period the chlorids fluctuated between 1 and 2 per cent. Urea normal or slightly below.

May 30 There remained but a trace of albumin, chlorids

7 per cent, and urea $6\frac{1}{2}$ grains per ounce. There were found three medium sized hyaline casts.

June 7 Albumin entirely gone, urea 6 grains to ounce, chlorids 9 per cent. The twenty four hour quantity fluctuated between 50 and 100 ounces, averaging 70 to 80 ounces.

Bacteriologic Examinations—May 15. Vidal test for typhoid, negative. On June 1 a blood examination showed the leucocyte count 20,650 per mm, increase confined to the polymorphonuclear leucocytes. It was an inflammatory leucocytosis, probably septic, not enough to warrant a diagnosis of pus formation. On June 5 a bacteriologic examination of specimens of pus taken from swabs of diseased surfaces at time of operation on previous day showed only the staphylococcus pyogenes aureus.

Dietetic Treatment—It was realized from the outset that the patient was suffering from a complication of diseases of a most serious nature. The attempt was made, therefore, to secure the assimilation of a sufficient variety and quantity of food to fully support the vital forces. To do this without overworking the renal organs added to the difficulties. The patient was supplied with, and perfectly assimilated from 2,000 to 4,000 calories of mixed foodstuffs during each twenty-four hours of his sickness. During the entire period he had but two dejections containing undigested particles in sufficient quantity to be determinable by macroscopic examination. He was so well nourished as to occasion approving comment of the professional friends who saw him.

Medicinal Treatment—The first day he had, in divided doses two grains of calomel, which acted mildly. On the second day he had one grain of elaterium, divided in eight doses. This was followed by free watery dejections with immediate relief from uremic symptoms. On the fourth day he had one dose (by rectum) of 20 grains of chloral hydrate and 60 grains sodium bromid, which was followed by several hours of refreshing sleep. At this time and continuing for several days he had 20 grains of potassium citrate every four hours, alternating with one drop doses of a 1 per cent solution of glonoine. From June 3 to June 10 he had no drugs. From this date until the end he had strychnin sulphate, $1/40$ to $1/30$ grain hypodermatically at three and four hour intervals.

The surgical conditions and treatment have been given in detail in the history of the case.

THE BLOCKING OF AURICULAR EXTRASYSTOLES

ALBION WALTER HEWLETT, M.D.
SAN FRANCISCO

The newer methods of analyzing the venous pulse have enabled us to differentiate clinically a number of forms of cardiac arrhythmia that could not otherwise be properly classified. So far as I am aware, arrhythmias due to a blocking of extrasystoles on their passage from the auricles to the ventricles have not been described. I am able to report such a case here through the kindness of Dr. T. W. Huntington.

Patient—P. C. clergyman aged 56, entered the Lane Hospital for operation on a left inguinal hernia.

History—His family history was excellent and his past history contained little of note. He had been twice poisoned by eating mussels, the last time five years ago, but had never had a severe illness. He habitually drank a cup of coffee in the morning, a cup of tea at noon and an occasional glass of wine at meals. He did not use tobacco. He first noticed some irregularity of the heart three months previously. He did not know what brought it on nor what made it worse and was conscious of his heart action only when considerably excited. He had no shortness of breath on exertion, no swelling of the feet, no attacks of dizziness, no cough, etc.

Examination—This showed a rather nervous, fairly well nourished man. The right pupil was slightly larger than the left, both reacted to light and on accommodation. Lungs abdominal, and reflexes were negative.

Heart and Vessels—The point of maximum impulse was in

the fifth intercostal space, 2 cm. outside of the mammary line and 12 cm. to the left of the median line. The area of cardiac dullness extended from the upper border of the third rib to 12 cm. to the left and 3 cm. to the right of the median line. The heart sounds were clear, the first being of a booming quality at the apex, the second at the pulmonary area was accentuated and reduplicated. The radial arteries were markedly thickened and contained irregular hard plates. The temporal arteries were also thickened and tortuous. Pulse. The rhythm was interrupted at times by small premature beats, followed by longer compensatory pauses, at other times there was simply a pause in the regular succession of beats without any palpable premature pulse. These pauses were sometimes so frequent as to produce for a short time a slow and perfectly regular rhythm (Fig. 2). One might have suspected that he was dealing with an ordinary case of extrasystoles, some of which produced a radial pulse, while others did not. Auscultation over the apex, however, showed complete silence during most of the interval when no extra pulse was felt, whereas, as is well known, extrasystoles affecting the ventricles invariably give rise to a well marked first sound.

Sphygmography—In Figure 1 are seen tracings of the radial pulse, the apex beat, and the jugular pulse during a comparatively normal period. The duration of the normal pulse interval is about 0.85 second. The jugular tracing shows the three characteristic waves *a*, due to the contraction of the auricle, *c*, the transmitted carotid pulse, and *v*, following the contraction of the ventricle. The regular

Fig. 1.—Normal pulse rate interrupted at *x* by an extrasystole which starts in the auricles and spreads to the ventricles.

rhythm is interrupted by an extrasystole at *x*. This extrasystole shows slightly on the rather poor apex tracing, and slightly also on the radial tracing. On the jugular tracing it is indicated by an unusually high wave *a*, which begins a little earlier than the *v* wave, which should follow the preceding normal systole. The early occurrence of this wave and its height lead us to believe that it is due, at least in part, to a premature auricular contraction, and possibly in part to the *v* wave from the preceding normal systole. The carotid pulse following this extra auricular contraction is so small as not to be visible on the tracing from the neck, but the radial tracing shows that a small extra pulse was present. The apex tracing and the occurrence of a *v* wave on the jugular tracing likewise bear witness to the occurrence of an extrasystole of the ventricle. This tracing shows, therefore, a normal pulse rhythm interrupted at one point by an extrasystole. The latter originates in the auricles and spreads thence to the ventricles.

The radial pulse in Figure 2 might lead one to suspect a slow and regular heart action were it not that the apex tracing and a closer inspection of the radial tracing also demonstrate the presence of extrasystoles, *x*. It is possible to have ventricular extrasystoles interpolated between the normal beats of a slowly beating heart without there being any compensatory pauses. On such an assumption the normal pulse interval in this tracing would be 1.5 seconds, but from Figure 1, which is a continuation of Figure 2, on the same piece of paper, we have

already learned that the normal interval is 0.85 second. From a comparison with this earlier tracing, it also becomes apparent that those extrasystoles of Figure 2 involving the ventricles are exactly the same as the solitary extrasystole of Figure 1. They all originate in the auricles and spread thence to the ventricles. In two places on Figure 2, however, no extra ventricular contractions are interposed between the normal beats. This appears not only from an inspection of the apex tracing, but from the complete absence of heart sounds previously referred to. A study of the jugular pulse shows the cause of this absence. The ordinary extrasystole in this patient shows itself on the jugular pulse by a well marked a' wave, due to the premature contraction of the auricle, and also by the c and v' waves, due to the contraction of the ventricles. During these intermissions, however, the high a' wave alone appears. The auricles contract prematurely, but no contraction of the ventricles follows.

The reason why the ventricle fails to contract may be studied in Figure 3, which by a fortunate coincidence shows on a rapidly moving paper the three main features of this pulse, viz. The normal pulse, the extrasystole crossing to the ventricle, and the extrasystole that affects the auricles only. The interval between any a wave (contraction of the auricle) and the succeeding c wave (carotid pulse), the ac interval, as it is called, has been taken by Mackenzie to measure the rate of transmission of the cardiac contraction wave from the auricles to the ventricles. Its normal duration is 0.2 second or less, and if it

Fig. 2—Each normal pulse is followed by an auricular extrasystole. In those marked x the extrasystole spreads from the auricles to the ventricle. In the remaining two the contraction wave does not affect the ventricles.

be longer than this, Mackenzie considers that the conductivity across the His bundle is impaired. The ac interval for the normal beats in my patient was 0.18 second, or about normal. The ac interval for the extrasystoles on the other hand was 0.35 second, a very considerable prolongation (0.17 second beyond his normal), yet the prolongation here was due only in part to a loss of conductivity. A comparison of the apex and jugular tracings shows that the interval between the beginning of the a wave on the jugular tracing and the beginning of the ventricular contraction on the apex tracing is 0.13 second in the normal beat and 0.21 second in the extrasystole, a lengthening of 0.08 second. The remainder of the lengthening of the ac interval is due to the fact that an abnormally long time elapses between the beginning of the ventricular contraction and the beginning of the carotid pulse (prolongation of the period of ventricular tension). Thus in Figure 3, the interval between the beginning of the ventricular systole and the beginning of the normal carotid pulse is 0.05 second, while the same interval for the extrasystole is 0.14 second, a difference of 0.09 second. At least two factors tend to lengthen the period of tension both of which depend on the early occurrence of the abnormal contraction. In the first place, the aortic pressure is highest just after any systole so that the earlier the succeeding contraction the longer it will take for the intraventricular pressure to reach such a height as to exceed the aortic pressure and

to open the semilunar valves. In the second place, the contractility of the ventricle is reduced after a systole and it seems reasonable to assume that a weakened ventricle should take a longer time than a rested one to produce a certain pressure.

How are we to explain the complete absence of certain ventricular contractions? Two possibilities present themselves. 1, A lack of conductivity from the auricles to the ventricles, 2, a lack of contractility on the part of the ventricles. We have just seen that where the ventricles take part in the extrasystoles both conductivity and contractility are diminished. The diminution of conductivity is apparent from the lengthening of the interval between the contraction of the auricles and the contraction of the ventricles. The diminution of contractility is evidenced by the prolongation of the period of tension. A still further reduction of either of these might lead to a falling out of the ventricular systole, but it is difficult to decide which is actually most at fault in this patient. One fact mitigates against its being a lack of contractility. In the many times I listened to the irregular heart action I have never heard an extrasystolic first sound that was not followed by a second sound, which means that the ventricular contractions when present, were always of sufficient force to send blood into the aorta or pulmonary artery. Had the falling out of the extrasystoles been due to a lack of contractility we should have expected to find transition systoles of such force that, although the ventricle contracted, the

Fig. 3—Record on a rapidly moving piece of a paper. First a normal contraction followed by an extra auricular contraction, but not ventricular contraction; second a normal contraction followed by an ordinary auricular extrasystole; third a normal pulse without an extrasystole.

semilunar valves were not opened. The apparent absence of such extrasystoles causes us to favor the view that the falling out of ventricular contractions was due, not to a lack of contractility, but to a failure of impulses to cross the auriculoventricular junction.

The slowing or failure of the conduction during the extrasystoles is due to the occurrence of the latter so immediately after the preceding normal beats. The interval was not sufficiently long for the conductivity of the His bundle to return to its normal level. A similar observation has been made on hearts whose conductivity was but slightly diminished. In such hearts every contraction wave may pass from the auricles to the ventricles so long as the rate is a slow one, but if the rate becomes accelerated one or more waves are blocked at the auriculoventricular junction.

Syncope in Biliary Colic—Maggard, in the *Journal of the Kansas Medical Society*, states that the syncope which some times attends biliary colic is best treated by atropin, strychnin, normal salt solution and brandy. Ether is a valuable heart stimulant and should be injected deeply when given hypodermatically in order to prevent the severe pain which it produces when injected superficially.

AN IMPROVED AND ACCURATE METHOD OF LOCATING FOREIGN BODIES WITH THE ROENTGEN RAY *

ROBERT CAROTHERS, M.D.
CINCINNATI.

There are living to-day many veterans of the Civil War who have carried bullets within their bodies all

or increase neurasthenic symptoms and then the foreign body must come out

Asepsis is of prime importance in foreign body surgery, as also is surgical experience. It is no work for the novice. I have seen two failures by young men who, after radiograms had been made, viewed the work from a light-hearted standpoint, but in the end were glad to have assistance. Even under the most favorable

circumstances it is not always easy work, leading one not infrequently, into dangerous waters and sometimes trying to the limit one's patience. The easy cases in dexterous hands are misleading, and that coolness and equipoise a surgeon acquires from experience is much to be desired in this branch of surgery.

If the field of operation can be made dry with tourniquet or otherwise it is a decided advantage. Whatever else may be said, the most important requisite is a definite idea of the location of the foreign body. The Roentgen ray has been of untold value in supplying this requirement.

Stereoscopy, as applied to skiagraphy, called stereoskiagraphy, is the most improved method and would seem to give the most accurate location of a foreign body. The object of this paper is really to demonstrate the stereoscope. This

Fig. 1.—Diagram showing method of obtaining stereoskiagram. A bullet or foreign body. B bone. C plate for exposure.

these years and who have experienced little or no discomfort from them. But while a foreign body within the anatomy is not always a menace to good health and it does not become necessary and imperative that it should be removed, it is undoubtedly true that foreign bodies do at times cause trouble that calls for their removal. In these days of neurasthenia it becomes, at times imperative to remove a foreign body for the relief of neurasthenia, although it must be admitted that such removal does not always relieve the condition. Since the introduction of the Roentgen ray this reason for removal is on the increase. An individual who is the recipient of a foreign body does not go far before some one either on solicitation or otherwise, makes a radiogram of the part which in many instances, is known to either excite

idea has been worked up by many radiographers in different parts of the country independent of each other therefore no one can claim unchallenged pri-

* Read before the Southern Surgical and Gynecological Association, Baltimore, Dec. 10, 1906.

ority The instrument shown in the illustration was designed and made by Mr. Kelley of the Kelley-Koett Manufacturing Co., and to him I am indebted for his mechanical skill in working out crude ideas. The ordinary Roentgen ray plate looks flat. The stereoscope gives a perspective view much as if the parts (bone and bullet) were before one.

Two separate plates are made of the same part without changing in the least the position of the part skia-graphed, which is placed on the compression diaphragm table on a hollow board or plate holder with a metallic bottom, so that the rays can be partially obstructed, and in this way one plate can be removed and a second supplied. The compression diaphragm is discarded and replaced by a hollow, double-inclined plane or platform at an angle of 160 degrees. With a plumb-bob the apex of the double-inclined plane is centered through the center of the part to be skia-graphed on to the center of the plate. The plates are made with the tube in the tube holder placed eighteen inches above the plate and one and three-eighths inches to either side of this central point so that they are made from points two and three-quarter inches separated from each other, corresponding to the distance between the human eyes.

The developed plates are placed in highly-illuminated boxes facing each other and are from them reflected into two small looking-glasses which are placed at a right

Fig. 3—The stereoscope shown in Fig. 2 enlarged

angle to each other with the apex of the angle placed between the eyes of the observer in the stereoscope. One now looks into the two looking-glasses, each eye in a separate glass sees a separate plate, then by adjusting the plates and the stereoscope to get an exact focus the two plates are made to look as one, giving a perspective view. This method is of especial value in locating foreign bodies in the spine, thorax and abdomen where it is impossible to get a plate, which is not flat, by any other method.

THE TREATMENT OF ABSCESES BY PUNCTURE AND DISINFECTION WITHOUT INCISION AND DRAINAGE

DR. WITT STETTEN, M.D.

Assistant Surgeon German and Mount Sinai Dispensaries
NEW YORK CITY

Stimulated by the results of Bier¹ and Klapp² with suction and hyperemia and of Lennander³ with his carbolic-alcohol method I have been led to attempt

a conservative treatment of localized suppurations without elaborate apparatus on the one hand and without incision and drainage on the other. The plan I followed is not a new one. It is simply a modification of older methods with a newer application. What Scott Helm,⁴ Hayden⁵ and others tried with buboes I modified and extended to almost every form of acute external abscess. The object was to avoid mutilating scars and protracted convalescence from extensive incisions and long-continued drainage. Briefly stated, the method is as follows:

1. After careful disinfection of the skin and under infiltration anesthesia of the most dependent portion of the abscess, the abscess is punctured with a large trocar or a pointed scalpel and the pus is gently expressed. This is superior to aspiration.

2. The cavity is then thoroughly irrigated through the trocar, which fits an ordinary 10 c.c. syringe, with a 1-1000 corrosive sublimate solution. This can be used with impunity in large quantities, as the abscess well does not absorb. I have found this strength to be the most satisfactory.

3. The remnants of the corrosive sublimate solution are carefully expressed and the abscess cavity is partly distended with a 5 to 10 per cent iodoform glycerin. A moist dressing with a firm pressure bandage is then applied.

In other words, the acute abscess is converted into a chronic one by more or less thorough disinfection and treated according to the principles originally laid down by Henle⁶ for the management of cold abscesses.

Up to date I have treated forty-five cases of every degree and variety with rather astonishing results. Most of them were cured without scarring in four or five days. Turbid serum oozes from the puncture wound for a day or two, all signs of acute inflammation subside and the walls of the abscess cavity agglutinate. Occasionally an induration persists for about a week, but eventually this entirely disappears. Sometimes sero-pus or serum reaccumulates, but expression, or if need be, redisinfection and reinjection remedies this. Rarely is a third treatment necessary.

Although there were never any unfavorable complications, abscesses of caseous tuberculous glands did not yield well to this treatment. These generally required a secondary curetting but were none the worse for the preliminary conservative therapy. There were four of this class in my series. All the other cases, whether of streptococcus or staphylococcus origin, particularly mammary and cervical abscesses, ran a very smooth course. The method is somewhat painful, but perfected technic will in a great measure dispose of this disadvantage. This treatment is not offered as a panacea for all acute abscesses but I am convinced of its indications and think it worthy of trial. It is not suggested as a revolutionary measure, but the results justify the opinion that incision and drainage have been practiced hitherto in the treatment of circumscribed pus formation with unnecessary and indiscriminate ruthlessness and severity.

I am indebted to Dr. Charles Goodman, in whose department of the Mt. Sinai Dispensary I carried out my treatment for the opportunity to give my theory a practical test.

ACUTE FRONTAL SINUSITIS—HARRIS

AN IMPROVED ADJUSTABLE ELECTRIC LIGHT STAND FOR OPERATING ROOMS

GILBERT ROYCE, B.A., M.B.
Formerly House Surgeon to the Eye and Ear Departments of the
New York Eye and Ear Infirmary
TORONTO

A feature of this standard is its universal adjustability. The whole stand can be rotated on its base. The height of the lamp can be regulated by the inner tube of the upright. The extension arm can be shortened or lengthened, tilted up or down or shortened and used vertically.

The standard consists of a heavy tripod base mounted on rubber-tired castors. Attached to this is an upright piece consisting of two tubes, one telescoping in the other, the movement of the inner tube being controlled

by a thumb screw. At the top of the inner tube a slot engages a U-shaped bracket, which can be tilted up or down and is retained in position by a winged screw. A short tube is brazed into the ends of the bracket. The upright piece of an ordinary goose-neck electric light stand is pushed through the tube in the bracket, where it can be clamped if necessary. The flexible part of this horizontal arm is of sufficient length (eight inches) to enable one to turn the light in any desired direction.

The lamp itself is a spiral filament stereopticon of 24 candle-power with no frosting and is shaded by an aluminum reflector so fastened as to allow of its being turned about the lamp in directing the light toward any side.

This apparatus has been found especially useful in mastoid work, for which, indeed, it was originally intended. The stand is placed behind the anesthetist and the horizontal arm, covered with sterilized towels is stretched forward over the patient, where the light, with the aid of one hand only, can be instantly and easily adjusted to illuminate the operative field or turned up toward the head-mirror of the operator. This appliance has been in use in the New York Eye and Ear Infirmary for the past year, and has given satisfaction. It is manufactured by the Hospital Supply Company of New York.

12 Carlton Street

ACUTE FRONTAL SINUSITIS

C. M. HARRIS, M.D.

Ophthalmologist to the Conemaugh Valley Memorial Hospital
JOHNSTOWN, PA.

Although writers frequently refer to ocular phenomena occurring as complications or symptoms of disease of the accessory cavities of the nose, I report this case in order to emphasize the importance of differential diagnosis and to illustrate the fallacy of too strictly limiting one's observation to the organ which exhibits the more pronounced symptoms.

History—A minister, aged 39, gave a history of good general health except for a chronic rhinitis of moderate degree. He had worn glasses during the past sixteen years. The latest pair proved to be lenses for the correction of simple myopia. I later found a marked degree of compound myopic astigmatism, which being corrected, greatly improved the vision. The patient had always been singularly free from the usual symptoms of eyestrain, seeking glasses only as a means of improving vision. In the latter part of the winter of 1897 he contracted a "cold" which was followed by excruciating pain at the root of the nose on the right side, extending outward along the supraorbital region and upward toward the vertex. The right eye was painful and sensitive to light. He consulted an ophthalmologist in the city where he then lived who pronounced it "optic nerve inflammation" and proceeded to treat the eyes. After a week of almost unbearable pain, a discharge of greenish pus appeared in the right naris and relief was prompt. Almost four years later after moving to another state, a similar attack developed. In spite of the previous history, another specialist treated the eye without so much as examining the nasal cavities. Another week of suffering, a flow of pus, and it terminated as before. In February of this year I saw him for the first time. He related his history and stated that he had recently been suffering from a "cold." For two days past excruciating pain in the right inner supraorbital and frontal regions and right eye had prevailed.

Examination—Light pressure over the eye and frontal sinus could hardly be borne. The eye was also exceedingly sensitive to light. The vision on comparison with the fellow eye, and with test after recovery, was about what one would expect in neglected myopia with astigmatism. The fundus appearance can be described in the same way. The left nasal passage was negative except for a moderate rhinitis. The right side, however, presented more rhinitis, and the middle turbinate was turged and had a glazed appearance.

Treatment—After application of adrenalin and cocaine an attempt was made to probe the frontal duct but it proved futile. An alkaline wash and an adrenalin spray were prescribed for nasal application. Acetanilid compound was given for pain, and atropin for its effect on the mucous membrane. He returned next day, reporting slight relief. Another attempt at probing proved successful. A small amount of pus appeared and relief was almost immediate. The turgidity of the middle turbinate and the flow of pus continued for about ten days. Absolutely no subjective symptoms have since been present.

APPENDICITIS AND ANGINA

According to Kretz,¹ acute phlegmonous appendicitis may be associated with acute tonsillitis, and in these cases streptococci occur as the predominating organism in the appendix, in the peritoneal exudate, and in the tonsils.

These conclusions are based on observations made after death, in cases in which the conditions were favorable for satisfactory study and all which occurred in young persons without previous attacks. The changes in the tonsils are marked. There is great swelling, pus oozes from the crypts on slight pressure, the tissue is succulent and there is edema of the surrounding structures; there is also swelling of the cervical lymph glands. Microscopically, in addition to the ordinary inflammatory changes, the tonsils show thrombosis of the lymph vessels and small fibrinous thrombi in the veins, but without purulent softening. In the cervical lymph nodes there may be large masses of cocci in the subcapsular sinuses and fibrin mixed with leucocytes and cocci in the central and efferent lymph vessels. So far as the changes in the appendix are concerned, they indicate that the process begins in the follicular tissue, whence it may extend to the peritoneum, either directly by continuity or in the form of lymphangitis in the mesentery.

As regards the route of the infection, assuming that the appendicitis is secondary to the tonsillitis, then the following possibilities must be considered. Pyogenic cocci may be pressed out of the tonsils in the act of swallowing and carried to the intestine, or the cocci may be transferred to the appendix by way of the blood. In favor of the latter as the more likely route speak the conditions already described in the tonsils and in the cervical lymph nodes, whence bacteria may pass directly into the blood (tonsillo-genous bacteriemia), and the conditions in the appendix itself and the adjacent parts of the intestinal tract, especially when death ensues early, indicate clearly that the inflammation begins about minute foci of necrosis and milary abscesses which correspond accurately in size and location to the lymphatic follicles, and which undoubtedly result from mycotic embolism, minute masses of cocci being found within the vessels in the center of the follicles. These

interesting follicular foci were observed by Kretz in the cecum and also in the otherwise normal ileum.

Naturally, Kretz supports the hypothesis already advanced by others that acute appendicitis in certain cases may be the result of a general infection which originates in a streptococcal tonsillitis and angina. The localization of the bacteria in the lymphatic apparatus of the intestine may be regarded as analogous to the localization that occurs in the bone marrow in acute osteomyelitis. In these cases (14) that serve as the basis of the work there was, as stated, no evidence of previous disease in the appendix, and the course of the disease was rapid and severe. Kretz points out that in certain cases of acute appendicitis of moderate severity there may be a history of attacks of tonsillitis shortly before the appendicitis. And in several cases of subacute appendicitis examined after death Kretz found marked changes of a somewhat chronic nature in the tonsils and enlargement of the cervical lymph nodes. He suggests that when appendicitis develops some time after an attack of angina it is less dangerous because the body has had time to arrange for its defense and is, therefore, less likely to be overwhelmed by the infection.

These observations again emphasize the importance of the tonsils in the etiology of various pyogenic infections. Kretz estimates that probably one-third of fatal pyogenic infections are associated with angina as an initial lesion, and he suggests, as others have done before him, that undoubtedly many acute, more or less transitory febrile conditions are in reality mild anginal or postanginal bacteriemias. He also points out that Semmelweis really was the first to announce clearly that many apparently heterogeneous inflammations—acute endocarditis, osteomyelitis and arthritis, acute pericarditis and acute inflammations of other serous membranes—really belong together by virtue of a common mode of origin, namely, acute angina. And we now know that all these manifestations of infection may result from localizations of the same infectious agents, the most important of which undoubtedly is the streptococcus, for the entrance of which the tonsils offer specially favorable opportunities. There is need of careful systematic clinical studies of the relation of tonsillar infections to acute appendicitis in order that the special characteristics of appendicitis as a manifestation of tonsillo-genous bacteriemia may become better known.

TYPHOID BACILLUS BEARERS AND THE PREVENTION OF TYPHOID FEVER

We have called attention to the investigations which have been carried on in the past few years, especially in Bavaria, bearing on the transmission of typhoid fever by apparently healthy individuals. Such cases have been shown, as the work has progressed, to be not infrequent. The Germans call them *Typhusbacillenträger*, but in the absence of precedent in our own language for the manufacture of such compound words we must call

them typhoid bacillus carriers or bearers. In a certain small district in Bavaria bacteriologic examinations of the discharges have shown over fifty infected persons. When we consider how difficult it is to trace epidemic outbreaks of typhoid to their source, the importance of such individuals becomes apparent. In the recent Scianton epidemic, for example, evidence showed plainly enough that a certain water supply was infected, but no record of a typhoid fever patient being in a situation to affect the supply was obtained after the most careful search. Doubtless some "bacillus bearer" who felt, and in fact, was, in good health carried the infection. Epidemics aside, small sporadic outbreaks of typhoid fever, such as occur in hospitals for the insane, and house outbreaks in remote country places, have usually been very difficult to follow to their source. Here, again the bacillus bearer doubtless plays a part. That this is sometimes the case is certain, as is shown by an instance cited by Dehler,¹ in which one bacillus bearer kept up a small outbreak.

The important question regarding the bacillus bearers is what is to be done to detect them and to prevent them from infecting others? So far as detection is concerned we know of no method now universally practicable. We may reach a stage in the development of preventive medicine when a typhoid patient will be quarantined, like a diphtheria patient, until he is free from bacilli. No physician who has done bacteriologic work among typhoid patients doubts that, under present conditions, hundreds of them are discharged from hospitals yearly bearing typhoid bacilli in their urine and stools. This takes no account of private patients who are less carefully followed bacteriologically. So long as such conditions continue, it seems a hopeless task to try to limit typhoid fever by our present method, viz., the disinfection of the urine and feces. If the bacilli disappeared as soon as convalescence was established, this would be all very well, but, as the work on bacillus bearers has shown, the typhoid germ may be present in the urine or stools for months. Doubtless the fecal infection is in many cases, as Dehler suggests, secondary to a gall-bladder infection. Doubtless, too, in some instances, as in a case quoted by this author, draining of the bile passages will cure the infection and render the individual harmless. Even supposing it were possible to detect all bacillus bearers, it would not be possible to keep them under the influence of hexamethylenamin or to force them to submit to having their bile passages drained.

Shall we ever be able then, to limit the ravages of typhoid fever? Certainly there is no excuse for outbreaks of the disease due to contaminated water supplies. The water company which permits conditions which allow of wholesale water contamination should be heavily mulcted by means of damage suits. It is doubtful that we shall be able to prevent sporadic crises of typhoid fever by educating the public in cleanliness. That it can almost

be done under military discipline the Japanese have shown us, but that it can be done under the circumstances of every-day life is to say the least, extremely dubious. There we are dealing not with trained men under discipline, but with the ignorant, the shiftless and those of immature years unable to realize the meaning of preventive measures. It almost looks as though the stamping out of typhoid fever must be accomplished by some other means than by preventing the entrance of the typhoid bacillus into the human economy.

What other means of stamping out the disease do we possess? At present it would seem as though our greatest hope lay in preventive inoculation. Originated by the English army surgeons, its use has recently been extended to the German army, and the statistics of Eichholtz² seems to confirm the view that it is a valuable procedure. This author's figures are small, but like the recent English figures, they show that inoculated soldiers are less liable to the disease, and when attacked show a much smaller mortality, much fewer severe complications, a shorter course and a milder run of fever. The method is still in its childhood, and may be improved. Millions submit to vaccination, typhoid fever is to the layman less terrible than smallpox and it is not so indiscriminate in its attentions, but it is within the bounds of possibility that in time we shall be inoculating against typhoid fever just as we now vaccinate against smallpox.

THE FUTURE OF MEDICAL EDUCATION IN THE UNITED STATES

Medical education in the United States is, at present, in a rather unsatisfactory condition, a condition due mainly to the circumstances under which it has developed. In this country the growth of medical education has followed lines quite different from those along which it has developed in Europe. In Germany and France the medical school has developed as a department of the university, in England under similar circumstances or in connection with a hospital, while in the United States it has usually come into existence as a fruit of the effort of a group of ambitious medical men and has been devoid originally, at any rate, of close official connection with either a university or a hospital. These remarks apply to a majority, but not to all, of the medical schools in this country.

Twenty or twenty-five years ago the student at an American medical school received almost purely didactic instruction supplemented, however, by clinical observation under a preceptor which was often of a most practical kind. The actual instruction in a medical school extended over two short terms, the student hearing the same lectures each year. Later the longer graded course was instituted and the amphitheater clinic came into vogue, and still later laboratory methods of teaching were developed, with the employment by the better

schools of trained laboratory instructors devoting their whole time to the work. At present most, in fact practically all, of the better schools are, to use Barker's classification, on a semi-university basis. The subjects of the first two years are well, in a few instances admirably, taught by men specially trained for this purpose. The work of the last two years is still in the hands of the men who have by dint of hard work and natural ability risen above the rank and file, and stand in the forefront of the profession. Many of these men are good teachers, some are great teachers, but they are the busiest practitioners of the cities, and their practice, their livelihood, has, of necessity, first call on their time and their energy. The teachers in the clinical branches in some schools receive no remuneration, in others a scanty pittance, in a few a salary on which they can exist with the aid of consultation work. Not once but scores of times have these clinical teachers made the greatest sacrifices in the cause of teaching. Is it to be expected that the teaching work of these men, no matter how able they are, will compare with the work of men who devote their whole time and energy to the subject?

The changes in teaching have been accompanied as we mentioned recently,¹ by a great increase in the expense of medical education. A well equipped medical college is perhaps the most expensive form of technical school, and if medical teaching is to be put on a proper basis it will become more, rather than less expensive. How to meet the demands of this increased expense is the question which the American medical college must answer. Not only must adequate laboratory facilities be provided, but a teaching hospital under the control of the school is an essential. Not only must the teachers of the scientific branches be adequately rewarded, but the clinical teachers must also receive salaries large enough to enable them at least to make their teaching their primary work. A few schools have met the problem by securing endowments from private sources, more are attempting to meet it by affiliation with rich universities. Up to the present time, however, none of the universities has placed its medical department on a true university basis. Just as the doctor's bill is generally the last to be paid, so the medical department is usually the last to which a university president pays attention.

After all it is the people who are most vitally interested in the question, for it is they who profit by the more thorough training of the physician. Has the general public done its duty by medical education? In some states the state university has a well equipped medical department including a university hospital but there are very few of these. Minnesota has taken the lead not only in providing for high entrance requirements to its university medical school but also in demanding that physicians coming to that state shall be

educated equally as well as those from its own schools. The United States is no longer so thinly populated that there is difficulty in getting a sufficient number of physicians for the scattered population of the country districts. It is no longer so poor that it can not afford well educated physicians. The action already taken by some states indicates the lines along which help must come. The present system, however, presents certain problems. Is each state to aid only its own university medical school? If so, what is to become of the proprietary medical schools? These schools represent hundreds of thousands of dollars of capital, and, more than this, they have been built up by years of often unselfish work. Under present conditions they can not turn out well educated physicians, when the cost of educating a student—if educated as the times and conditions demand—is from two to three times the amount received from him in fees. We are forced to the conclusion, therefore, that the successful medical school of the future must receive aid. Whether such endowment shall come from the state or from private sources local conditions will determine but that such support must come is self-evident.

TYPICAL NOSTRUMS

During the last two years there have appeared in the Department on Pharmacology exposés of some of the most typical nostrums which have exploited the medical profession. No doubt some of our readers have considered it beneath the dignity of *THE JOURNAL* to discuss such preparations and have felt that the space would be better used if filled with scientific articles on subjects of interest to the better class of physicians. On this point there may be room for argument. These exposés are primarily educational in character, they are object lessons to show physicians how they are being imposed on. The preparations exposed have been selected from a mass of similar stuff, not because they are the worst, or the only ones, but because each is the type of a certain feature or aspect of the nostrum business. The large number of these products now offered through physicians to the public—we believe this is a good way of expressing it—as well as the amount of money spent in advertising, show to what extent this business has developed. We wish that every physician could read these articles, and that he would read between the lines as well as on them, so that he might realize the absurdity and disgracefulness of the whole business. In the preceding issue and in this one we have given considerable space—running the exposé as a continued story, as it were—to two proprietary medicines that are such typical nostrums—*outdoing* the average "patent medicine" in many respects—that we are almost persuaded to apologize for noticing them, since one would suppose no intelligent physician would be foolish enough to prescribe them. And yet, according to reports, both the Anasarcin and Anademine companies are prospering, showing that their stuff is largely used. Further these nostrums are representative of a very large class and have many of the

characteristics of the ordinary "ethical" proprietary article. While pretending to give a formula, in both instances the formulas are fakes in that they are incomplete and misleading. Both are typical of the fact that most of the proprietary medicines are simple mixtures, of some value possibly in certain indicated conditions if they are used with caution, while the promoters are lavish in their statements that the combinations are the result of great scientific research, etc. They illustrate further the fact that the majority of such articles are put out by men who know nothing of medicine, pharmacy or chemistry, and yet assume to supply not only the medicines, but all information regarding their use. In this instance there seem to be some doctors mixed up in the business, but so far as we have been able to learn they are not noted for their educational acquirements or superlative knowledge regarding either medicine, pharmacy, chemistry or any other branch of science. We repeat, we publish this and similar matter for the enlightenment of the profession in regard to some phases of this nostrum evil. We make no apology for doing so, but urge every physician to read this matter and, whether or not he is in the habit of prescribing nostrums, to aid the propaganda to suppress them.

PLACES MAINTAINED BY ABORTIONISTS ARE NUISANCES

One of the hardest problems to solve in the attempt to put professional abortionists out of business is the difficulty of obtaining direct evidence of a specific offense. Such evidence, of course, is essential if conviction is sought on the ground that the crime of abortion has been committed. If conviction can be secured on a more general charge, however, the problem seems in a fair way of being solved. In our Medicolegal Department this week¹ a decision of the Supreme Court of New York is reported which has a special significance in this regard, it being the first of its kind in American legal records. The defendant, an advertising abortionist, was charged with maintaining a public nuisance, which under the New York Penal Code is defined as (1) Unlawfully doing an act or omitting to perform a duty, which act or omission annoys, injures or endangers the comfort of persons, or (2) offends public decency. The case was carried to the higher court after conviction of the defendant on the ground that the penal code made abortion a crime of a higher character and that there was no jurisdiction in the trial court of the offense charged as a public nuisance. No previous decision could be found declaring the maintenance of a place kept for such purposes a public nuisance. The court took the broad view that it was not necessary, as was technically claimed, that the actual commitment of the crime should be proved to bring the case under the statute. The offense of inviting the performance of abortion and maintaining premises for its commission is in itself a crime against order and public decency. A comprehensive definition such as was adopted by the court should cover a much larger class of offenses, it would seem, than those directly aimed at in

the decision and it ought to be easy hereafter to put down illegal and immoral advertising offenders in New York. A valuable precedent is made also for legal proceedings against like offenses in other states where the technical interpretation of the letter and disregard of the spirit of the law have too often successfully aided open violators of good morals.

COMMITMENT OF SUSPECTED INSANE

Following hard on the Thaw trial, and probably is one of its results, a bill has been introduced in the New York Legislature amending the criminal code of the state in relation to inquiry before trial as to the sanity of a prisoner charged with felony. It makes provision for the commitment to a state hospital for the insane of such a person, at the request of either his attorneys or the prosecuting attorneys, for a period of not less than three nor more than six weeks, within which period it is assumed a correct knowledge of his mental condition can be acquired. The idea is a good one, but the wisdom of the exact time limitations may perhaps be questioned. In a doubtful case, such as are most of those in which the plea of insanity has been raised as a defense, it is not always possible to say that six weeks would be sufficient time to form a positive opinion as to the sanity or insanity of the accused. Most experienced alienists, we think, can tell of cases in which they were not satisfied as to the mental condition of a patient after considerably longer observation than the six weeks here provided for. It is possible for a paranoiac to conceal delusions over long periods and while it would be difficult for the ordinary criminal to simulate insanity successfully it would be rash to say that there might not be some so well posted in the symptoms and capable of self-control as to enable them to leave a doubt as to their mental soundness in the mind of even a skilled observer. Simulation of insanity is not at all confined to the sane, and while it may be very evident, there may be underneath it a real mental aberration that may be aggravated by the attempt to exaggerate. Some authorities have maintained that the attempt to sham mental disease has a direct tendency to produce it. It is very improbable that the patients occasionally discharged from asylums as "not insane" have been detained, as a rule, for so short a period as six weeks, and yet no superintendent would be justified in keeping them a day after he is convinced of their mental integrity. The plan, however, is a good one, and if generally adopted and properly carried out, would be in the interest of justice, would prevent the escape of some criminals from their just desert, and, probably, prevent an occasional judicial murder. It is practically followed out in some parts of the country without special legal provision for it by a little stretching, it may be of existing laws. A properly drawn-up measure analogous to that proposed in New York specifically legalizing the commitment for observation and making due provisions for properly guarding the individuals thus committed (which can not ill be done in an ordinary way) would be still better.

Medical News

ALABAMA.

Society Meetings—At the annual meeting of the Marengo County Medical Society, held in Linden, April 13, the following officers were elected: President, Dr. Andrew P. McArthur, Rembert, vice president, Dr. John C. Christopher, Nanafalia, censor, Dr. James D. Jones, Sweetwater, treasurer, Dr. James B. Whitfield, Demopolis, secretary, Dr. Offa L. Shivers, Jr., Linden, and health officer, Dr. William L. Kimbrough, Linden.

—At an enthusiastic meeting of the alumni of the Medical Department of the University of Alabama, held at Mobile Medical College, April 16, the alumni association reorganized and elected the following officers: President, Dr. Louis W. Johnston, Tuskegee, vice presidents, Drs. Lewis W. Desprez, Florence, and Charles Whelan, Birmingham, and secretary, treasurer, Dr. Percy J. Howard, Mobile.

—At the twelfth annual session of the Alabama Medical, Dental and Pharmaceutical Association (colored), held at Birmingham, April 11 and 12, Montgomery was chosen as the next place of meeting and the following officers were elected: President, Dr. George H. Wilkerson, Mobile, vice president, Dr. Cato H. Wilson, Eufaula, William Hawkins, Montgomery, Dr. L. Johnson, Birmingham, and U. C. Robinson, Ensley, secretary, Dr. Lincoln L. Burwell, Selma, assistant secretary, Dr. W. H. Brummit, Taladega, treasurer, I. B. Kigh, Birmingham, and delegate to the National Medical Association, Dr. Willis W. Steers, Decatur.

CALIFORNIA

Trachoma at Fresno—Thirty cases of trachoma are reported among Russian and Japanese immigrants at Fresno.

Public Health Association Meets—The second annual meeting of the California Public Health Association was held at Del Monte, April 15. The association recommended that a law be passed appointing a medical officer to every school to investigate the health conditions prevailing, and also make a thorough investigation of the eyes and ears of all scholars and to advise with the parents concerning the advisability of compelling weak children to attend school. Dr. Antrim E. Osborne, Santa Clara, was elected president, and Dr. Charles F. Clark, Woodland, vice president. The next meeting of the association will be held at Woodland in October.

State Society Election—At the annual meeting of the Medical Society of the State of California held at Del Monte, Monterey, April 16 to 18 the following officers were elected: President, Dr. George H. Evans, San Francisco, vice presidents, Drs. James A. McKee, Sacramento, and John C. King, Banning, secretary, Dr. Philip Mills Jones, San Francisco, delegates to the American Medical Association, Drs. H. Bert Ellis, Los Angeles, Philip Mills Jones, San Francisco and Oliver D. Hamlin, Oakland, alternates, Drs. Henry M. Pond, Alameda, Charles C. Browning, Monrovia, and William F. Snow, Stanford University and councilors, Dr. George H. Kress, Los Angeles, succeeding Dr. H. Bert Ellis, Dr. Fred R. Burnham, San Diego, succeeding Dr. Ashley S. Parker, Riverside, and Dr. Henry A. I. Rykfogel, San Francisco, succeeding Dr. George H. Evans. The House of Delegates approved the efforts made toward securing the new law and, in fact, approved all acts of councilors and officers during the year. The House of Delegates also instructed the publication committee to advertise no preparations not approved by the Council on Pharmacy and Chemistry, but to continue until their expiration all existing contracts. Coronado was selected as the meeting place for 1908.

Personal—Dr. Fred L. Zumwalt has been appointed assistant surgeon of the Emergency Hospital, San Francisco, to succeed Dr. Charles B. Pinkham.—Dr. Edward C. Sewall has been appointed eye specialist at the San Francisco County Hospital.—Dr. James W. Ward, San Francisco, has resigned from the health commission. Dr. Jules A. Simon has been elected president of the board and Dr. Henry D'Arcy Power a member.—Dr. W. R. Ingersoll, Fresno, has been appointed physician at the state prison, Folsom, vice Dr. Charles F. Gladding, Represa, resigned.—Drs. Sumner J. Quint and Edward H. Carrett have been appointed surgeons at the City Hospital, Los Angeles.—Dr. Ethel L. Leonard, city bacteriologist of Los Angeles, has resigned.—Dr. Warren N. Horton, formerly of St. Louis, has been appointed city bacteriologist of Los Angeles.—Dr. Stewart McL. Doherty has been appointed third assistant physician at the State Hospital, Napa, to succeed Dr. Isadore F. Cohn.—Dr. Thomas M. Hayden has been re-elected city health officer of Fresno and secretary of the local board of health.—Dr. F. W. Alexander, San Fran-

cisco, commander of Camp 30, was presented with a silver loving cup by the residents of the camp, April 15, on the eve of his departure for Europe.

ILLINOIS

Banquet at New Hospital—The banquet for the medical staff of the Oak Park Hospital, which was postponed from March 4, on account of the illness of Dr. John W. Tope, chief of staff, was held May 4. Bishop E. J. Dunne, Dallas, Texas, gave the opening address. Dr. William A. Evans, health commissioner of Chicago, was toastmaster. Addresses were made by several physicians of Chicago.

Free Distribution of Antitoxin—Under the omnibus appropriation bill the State Board of Health will be allowed \$15,000 yearly for free distribution of antidiphtheritic serum outside of Chicago. The appropriations of the State Board of Health have been materially increased also, by this bill, the sum of \$119,200 having been appropriated for the work of the board, against the sum of \$83,320 granted by the General Assembly of 1905.

New Medical Practice Act—A bill introduced at the instance of the State Board of Health, and now on final passage in the senate, will confer specific authority on the State Board of Health to establish standards of preliminary education and to determine the standing of literary scientific and medical schools, will provide for reciprocal registration of licenses, will allow the members of the board compensation for their services, and will remedy a defect in the act of 1899 by giving the State Board of Health jurisdiction over all licenses issued since July 1, 1877.

New Sanitary Act—A bill conferring additional powers on the State Board of Health has passed both houses. It gives the board supreme authority in all matters of quarantine and makes it the duty of all local boards of health to enforce the rules and regulations adopted by the state board. A severe penalty is provided for violation of the regulations of the State Board of Health, which is empowered to enforce health measures in cities and villages when the municipal authorities neglect or refuse to act with sufficient promptness or efficiency, and to collect from the city or village all necessary expenses incurred.

Osteopath Bill Killed—House bill No. 318, to place an osteopath on the State Board of Health, failed of passage in the house, May 2. Another bill was designed to establish a standard for medical and osteopathic schools, to license osteopaths without examination, and to confer on them "all the rights and privileges which physicians in the state now have." The State Board of Health was characterized as "an arrogant and arbitrary body having absolute power over the standards of medical schools." The bill met with the fate of the several osteopathic bills introduced in the Illinois General Assembly since 1897.

Reciprocity and the State Board of Health—At a meeting of the Illinois State Board of Health and the officers of the Illinois State Medical Society, the Illinois Homeopathic Medical Association, the Illinois State Eclectic Society and the Illinois Physio Medical Society, held in Chicago, April 24, the committee on reciprocity appointed at the meeting held April 6, made the following report:

- 1 After investigation the committee wish to express its hearty approval of the work of the Illinois board in promoting better reciprocal relations between states.
- 2 We believe the plan of the Illinois board in giving credit to the old practitioner for years of practice is an eminently just and fair one, minimizing as it does the inconvenience to older practitioners.
- 3 We believe that under the present law the board can take no other position regarding the licensing of practitioners from other states.
- 4 We believe that still better reciprocal relations between Illinois and other states would be possible if the present law could be amended so as to allow the board at its discretion to grant licenses without examination to practitioners from other states who were in practice before the adoption of the present medical practice act in Illinois.

The conference approved the first three sections of the report. After a lengthy discussion, which was participated in by every physician present, the conference by unanimous vote, rejected the proposed amendment to the law. The committee stated that the recommendation for the plan of reciprocity suggested in Section 4 was made for the express purpose of learning the views of the representatives present at the meeting as the State Board of Health had been criticised for not reciprocating in the case of licenses issued on diplomas and without examination.

Chicago

Personal—Dr. Emanuel I. Senn returned from Europe, May 5.—Dr. L. Blake Baldwin was appointed city physician, May 6.

Ex-Internes Banquet—The Society of Ex-Internes of St Luke's Hospital held its annual meeting and banquet April 27. Dr James T Campbell was elected president, and Dr George J Baxter, secretary.

Killian to Give Clinic—Professor Killian of Freiburg Germany, will give a clinic at Rush Medical College on diseases of the nose and throat May 15, at 2 p m, to which the profession of the city is invited.

Mortality to May 1—During the first four months of 1907 12,075 deaths were reported, an increase of 2,059, or of 17.3 per cent over the same period of 1906. The increase in mortality was chiefly in diseases of the respiratory tract, chronic affections and acute communicable diseases.

Mortality for the Week—During the week ended May 4 there were 764 deaths reported equivalent to an annual rate per 1,000 of 18.90. Pneumonia caused 170 deaths or 52 more than the preceding week, consumption 81, nephritis 59, heart diseases 58, violence (including suicide), 44, scarlet fever, 16, diphtheria, 11, measles, 9, whooping cough, 8, and influenza, 4.

April Deaths—During April there were reported 2,971 deaths, 271 more than for the corresponding period of 1906 and nearly 1,000 less than for March, 1907. As compared with March there were 112 fewer deaths from pneumonia, 47 fewer from consumption, 20 fewer from scarlet fever. Acute intestinal diseases caused 46 more deaths, nervous diseases, 39, nephritis 22, diphtheria 22, and measles, 18.

National Guard Changes—Major Charles Adams has resigned as surgeon of the First Infantry and has been made secretary to the surgeon general—Captain Samuel C Stanton has passed his promotional examination, and Dr Daniel W Rogers his examination for the medical department, and they will be assigned as major and surgeon and first lieutenant and assistant surgeon, respectively, to the First Infantry—Dr Harry D Orr has passed his examination and will be commissioned first lieutenant and assistant surgeon, and assigned to the First Cavalry.

INDIANA.

Schools Not Closed—Dr Edmund S Imel, secretary of the Petersburg board of health, states that the schools have not been closed and that there has been no scarlet fever in the town within twelve months.

Communicable Diseases—More than a thousand cases of measles of a mild type are reported in Muncie and Delaware County—Dr Edgar C Loehr, health officer of Hamilton County, reports eight cases of smallpox at Atlanta.

Personal—Dr Arthur B Crav has been appointed health officer of Monticello, vice Dr Grant Goodwin, resigned—Dr Thomas P Seller, one of the oldest practitioners of Indianapolis, is critically ill—Dr Marquis Greenwalt, Fort Wayne, who is seriously ill, has been removed from his residence to Hope Hospital.

Graduation—The graduation exercises of Indiana Medical College College of Medicine of Purdue University, Indianapolis, were held May 1 at Lafayette. A class of 70 was presented to the dean, Dr Henry Jameson. The degrees were conferred by President W E Stone of the university, and the address of the day was by President George L McIntosh of Wabash College on "Artists and Hacksters." The faculty of the college entertained the graduating class at a banquet in Indianapolis April 27, at which Dr John H Oliver acted as toastmaster.

IOWA

State Society Meeting—The fifty-sixth annual meeting of the Iowa State Medical Society will be held at Cedar Rapids May 15 to 17. The headquarters are the Montrose Hotel, and the sessions will be held in the Auditorium.

Cerebrospinal Meningitis—Meningitis is reported prevalent in the northwest part of Appanoose County—There are reported to be more than 20 cases in the village of Mystic and the surrounding mining camps—Three cases are reported at Ankeny with one death.

Personal—Dr John N Warren, Sioux City, sailed on the *Deutschland* from New York April 30—Dr Herbert M Decker has been appointed to take charge of the bacteriologic laboratory establishment in Davenport by the State Board of Health—Dr Emil O Ficke, Davenport, has been appointed physician of Scott County, vice Dr Charles L Barewald—Dr A Sidney Bowen, Waukon, has been appointed to a position in the medical service of the Canal Zone—Dr W Pitt Norris, Birmingham, was stricken with a cerebral hemorrhage April 20—Dr and Mrs R O Shelton, Bloomfield, left for their future home in San Diego Cal., April 27.

Alumni Meeting—The third annual meeting of the medical alumni association of the College of Medicine of the State University of Iowa, Iowa City, was held April 30 and May 1. On the first day an address of welcome was delivered by Dr James R Guthrie, Dubuque, dean of the College of Medicine. In the afternoon clinics were held and in the evening Dr Mazvek P Ravenel, Philadelphia, delivered an address illustrated by lantern slides, demonstrating on "A Modern View of Tuberculosis and the Role of Sanatoria." A printing of Dr Clinton J Schrader was presented to the university by Dr James R Guthrie and was received for the university by President George E McLean. On the second day Dr Joseph C Bloodgood, Baltimore, held a surgical clinic. Dr Ravenel delivered an address on the histology of tuberculosis and other demonstrations were held. In the evening the annual banquet was given at the Burkley Imperial.

KENTUCKY

Personal—Dr Martin J Bartlett, Louisville, is at present in Riverside Cal—Dr Flavius J Taylor, Glasgow, is reported to be critically ill at his home.

Hospital to be Established—At the last meeting of the Mercer County Medical Society a movement was inaugurated to establish a hospital at Harrodsburg. A committee was appointed to consider plans and details.

LOUISIANA

Gift to Infirmary—Mr Isidore Newman presented \$5,000 to the Touro Infirmary on his seventieth birthday.

Insane Hospital to be Rebuilt—The estimate of the local contractor as to the damage by the cyclone at the State Insane Hospital, Jackson, is \$47,000 and immediate action is to be taken toward restoration of the building.

Medical Society Meeting—The East Baton Rouge Parish Medical Society, at its annual meeting held in Baton Rouge, May 14, elected Dr Charles D Simmons, president, Dr John A Caruthers, vice president, and Dr Joseph E Heidingerfeld, secretary and treasurer.

Tuberculosis Sanatorium—A sanatorium for the treatment of tuberculosis is soon to be established in St Tammany Parish. Mr N O Nelson of St Louis has donated \$1,000 for the initial expenses. The institution is to be operated under the auspices of the New Orleans Anti-Tuberculosis League.

Personal—Dr Clarence E Hutchinson has been appointed superintendent of Touro Hospital, New Orleans, vice John E Ellis, and Dr Ansell M Kane has been appointed junior interne to fill vacancy—Drs Dominique J Cragnon and Arthur Gilbeau have been appointed members of the board of health of Breun Bridge.

MAINE

Change of Date—The annual meeting of the Maine Medical Association will be held in Lewiston June 12-14, instead of June 5-7.

Hospital for Bath—The business men of Bath plan a city hospital, for which the late Miss Lucinda Bailey left \$5,000. A like sum may be needed for equipment.

Son, Not Father, Moved—The notice in THE JOURNAL April 27 that Dr Walter L Hunt had removed from Bangor to Island Falls was incorrect. Dr H I Hunt, a son of Dr W L Hunt, has removed to Island Falls, succeeding to the practice of Dr Frederick W Mitchell.

Home for Feeble-Minded—At the annual meeting of the Rockland Board of Trade resolutions were adopted pledging the board to attempt to secure a location of the Home for the Feeble Minded at Rockland. It is proposed to secure about 500 acres of land in the western section of the city for this purpose.

MARYLAND

New Secretary for State Board—Dr Marshall J Price has been elected secretary of the State Board of Health, vice Dr John S Fulton, resigned.

Health Report—Of the 186 deaths in Baltimore during the week ended May 4, 30 were from pneumonia. During the week 113 cases of measles were reported to the health department.

Honor for Carroll—The University of Maryland will confer the honorary degree of LL.D. on one of its alumni, Major James S Carroll, United States Army, at the centennial celebration to be held in Baltimore May 30 to June 2.

Society Meeting—At the annual meeting of the Cecil County Medical Society at Fikton, Dr Robert M Black, Cecilton, was elected. Dr George S Dure, Rising

Sun, vice president, Dr Howard Bratton, Elkton, secretary and treasurer, and Dr Theodore A Worrall, Northeast, censor

MASSACHUSETTS

To Lay Dust—In response to a request from the Brookline Medical Club to allay the nuisance of dust on the streets, the selectmen of that town—"the richest in America"—have experimented with the chlorid of calcium process and have decided to apply it to the 65 miles of macadam roads in the town.

Disease and Death—There were reported to the Boston board of health for the ten weeks ended May 4, 2,362 deaths, as against 2,384 in the corresponding period in 1906, equivalent to an annual death rate of 20.45 per 1,000. During this time there were 500 cases of diphtheria, with 32 deaths, 480 of scarlet fever, with 9 deaths, 53 of typhoid fever, with 4 deaths, 126 of measles, 524 of tuberculosis, with 257 deaths, and 2 of smallpox. Pneumonia caused 335 deaths, whooping cough, 7, heart disease, 258, bronchitis, 62, marasmus, 26. Of those who died 383 were under one year old, 523 were under 5 years old, and 591 were over 60 years of age.

MICHIGAN

Typhoid Fever—Escanaba is said to be suffering from a heavy epidemic of typhoid fever. There were reported to be at least 150 cases in the city.

Medical Journals Combine—The *Detroit Medical Journal* has absorbed *Leonard's Illustrated Medical Journal*, Detroit, taking over both the advertising contracts and the circulation list, beginning with the April issue.

Raises Entrance Standard—The board of regents of the University of Michigan, at its meeting April 19, decreed that "Beginning with the class to enter in the fall of 1909, every candidate for the degree of M.D. in the College of Medicine and Surgery of the University of Michigan shall show a certificate that he has had two years' work in the literary department of some first class college."

Personal—Dr Berten M Davey has been elected city physician of Lansing.—Dr Walter H Sawyer, Hillsdale, is seriously ill with septicemia.—Dr Ethan A De Camp, Bannister, has been appointed health officer for Elba Township, vice Dr Charles F Patton.—Dr Anson A Smith, Muskegon, has recovered from his recent illness.—Dr Edward P Waid Salem, has been appointed township health officer.—Dr Frances A Rutherford, Grand Rapids, returned May 1, after a few months spent in Southern California.

MISSOURI

Personal—Dr Jesse L. Laton, Bismarck, has been appointed a member of the board of management of the State Sanatorium for Tuberculosis, Mount Vernon.—Dr Robert M Cowan, Springfield, has been appointed health commissioner.—Drs Julius Frischer, Paul Lux, Thomas C Unthank, William A Shelton, William L Gist and Ford B Rogers have been appointed city physicians, and Dr Eugene Carbaugh has been appointed quarantine physician of Kansas City.

Cancer Hospital Report—Since the establishment of the St. Louis Skin and Cancer Hospital in July, 1905, 522 cases have come under the supervision of the institution, 439 of which were hospital cases. In the hospital 151 tissue and 288 organic examinations were made. During the first 18 months \$15,323.92 was expended of the \$15,005.94 on hand, leaving a cash balance of \$283.02. The total amount of subscriptions promised is \$40,495.10 and the cash on hand at the end of the fiscal year \$8,196.02. The report shows that \$12,500 additional is needed to carry out the work for the remaining term of three and one half years.

NEBRASKA

Society Meeting—At the annual meeting of the Republican Valley Medical Society, held in Holdrege, Dr Elbert E Cone, Oxford, was elected president, Dr William A. Schreck, Bertrand, vice president, Dr Joseph N Campbell, Stamford, secretary, and Dr Peter A Sundbury, Holdrege, treasurer.—Cass County Medical Society at its annual meeting, held in Iowaville, elected Dr James B Hungate, Weeping Water, president, Dr Theodore P Livingston, Plattsmouth, vice president, Dr J E. Wortham, secretary-treasurer, and Dr Hungate, delegate to the state society.—At the annual meeting of the Hall County Medical Society, held in Grand Island, Dr Weiss was elected president, Dr J Lue Sutherland, Grand Island, vice president, and Dr Benjamin R McGrath, Grand Island, secretary-treasurer. The society passed resolutions prohibiting the use of members' names in local news

papers in connection with medical or surgical cases.—The Box Butte County Medical Society held its annual meeting at Alliance and elected the following officers: President, Dr Harvey H Bellwood, vice president, Dr G W Mitchell, secretary-treasurer, Dr John E Moore, and censors, Drs Luther W Bowman, G W Mitchell and E E Barr, all of Alliance.

NEW YORK

Smallpox Closes Schools—The schools of Dundee have been closed indefinitely on account of smallpox.

Signed by the Governor—Senator Page's bill, amending the charter of the Medical Society of the State of New York relative to defense of actions, has been signed by the governor.

Commencement—At the commencement exercises of Albany Medical College, May 3, a class of 40 was graduated. The diplomas were conferred by Chancellor Raymond and the address to the graduates was delivered by Joseph A Law-on of Albany.

Personal—Dr Albert Vander Veer of Albany was the guest of honor at a dinner at the Hotel Ten Eyck, given by more than 100 of the students, who have from time to time been his students. A silver loving cup was presented to Dr Vander Veer.—Dr John M Farrington, Binghamton, read a paper before the Broome County Medical Society, April 3, entitled "Fifty Years in the Practice of Medicine," in which he gave reminiscences of his half century of practice in which he named in chronological order the members of the profession in the city who had died in the last 21 years.—Dr William W Carleton has been reappointed health officer of Waterloo.—Dr Charles W Pilgrim has resigned as superintendent of the Hudson River State Hospital, Poughkeepsie.—Dr Warren L Ayer, Owego, is ill with pneumonia.—Dr Robert Knight, Seneca Falls, has been appointed city physician.—Dr Frank W Sears, Binghamton, has been commissioned assistant surgeon, N Y N G, with the rank of captain, and assigned to duty with the First Infantry.

New York City

Trachoma in Public Schools—The oculists of the health department have just completed a special investigation of trachoma among the children in the schools, and the report shows that there are 8,700 cases instead of 10,000 as had been estimated. It was also stated that operative treatment gave better results than non operative, as 70 per cent of the cases treated by surgery were cured.

Personal—Dr Joseph D Bryant had the degree of doctor of laws conferred on him at the quarterly meeting of the faculty of Cornell University Medical College, April 27. Dr Bryant has been connected with the college as professor of anatomy and professor of surgery for 39 years.—Dr Charles H Archibald, while in his automobile, collided with a car and was thrown out and cut and bruised about the head.

Contagious Diseases—For the week ended April 27 there were reported 543 cases of scarlet fever, with 26 deaths, 477 cases of measles, with 17 deaths, 407 cases of tuberculosis with 227 deaths, 339 cases of diphtheria, with 30 deaths, 100 cases of typhoid fever, with 18 deaths, 60 cases of whooping cough with 11 deaths, 20 cases of cerebrospinal meningitis, with 17 deaths, 1 case of smallpox, and 96 cases of varicella, making in all 2,034 cases, with 356 deaths.

Moving Day for Hospitals—On April 29 the Harlem Hospital moved into its new structure on Lenox Avenue, between One Hundred and Thirty-sixth and One Hundred and Thirty-seventh streets. There is room in the new building for 200 patients. Following this move there will be a change in the district covered by the Harlem ambulances of which there are five. On the same day the Fordham Hospital moved into new quarters. The new hospital accommodates 150 patients and is located at Southern Boulevard and Crotona Avenue.

A Paying Philanthropy—As a result of the movement to improve the dwellings of the poor which was started a few years ago four large groups of houses have been erected at a cost of about 2,000 families. The secretary of the association reports that in 1906 there were in these tenements 104 births and 17 deaths. In one group of houses where there were 400 children there were only three deaths during the year. In another group there were no deaths. In addition to the improved condition of the people, these modern tenements have yielded a return of 4 per cent on the money invested, although the enterprise was not intended as a money-making venture.

Appropriation for Milk Booths—By a unanimous vote the board of aldermen requested the board of estimate to authorize the issue of \$8,000 of special revenue bonds for the erection

of stands in the parks for the sale of milk. A personal appeal was sent to each alderman by the Woman's Municipal League asking for the passage of the resolution. The New York City Federation of Woman's Clubs also adopted a resolution calling on the city to provide temporary structures for the distribution of pure milk for the children of the tenements. Nathan Strauss has offered to provide an abundant supply of pasteurized, modified milk, in nursing bottles, and by the glass, in addition to providing competent medical supervision of the work, if these structures are built.

NORTH CAROLINA

Commencement—The commencement of the Medical Department of the University of North Carolina, Chapel Hill, was held May 8, when diplomas were awarded to a class of 11.

New Building for North Carolina College—The University of North Carolina will erect a larger building for the medical department. A committee of the trustees was appointed to arrange for its erection.

State Sanatorium—Dr James E. Brooks, Greensboro, has been elected superintendent of the State Sanatorium for Tuberculosis, Jackson Springs. The executive committee has been authorized to erect suitable buildings and to open the sanatorium, as provided for by the state legislature. It is reported that a location has been selected in Moore County.

District Association Meeting—At a regular meeting of the Tenth Councilor District Medical Society, held at Asheville, April 16, the following officers were elected: President, Dr. Lewis B. McBrayer, Asheville, vice presidents, Drs. William Redin Kirk, Hendersonville, Sheridan C. Highway, Murphy, and Charles E. Reed, Asheville, and secretary, Dr. Gaillard S. Tennent, Asheville.

OHIO

Hospital Changes Ownership—The Seton Hospital, Cincinnati, conducted by the Sisters of Charity, has secured possession of the Presbyterian Hospital property for \$50,000. The present hospital will probably be used as a home for the sisters.

Typhoid Fever in Cincinnati—Nearly 2,200 cases of typhoid fever have been reported in Cincinnati since June 1, 1906. This includes the 24 wards of the city and public institutions, but not the outlying villages. This would seem to be a good argument for the completion of the new waterworks.

Personal—Dr. O. H. Pinney, Cincinnati, has been appointed by the Presbyterian Board of Foreign Missions a medical missionary to Benito, West Coast of Africa, and leaves for his post of duty in July. Dr. Lester Keller, Ironton, has been appointed local surgeon for the Detroit, Toledo and Ironton Railway. Dr. Paul Gillespie has been elected health officer of Wyoming, Cincinnati. Dr. Anthony G. Kreidler has been made editor, and Dr. George Strobach, managing editor, of the Cincinnati *Lancet Clinic*.

PENNSYLVANIA.

Typhoid Epidemic—There is an epidemic of typhoid fever in the vicinity of Bechtelsville, near Reading. Thus far there have been three deaths.

Vivisection Bill Dropped—Representative Townsend's bill to prohibit vivisection has been dropped from the calendar in the legislature. This action followed an address in opposition to the measure made to fifty members of the house by Dr. S. Weir Mitchell of Philadelphia.

Hospital Overcrowded—The State Miners' Hospital, Hazelton, is so overcrowded that it has been necessary to install additional beds for the accommodation of patients, of whom 53 are being treated. During the past few months more than the usual number of accidents have occurred in and about the mines, and the daily average of patients has been from 48 to 50.

Philadelphia

The Meningitis Situation—Six new cases of cerebrospinal meningitis were reported in the city during the past few days, but the authorities assert that there is no occasion to fear an epidemic.

Will Erect Food Laboratory—The Philadelphia College of Pharmacy will erect and equip a laboratory for the analysis of foods and drugs by October next, to meet the growing demands for analyses created by the national Food and Drugs Act.

Tuberculous Dispensary Opened—A free dispensary for the treatment of patients suffering with tuberculosis was opened at the Jewish Hospital May 6. This is the first hospital in

the city to establish a separate dispensary of this character. Dr. Wilfred Fetterman of the Henry Phipps Institute has been placed in charge of the work.

Resident Physicians Organize—Dr. Anthony Harrigan, ex-resident physician at St. Joseph's Hospital, was tendered a reception at the Hotel Majestic by the staff of the hospital, and the Association of Residents and ex-Residents of that institution. Dr. Edward E. Montgomery was chairman of the meeting. At this time a permanent organization of the residents and ex-residents of the hospital was effected.

Personal—Director Neff has made the following appointment to fill honorary position at the Philadelphia Hospital: Neurologist and consultant, insane department, Dr. Theo. H. Weisenburg, to succeed Dr. William C. Pickett, deceased. Dr. Weisenburg was recently appointed professor of neuro pathology and assistant professor of neurology at the Medico-Chirurgical College. Vice Dr. Pickett—Dr. W. M. Late Coplin, professor of pathology in Jefferson Medical College, has been appointed medical director of the Jefferson Medical College Hospital, vice Dr. Joseph Neff. Dr. Neff still retains his position as president of the medical staff, and is the newly appointed director of the city's department of health and charities.

Semi-Centennial of Pathological Society—The semi-centennial of the founding of the Pathological Society of Philadelphia was celebrated May 9 and 10 by a series of entertainments and scientific discussions, and an exhibition of pathologic specimens. These covered a wide field of pathology and were of very great interest. The exhibition was held in the Mütter Museum of the College of Physicians May 9. On May 10 the program consisted of the presentation of the following papers: "The Role of Protozoa in Pathology," by Dr. Frederick G. Novy of the University of Michigan, "The Dynamic Point of View in Pathology," by Prof. Alonzo E. Taylor, University of California, "The Newer Pathology," by Dr. Simon Flexner, Rockefeller Institute, and "Pathology and Practice," by Dr. William Osler, Oxford University, England. A luncheon was given to the members at the University Club May 10, and on the same evening a banquet was tendered the visiting guests at the Bellevue Stratford Hotel.

WASHINGTON

Personal—Dr. Philip Frank, North Yakima, has been appointed county physician of Yakima County, vice Dr. Thomas Tetreau, term expired. Dr. Montgomery Russell, Seattle, is taking a trip to the Atlantic seaboard.

Loses License—In the case of the State Board of Medical Examiners against James G. Stewart, Seattle, the Supreme Court is reported to have decided in favor of the plaintiff, confirming the original sentence of revocation of license.

The Fight Against Tuberculosis—The Yakima County Medical Society has undertaken to give a number of lectures in the public schools on the proper treatment of tuberculosis. The lectures will be supplemented with pamphlets on the prevention and treatment of tuberculosis prepared by the Washington Association for the Prevention and Relief of Tuberculosis. At a recent meeting of the Snohomish County Medical Association it was decided to organize an auxiliary to the Washington Association for the Prevention of Tuberculosis and a committee was appointed to make the necessary arrangements.

Meningitis—A death from cerebrospinal meningitis was reported April 14 at Gray's Harbor. During March there were 31 deaths in Seattle from cerebrospinal meningitis, and during the first thirteen days of April 8 deaths occurred. The Snohomish County Medical Association, at a meeting April 2, decided to advise the health officer to placard for cerebrospinal meningitis. Dr. Wilbur N. Hunt, health officer of Bellingham, reports 10 cases of cerebrospinal meningitis with 5 deaths. Dr. Rose A. Bebb, city bacteriologist of Tacoma, reports up to April 4, 42 cases of spinal meningitis. The majority of patients were between 10 and 20 years of age and the epidemic is apparently subsiding.

GENERAL

Personal—Dr. William Osler, regius professor of medicine at the University of Oxford, England, arrived in New York April 27.

No Liquor for Lepers—The legislative committee which recently visited the leper settlement at Molokai has reported adversely on the petition that the sale of liquor be permitted in the settlement.

Board of Food and Drug Inspectors Appointed—The Secretary of Agriculture has created a board of food and drug

inspectors, consisting of Dr Harvey W Wiley, chief of the Bureau of Chemistry, Dr Frederick L Dunlap, associate chemist, and George R McCabe, solicitor of the Department of Agriculture

Plague in Hawaii—Four cases of bubonic plague are reported in Honolulu, with three deaths. All the patients were Japanese and on the same plantation. Samples of imported oriental foods were examined, but no clue to the infection was obtained. Several rats had died on the plantation and their bodies had been burned.

Medical College Association Meeting—At the annual meeting of the Association of American Medical Colleges at Washington, May 6, Dr Henry B Ward, Lincoln, Neb., was elected president, and Dr Fred C Zapffe, Chicago, was re-elected secretary-treasurer. A report of the meeting will appear in THE JOURNAL later.

American Society of Sanitary and Moral Prophylaxis.—At a meeting held in New York City, April 11, the following officers were elected for the ensuing year: President, Dr Prince A Morrow, New York City; vice presidents, Prof Edwin R. A Seligman, Dr Stephen Smith and Mr Francis Lynde Stetson, secretary, Dr Edward L Keyes, Jr., and treasurer, Dr Smith Ely Jelliffe, all of New York City.

Mosquito Fighters Meet.—The fourth annual meeting of the American Mosquito Extermination Society was held at the Union League Club, New York City, April 19. Dr L. O. Howard, Washington, D. C., the government's chief entomologist, was present and told of his work. Dr E. Porter Felt, the state entomologist, emphasized the need of state appropriation in order to study the habits of the pest.

Health of Canal Zone.—The health conditions of the Canal Zone for March are reported to be excellent. Since August last the number of sick among the employes has steadily decreased, until it is now 1940 per 1,000, as against 3372 in August. Among the 4,600 white employes there were only two deaths from disease during the month of March, equivalent to an annual rate of 5.17 per 1,000. Among the 1,200 American women and children living in Canal Commission quarters there were no deaths and little sickness. The mortality from all causes for March was: Negroes, 48.50 per 1,000, white employes, 15.69, and American whites, 10.34 per 1,000.

American Anti-Tuberculosis League.—The American Anti-Tuberculosis League, organized to prevent consumption, to educate the people, to secure state aid and to establish hospitals, etc., will hold its next meeting, June 1 to 4, 1907, at Atlantic City, N. J. Special subjects for discussion will be "Tuberculosis and Milk" and "Tuberculosis in the Negro Race." Hon Nathan Strauss, New York, who has done so much for the bettering of milk supply, will preside at the meeting which takes up the subject of milk. Further information may be obtained from Dr George Brown, Atlanta, Ga., president and executive officer.

Carter Suggested for Opium Commission.—In the event of an international conference being called to inquire into the use of trade in and laws pertaining to opium in eastern countries it is probable that one of the members of the commission will be a representative of the United States, and for this place the *Leavenworth Times* suggests Major F. Champe Carter, Medical Department U. S. Army, as the best man, since he was a member of the opium commission appointed by Secretary Taft when governor of the Philippines, as he is said to know more about the opium question than any other man in the United States and as no representative could be found who is so familiar with the subject and so well able to plan for the elimination of the evils of the opium traffic as he.

The International Congress on Tuberculosis.—The assembling of this congress in Washington during the last ten days of September and the first ten days of October 1908 will call together a large number of distinguished men from all parts of the world. The National Association for the Study and Prevention of Tuberculosis has chosen the time and place for the congress to suit the pleasure and convenience of the foreign members and delegates and the officers believe that the congress will be a success and will demonstrate the interest of the American public in the subject of tuberculosis notwithstanding the fact that the country will be preoccupied at the time with an exciting political campaign. A tuberculosis exhibition which is expected to surpass anything of the sort ever attempted is contemplated. In addition to its interest to the medical profession the congress will appeal to public sanitarians and philanthropists to those interested in social science and to veterinarians. The various departments of the government have become interested and are making preparations

which will ensure the proper representation of the United States. The National Association for the Study and Prevention of Tuberculosis will provide a fund of \$100,000 for the expenses and this sum will come chiefly from the private purses of a few wealthy and enlightened men who see in this congress an opportunity to give a tremendous impetus to the movement against tuberculosis.

CANADA

Army Medical Corps in Winnipeg.—An army medical service corps was organized in Winnipeg, April 16. Dr William Webster will command the new unit, with rank of major, Dr Borden will be second in command, with rank of captain, and Drs D. S. McKay and Boardman will be lieutenants.

Inspection of Schools.—Medical inspection of schools in Montreal for the six months ended March 31 showed that 20,082 pupils were affected. Montreal's medical health officer is urging the council to provide funds for the continuance of this work.

Canadian Wins English Prize.—Dr Don Armour, London, England, University of Toronto, 1904, house surgeon in Toronto General Hospital in 1904 and 1905, has been awarded the Jacksonian prize, for 1906, by the Royal College of Surgeons, England. This is the first time the prize has gone to a Canadian. The title of his essay was "Diagnosis and Treatment of Those Diseases and Morbid Growths of the Vertebral Column, Spinal Cord and Canal, Which Are Amenable to Surgical Operation."

Personal.—Dr Kenneth Pantton, Portland, Ore., is passing through Canada en route to London, Eng., for graduate work in connection with the Fellowship of the Royal College of Surgeons. Dr J. R. Jones, Winnipeg, professor of medicine in the University of Manitoba, who has been recuperating in Toronto from a fractured pelvis received in a runaway accident, is going to England. Dr Robert Law has been confirmed as medical health officer of Ottawa. Dr Andrew B. Eadie, Toronto, is critically ill. Dr Frederick B. Bowman, Kingston, has been appointed assistant in the United States Government Laboratory, Manila, P. I. Dr Edwin S. Popham, Winnipeg, has returned home after a few weeks in Chicago. Dr William P. Caven, Toronto, is at Atlantic City. Dr Harry J. Watson, United States immigration officer at Winnipeg, is recuperating in Toronto after an operation for duodenal ulcer. Dr George R. McDonough, Toronto, has returned from Egypt.

FOREIGN

Venereal Prophylaxis in German Technical Schools.—By a recent ministerial decree the directors of the technical schools are instructed to make provision to have the medical inspectors of the schools give instruction in sexual hygiene at the beginning of the school year.

Postage Stamps to Raise Funds for Public Health Campaign.—A special stamp is now on sale in Germany at a slightly increased price (5 pfennige), the surplus to be devoted to forwarding the movement against infant mortality, tuberculosis and other preventable ills.

Additions to a Scottish University.—On April 23 the Prince of Wales formally opened the new buildings of the Glasgow University. The buildings are for the departments of physiology, materia medica, forensic medicine, public health and natural philosophy, and have cost between \$400,000 and \$350,000.

Stuttgart to Have a Club House for Physicians.—The will of the late professor of surgery at Stuttgart, Germany, leaves \$10,000 toward building a physicians' club house, \$3,000 to the medical mutual benefit society, and \$2,500 to one of the public hospitals. Prof. A. Burchhardt succumbed to intestinal cancer.

Official Title for von Leyden.—The title of Acting Privy Councillor (*Wirkl. Geh. Rath*) has been conferred on Prof. F. von Leyden of Berlin, with the title of "F. excellenz." This is the first time that a member of the profession representing internal medicine has had this title conferred on him by the Prussian authorities.

Smallpox Quarantine in France.—A quarantine has been declared against persons entering France from Metz and they are not allowed to pass unless they submit to vaccination. If the epidemic at Metz continues (7 cases were reported for the last week in March) absolute quarantine measures will be enforced it is announced.

Recrudescence of Plague in Australia.—For the seventh year in succession Sydney, New South Wales, has been visited with an epidemic of plague. The recurrences each year have varied in severity but this year the outbreak has been in the heart of the city and has proved a serious one. According to the

Australasian Medical Gazette, there is every prospect of in definite recurrences. So far 30 cases have occurred, with 9 deaths.

Free Lance Congress of French General Practitioners—This congress is a remarkable evidence of the active organization of the medical profession now going on in all countries. The general practitioners of France have felt for some time that their practical interests were not sufficiently regarded by the powers that be, not even by the physicians connected with the teaching forces of the universities. They are state institutions in France and as such are liable to the danger of falling into bureaucratic ruts. The protest has been growing more and more general, and on April 13 nearly 1,300 medical men from all over the country gathered at Paris to discuss the two burning subjects, "Reform in Medical Education," and the "Enforcement of the Free Choice of a Physician by the Injured." More bedside instruction was demanded, more teachers, more graduate courses, etc. It was shown that while Berlin has 62 professors and 107 privat docents for 1,192 students, Paris has only 73 professors for 3,000 students, and no privat docents. The subject of "Medical Education in Germany" was presented by Jayle, while Jarvis reviewed the field and present status of medical education in Great Britain, and Koenig described "Medical Education in the United States." The organization of a body of privat docents, outside the official faculty, and remunerated directly by the students, was discussed and steps taken in the matter. While the speakers all held up for admiration the methods of medical education in other countries and pointed out the defects in the present system in France, yet all agreed that clinical instruction in the French schools bears favorable comparison with the best elsewhere in Europe, only there is not enough of it. A number of professors took an active part in the proceedings.

LONDON LETTER.

(From our Regular Correspondent)

LONDON, April 20, 1907

Conferment of Unusual Honors by the King on His Medical Attendants

King Edward, whose appreciation of the medical profession is well known, has conferred a most unusual honor on Sir Frederick Treves and Sir Francis Laking in recognition of "their great skill and unremitting attention" during his dangerous illness in 1902, when the former operated on him for appendicitis. He has granted an "honorable augmentation" to their arms, which consists in the addition to their shields of one of the lions of the royal arms. An analogous augmentation of the Prince of Wales' feathers was granted to the late Sir William Gull for his services when the King was Prince of Wales and suffered from a dangerous attack of typhoid fever. But professional services appear never to have been recognized before by the incorporation of the royal arms with those of a physician or surgeon. For an instance of augmentation with the royal arms it is necessary to go back to the time of Charles II, who added certain items to the shields of the Percivals of Boscoble and to the Lanes, because members of these families were instrumental in saving his life after the battle of Worcester.

The Manifesto in Favor of Alcohol.

The controversial storm provoked by the manifesto in favor of the use of alcohol continues. The inner history of the document has been made public, and several of the distinguished signers do not appear to be satisfied with their position. It appears that the manifesto was got up by a Mr. Williams, a barrister and writer on economic subjects, but not in any way connected with the medical profession. Sir William Gowers, whose name added weight to the document, has declared that if it were presented to him to day he would not sign it. He complains that it has been twisted to justify anything, whereas, the essential point was to justify the use of alcohol in acute disease. He would not have signed it if he had known that it originated with the laity. Mr. Jonathan Hutchinson was under the impression that Mr. Williams was a physician when the manifesto was presented to him. However, it was sufficient for him that it had been signed by Sir William Gowers. Dr. Pre Smith and Sir Dree Duckworth and he agreed with them that people are beginning to consider alcohol a poison which is certainly not and that these extravagant views ought to be corrected. Sir Victor Horsley, who is one of the foremost advocates of teetotalism in the profession, speaking at a temperance meeting said that the medical profession asked four years ago that every child should be taught the principles of health and temperance. When he said the medical profession he added facetiously he did not mean "his 16 bon vivant friends" who had signed the manifesto.

The Epidemic of Cerebrospinal Fever

The epidemic still continues and has appeared in fresh centers and reappeared in places from which it had disappeared. In Belfast during the week ended April 16 there were 27 fresh cases, and 42 patients remained under treatment, the total number of cases now amounts to 283, with 177 deaths. Cases are now being reported from better class districts hitherto exempt from the disease. The deaths of three adults during the past few days has created a feeling of danger in the community. The first of these deaths was of Nurse McDonnell, who contracted the disease from a patient supposed to be suffering from pneumonia. Within 24 hours Constable Egan, a robust and athletic man, was stricken, and died after five hours' illness. A few hours later a man named Spence, while walking in the fashionable suburb of Ballinacorney was taken suddenly ill and died after a few hours while being conveyed home in an ambulance. In Scotland, during the week ended April 30, 30 deaths from the disease were registered in Glasgow, 8 in Edinburgh, 3 in Leith, 2 in Dundee, and one in Greenock. In Glasgow for the week ended April 12 there were 100 patients under treatment. Other cases have occurred in the surrounding towns. In England cases are reported from various parts of the country—Nuneaton in Warwickshire, Leamington and Gateshead in Northumberland and Leicester.

An Imperial Conference on Hygiene and Temperance

In order to stimulate general interest in the scientific teaching of hygiene and temperance as an integral basis of national education, and to bring before the country during the visit of the colonial premiers trustworthy information as to what is done in various parts of the empire a conference will convene on St. George's Day, April 23. Arrangements have been made for appointing educational experts to describe colonial systems of teaching the two subjects. Papers will also be read by continental scientists.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, April 13, 1907

Opening of a Plague Grave

During the process of laying a new street in the center of the city of Vienna a place was discovered which had apparently been a receptacle for refuse and house waste in olden times. The laborers were, however, rudely frightened by finding underneath the heaps of material several skeletons which were embedded in layers of lime. This at once suggested that the place had been used as a burial pit during the last epidemic of pestilence (1789) when 12 per cent of the inhabitants of Vienna fell victims to the disease. The epidemic lasted from March to November and it had become custom to inter the corpses in a layer of lime and clay, with a view of preventing further infection. The reopened pest cave was at once closed, and the men were subjected to an extensive disinfection. For scientific purposes particles of the clothes remnants, the soil and some dust from within the cave were taken to be examined bacteriologically. Although similar incidents have been reported in other places there is no instance known that in modern times an outbreak of pest has been traced to this source.

Prophylaxis Against Epidemic Meningitis

The board of hygiene in Vienna has recently issued an order to all district officers of health as well as a public notification dealing with the means of fighting the spread of meningitis, which during the last year has been epidemic throughout the empire. As the best means for prophylactic treatment the instillation of proevanase is recommended. This is a serum produced by the action of the bacillus proevaneus on certain tissues. Dr. Cehle, an assistant at the pediatric clinic of Vienna, has instituted extensive experiments with this substance and has found that the diplococci or rather meningococci, which are found so often in the mucous secretions of the nose and pharynx of persons suffering from cerebrospinal meningitis are destroyed within 48 hours if a few drops of the proevanase are placed on the mucosa of the nose. This new remedy is not an antitoxin but acts more like a disinfectant perhaps by influencing the mucosa in such a way that its secretion becomes antagonistic to the diplococci. In the order issued by the board it is recommended that every physician, nurse, relation or friend of the patient should submit themselves to the prophylactic treatment which is entirely devoid of danger and each physician is requested to submit his observations on this point to the board of health. The quantity of proevanase at disposal in Vienna is as yet rather small but in the Children's Hospital a laboratory has been fitted out with all the apparatus necessary for its production.

Pharmacology

Scientific Pharmacy Abroad Worthy of Imitation.

We have before us a pamphlet which we refer to American manufacturers of pharmaceuticals for their careful consideration. The pamphlet is entitled "Directions for the Examination of the Pharmaceutical Specialties E. Merck, Darmstadt." It has been prepared in response to a request of the German apothecary society, and contains descriptions of Merck's proprietary products. For each product the description states the chemical constitution, the physical properties, and the tests whereby the identity and purity of the product may be verified. American manufacturers could well afford to offer similar publications. Since physicians are beginning to realize that many products are not what they pretend to be, reputable manufacturers will no doubt court the investigation of their preparations. They can do this most effectually by placing at the disposal of those interested tests whereby the quality of their product may be verified.

MEDICINAL FOODS

Report of the Council on Pharmacy and Chemistry of the American Medical Association

The following report was submitted to the Council by the subcommittee which examined the medicinal foods:

To the Council on Pharmacy and Chemistry.—In order to determine the food value of any food product it is necessary to consider the following points: Chemical composition, available potential energy, absorbability and cost. No attempt is made in this article to discuss each of these features separately, but they are utilized as required.

The ingredients on which the food value of any article of food depends are the proteid substances, carbohydrates, fats, certain inorganic bodies and—under certain conditions—alcohol. The amount of each of these present in a preparation must be established by chemical analysis. From the results thus obtained it is possible to calculate the potential energy represented by a given food product. In this report the potential or food value is expressed in the large or kilo calories, that is, the amount of heat required to raise the temperature of one kilogram of water one degree centigrade.

Foods are more or less completely absorbed, and the total energy of some of the bodies absorbed is not completely utilized by the animal organism, because the oxidation of certain substances is incomplete. The factors employed in this report for expressing in

calories the actual amount of energy utilized by the system are 4.8 for proteid substances, 4.1 for carbohydrates, and 9.2 for fats. Various factors are employed for this purpose, for example, 4.23 for proteids of animal origin and 4.1 for proteids derived from a mixed diet, but the above are satisfactory for all practicable purposes.

The accompanying table embodies the results obtained by submitting all the well known so called "predigested foods" to chemical examination. In most cases two samples of the same brand were purchased at an interval of about six months. All the analyses were made before Jan. 1, 1907. Inasmuch as the chief object of this investigation is to ascertain the food value of the products under consideration, the figures represented by the first six columns will be passed over with this comment that some of the preparations contain much glycerin which does not, so far as known at present, possess any recognized food value, although there are a number of experiments on record to indicate that it influences metabolism.

The amount of inorganic material varies materially, from 0.18 to 1.61 per cent. It consists, so far as tested, of salts of sodium, potassium and calcium, and phosphates and chlorides.

The percentage of nitrogen accredited to each of these products represents the total amount of nitrogen, irrespective of the nature of the nitrogenous substances. This basis is giving the several preparations more value as food products than they actually represent, but inasmuch as it is difficult to ascertain how much of each nitrogen bearing substance present will be utilized by the system, the benefit of the doubt is given to the preparations, and the entire percentage of nitrogen present in each is made the basis of proteid contents. The proteid matter present in these foods consists largely of peptones and proteoses. The latter correspond to less advanced stages of hydrolysis than the former, but for dietetic purposes they may be regarded as of equal value.

By multiplying the percentage of nitrogen found by the factor 6.25 we obtain the percentage of nitrogenous matter (proteids) contained in the various preparations. It should be stated in this connection also that the factor 6.25 is probably a little too high. By using this factor the percentage of nitrogenous matter present in the several products investigated varies from the lowest, 0.43 per cent., to the highest, 6.38 per cent. By multiplying the number of grams of nitrogenous matter present in 500 grams of material by the factor 4.8 it is found that the potential energy available by the nitrogenous matter varies from 103 calories to 1531 calories. Five hundred grams of the material is made the basis of calculation because it approximates a pint, the amount usually believed to

TABULATED RESULTS OF

No.	Name of Preparation	Name of Manufacturer	Price per bottle	No. of Cc. in bottle	Cost per 500 Cc.	Reaction	Specific gravity	Per cent. non volatile residue	Glycerine and undetermined matter

*Total calories per diem dose includes the calories of alcohol in

be present in the various trade packages, and because it affords a ready basis of calculation.

There are no fatty substances present in these products, their food value from this point of view is, therefore, nil.

Another group of food constituents to be considered in these preparations is the carbohydrates. They are represented by cane sugar, maltose, dextrin and invert sugar. Lactose is probably also present in some, but it is impossible to establish this. The total amount of carbohydrates present is represented by the column headed "after inversion." By referring to these percentages it will be found that the variation ranges from 0.65 to 15.57. By multiplying the number of grams of carbohydrates present in 500 grams of the foods by the factor 4.1 we obtain the potential energy represented by the carbohydrate, which varies from 113 to 3192 calories. By adding together the total calories represented by 500 grams of the foods in question, of both the proteids and carbohydrates, we have a variation ranging from 547 to 3975 calories. The total food value of an equal quantity of milk, including fat, approximates 300 calories.

The value of alcohol in the hands of the physician is recognized by most practitioners and is frequently resorted to in severe cases of illness. Its value as a food product pure and simple in disease is, however, an open question. There is no doubt whatever but that it acts to a certain degree as a food even here, not as a tissue builder, but as a saver of fat and carbohydrate material, and in order to give the preparations in question full value as food products, the calories, represented by the alcohol, are credited to each preparation, as are the proteids and carbohydrates. The factor usually recognized for expressing the calorific value of alcohol is 7. The percentage of alcohol by weight present in the various preparations under consideration, varies from 12.0 to 18.8. By multiplying the number of grams of alcohol present in 500 grams of material by 7, the number of calories varies from 420 to 658.

On looking over the literature and printed matter distributed by some manufacturers, the physician is frequently left under the impression that these preparations contain all the essential constituents necessary for maintaining normal nutrition of the body, as is clearly shown by the following quotation: "Contains sufficient nutritive material to maintain normal nutrition of the body, a valuable food in typhoid fever, pneumonia, tuberculosis, and all the conditions of the system associated with enfeebled digestion and malnutrition."

In order to show the insidiousness of such representations it is only necessary to give the actual food

value of the average daily dose (the average amount to be taken for twenty-four hours) recommended by the various manufacturers for their products. The average adult daily dose recommended varies from 50 to 150 c.c. The total available calories per daily dose based on the proteid and carbohydrate bodies varies from 98 to 1105. Adding to these figures the amount of energy represented by the alcohol, in each case, the total available calories varies from 550 to 2995. The number of calories required *per diem* by a man doing very moderate work approximates 3,000. In sickness this amount is not required, but on the average it should not fall much below 1,500 calories during twenty-four hours.

In order to get a fair conception of the actual food value of these various preparations, it is desirable to make some comparison which can be readily comprehended by every physician. The amount of good milk necessary each twenty-four hours to sustain the vitality of a patient during a serious illness is not less than 64 ounces or approximately 2,000 c.c. The food value in calories represented by this amount of good milk may be placed at 1,430. This includes not only the proteid and carbohydrate matter, but the fat as well. By comparing this available potential energy with the total energy available in the predigested foods under consideration it can be readily seen that if a physician depends on the representations made by some of the manufacturers, and feeds his patient accordingly he is resorting to a starvation diet. The largest number of available calories, including alcohol, present in any of the recommended daily doses, is less than one-fifth of the number of calories represented by 2,000 c.c. of milk, and the calories represented by the daily dose of the preparation poorest in food products is only one-twenty-fifth of the amount present in 2,000 c.c. of milk. These figures tell their own story.

Making 2,000 c.c. of milk the basis of calculation and estimating the amount of the various preparations required to yield this number of calories it is found that the quantity to be administered daily to supply 1,430 calories including alcohol, varies from 716.2 to 1506.2 c.c. In other words, it will be necessary, in order to supply 1,430 units of energy *per diem*, to administer the amount of the various products in quantities found within the above limits. In many cases the amount of alcohol exhibited by these quantities would keep the patient in an alcoholic stupor continually. The cost necessary to supply this energy varies from \$1.48 down to \$3.30. Compare these prices with the cost of two quarts of milk. Is farther comment necessary?

The average number of calories represented by 500

grams of these products as proteids and carbohydrates is 260.6. The total average calorific value of the same amount of these foods is 802.4.

The number of calories represented by good brandies or whiskies, containing 45 per cent of alcohol, is 1,575. In other words, the average calorific value of these preparations is approximately one half that contained in either good brandy or whisky. From this it must not be concluded, however, that equal quantities of brandy or whisky are twice as valuable as the medicinal food because the medicinal foods contain some material which can be utilized in building tissue, which is not the case with either whisky or brandy.

From the above it can readily be seen that not only is the patient receiving a starvation diet when the physician resorts to these preparations, but that the unfortunate sick are also compelled to pay exorbitant prices for the amount of actual nutritive matter received.

It is urged in justification of the use of preparations of this class that they contain constituents not found in our ordinary foods and in a more perfectly assimilable condition. As pointed out above, these so-called predigested foods contain no fats, the carbohydrates in them are the ordinary sugars present in our common foods, while the proteins belong to the peptone or albumose class. It is for these latter that the greatest claims are made, but even here no value can be pointed out not found in whey, peptonized full milk or peptonized skimmed milk.

There is likewise another point of considerable importance to consider in this connection. The terms *peptone* and *albumose* include bodies of very uncertain composition, and their suitability as food substances depends largely on how they are prepared. Animal experiments have shown that nitrogen equilibrium may be maintained, for a time at least, by use of enzymic hydrolytic products of the proteins, even where the hydrolysis has been carried far beyond the so-called peptone stage, but it appears to be likewise true that the mixtures secured by acid or high temperature steam hydrolysis have no such value. Some of these, indeed, may exhibit a toxic behavior. This is true in particular of some of the commercial varieties of peptone, and until more is known of the source of the bodies of protein character employed in the make up of these "predigested" mixtures it is unwise to assume anything concerning the food value of the nitrogen compounds found in them by analysis or even to dignify them by the name of foods.

Your subcommittee makes the following recommendations:

1. No liquid medicinal or predigested food shall be approved by the Council which contains less nutritive value, exclusive of alcohol and glycerin, than milk.

2. At least one fourth of the nutritive value of the food, exclusive of alcohol and glycerin, shall reside in the nitrogenous matter.

3. The label shall bear a statement whether the peptones and proteoses are produced by enzymes or otherwise.

4. No package or advertising matter of any character shall bear representations which would lead the physician to believe that a food contains more nutrients than it actually does, or that it alone can sustain life for a limited period, if the dose advised contains less than 100 calories, exclusive of alcohol and glycerol, per diem dose.

5. Solid or partially evaporated products shall conform to the above standards when calculated to the water content of milk, viz. 88 per cent.

The report of the subcommittee was adopted by the Council and ordered published. W. A. PUCKNER, Secretary.

ANASARCIN AND ANEDEMINE

(Concluded from page 1536)

ANEDEMINE

If we are disposed to doubt the vaunted scientific ability of the Anasarcin Company, we are forced to admire their business methods, at least if there is any truth in the saying that imitation is the seal of success. Anasarcin has had this rather undesirable compliment paid to it for its

native town of Winchester has given birth to another remedy, Anedemine, which looks like a fair haired twin brother. The Anedemine Company has adopted Anasarcin almost bodily. The name—"opposed to edema"—is about as close as the copy right laws permit. The pharmacologic and therapeutic claims agree almost literally with those of Anasarcin and contain the same exaggerations and dangerous misstatements. There is the same emphasis on free purgation with Epsom salts. The dose is the same. Both are marketed at two dollars for a box of 100—only the Anedemine people have adopted the prize package device of throwing in 20 or 30 tablets extra, for good measure, and give a discount of 75 cents or so.

In short, the Anedemine Company has appropriated all of Anasarcin which they considered of any value. It is, therefore, rather suggestive that they drew the line at the formula. Anasarcin is said to contain squill, sambucus and oxydendron, Anedemine discards the oxydendron and reinforces the squill with strophanthus and apocynum. Notwithstanding this material change in composition, the actions are described as identical, this is again rather suggestive.

The Anedemine Company, like the Anasarcin Company, scorns crude drugs and claims to use only the isolated principles. It was saved the trouble of discovering active principles for strophanthus and apocynum, for these are known, but it managed to find some scope for its inventive genius, "both drugs being so chemically treated and disposed as to absolutely eliminate all objectionable and disagreeable properties and effects" so as to convert a vasoconstrictor action into a dilator action, so as to render them non toxic and non cumulative, so as to

Laboratory and Warehouse of the Anasarcin Chemical Company
Winchester, Penn.

deprive apocynum of its characteristic nauseant effect. Who can say that the days of miracles are past? Even this is not the limit of Anedemine alchemy, if we are to believe their claims, they have succeeded in forcing strophanthus, apocynum, scillain, etc., to combine with each other. "It is a definite chemical compound of the active principles" of these drugs! This makes the achievements of Emil Fischer in synthesizing sugars and proteids appear as mere child's play.

Since the formulas were completed, however, clinical reports have been numerous enough—almost too numerous, if we are to believe them. Anedemine has been on the market for less than three years, the circulars emphasize that testimonials and endorsements are not solicited. Nevertheless, we are told that it is "endorsed by over fifty thousand clinicians throughout the United States." Since the total number of physicians in the United States and Canada is only about 125,000 this means that nearly every second physician has endorsed Anedemine. The Anasarcin Company solicits endorsements and they seem to do the larger business. Hence the majority of physicians of the United States must have written an endorsement of either Anedemine or Anasarcin or both. Or is this statement another "invention"? It is a little peculiar that nearly all the endorsements come from small towns in sparsely settled districts, practically none from the centers of population. Does this mean that dropsy is more common in the rural communities than in the cities?

THE INVENTORS OF ANASARCIN AND ANEDEMINE

Even the newspapers, when they tax our credulity with pretended scientific "discoveries," feel the moral obligation of justifying themselves by telling us something of the personality and experience of the discoverers. We may ask, therefore, who are these expert pharmaceutical and synthetic chemists, these manufacturers of active principles, these skilled clinicians of wide experience, who have "intelligently built up the formula by wide application?" What are we told of these men who ask us to believe, on their mere assurance, in miracles and feats of magic, who tell us that they have converted neutral principles into alkaloids, that they have effected definite chemical compounds between these neutral principles, that they have discovered principles that do not exist, that they have changed the actions of these principles to suit their wishes, that, in short, they have reversed the laws of Nature?

These companies are located in Winchester, Tenn., a town of about 1,500 inhabitants, situated in an agricultural country. The town boasts of neither scientific schools, colleges, universities nor laboratories. The Anasarcin Company was organized in 1902, the incorporators and directors being Dr. John W. Grisard and his sons, Dr. John P. Grisard, B. A. Grisard, and A. F. Grisard, and Will W. Walker, all of Winchester. Dr. John W. Grisard seems to be the originator and promoter of Anasarcin. W. E. Walker is an insurance solicitor of Winchester and is not actively identified with the business. We are informed that he owns but a single share of stock having a face value of \$100, and that he was added to the company in order to comply with the laws of Tennessee, which require five directors for any corporation. Dr. John W. Grisard, the father, has practically retired, but still has a general supervising interest in the business. There is no regularly licensed pharmacist or chemist connected with the company. The office is in the rear of a jewelry store in the business part of Winchester and on the second floor above. According to our reporter, an office force of about ten stenographers and clerks handles the correspondence and labels and sends out the preparation which is made in a crude frame building located on a side street and without laboratory equipment. According to our reporter, the work is done by the Grisards and a colored man.

The Anedemin Chemical Company was organized in 1905 with a capital of \$20,000, the incorporators and directors being Dr. T. B. Anderton, Floyd Estill, J. J. Lynch, J. M. Littleton and I. G. Phillips, all residents of Winchester, and all lawyers with the exception of Dr. T. B. Anderton. A Mr. Gordon, a clerical employé of the company, is reported to have active charge of the business, to prepare the medicine and conduct the correspondence. The office headquarters, laboratory and complete outfit of the Anedemin Company comprises two rooms over the law office of Estill and Littleton. No one connected with the company is a regularly licensed pharmacist or graduate chemist.

Of the six physicians located in Winchester, three of them (50 per cent), are engaged in the dropsical cure business. Poor Winchester! Aside from their connection with these two nostrums, these physicians may be estimable and worthy citizens, but where, pray, did they find the extensive clinical facilities and pharmaceutical knowledge necessary for their wonderful and epoch-making discovery? Were they aided in their scientific work by the four lawyers connected with the Anedemin Company or by the insurance solicitor who is a director of the Anasarcin Company? Did the 1,500 inhabitants of the town furnish the vast clinical material necessary for discovering and working out the formulas of these two preparations? If so, we fear that dropsical affections are much more prevalent in Winchester than in any other known spot on the globe. This matter should be investigated. Without doubt the vital statistics of Franklin County would be most interesting and we commend them to the special attention of the medical profession in Tennessee.

Naming of Carbon Compounds.—Oxy indicates an oxid, thus either U. S., $\text{CH}_3\text{CH}_2\text{OCH}_3$, is ethane oxy-ethane. Often "oxy" is used to indicate hydroxyl, thus phenol is called oxybenzene, resorcinol of phenol is called dioxybenzene, etc.—*Pharm. Rev.*, September, 1906

Correspondence

The Adaptation of Clinical Methods to the Practicing Physician.

CHICAGO, April 24, 1907

To the Editor.—Some years ago I was desirous of studying clinically surgical work on a certain anatomic region of the body. Living in Chicago, where clinics in abundance in this department of practice, as in others, are accessible, the project seemed a very simple one. I tried, and to my surprise, found the plan impracticable. At the clinics attended for this one purpose there was presented a great variety of cases, which, not appealing to me then, merely served to consume my time. Thus I wasted hour on hour in order to get at even one case I wished to see. I gave up the idea then and I should have to give up such a project to day. It was not at that time and is not now practicable to expect a clinician to keep a score of men in mind and telephone them of the cases to appear at his clinics.

Thinking over the reason for my fruitless experience I came finally to understand the difficulty. Our clinical methods had their origin in the instruction of undergraduates, and they have never been altered to meet the widely different demands of the physician. The undergraduate knows little or nothing of medicine and, therefore, one case appeals to him with about as much interest as another. And this to a large but lesser extent is true also of those postgraduate students who are attempting to cover a field completely with which they are not familiar. And it is, to be sure, true also to a small extent of all physicians, especially when in a half serious mood. But the present clinical arrangements are such that the advantageous utilization by the mature physician of clinical facilities is almost an utter impossibility. The idea of adapting them to the practicing physician has never been worked out, or apparently never conceived.

What is chiefly needed is that the physician shall be enabled to select out of the whole number of cases to be presented in a particular city each day those capable of appealing to him at that time. This selective need is absolutely fundamental in the best mature study, for each individual mind possesses its own store of knowledge different from that of any other mind, and the need for adding to this store is all the time changing. It is this selective aid which makes the index to periodicals and books so valuable that without it education would, except for unusual minds, hardly advance beyond the rudiments. The failure of clinicians to recognize the fundamental value of this indexing principle is responsible for the comparative uselessness of clinical instruction to the physician. What is needed is that the physician shall be directed by a clinical index exactly where to go to satisfy his clinical needs, precisely as he goes to the book index for direction as to printed knowledge. And the evident fact that such an index could not be so perfect or so complete or so exactly applied as that for periodicals or books, does not practically affect the question. Usefulness, not perfection, is the stamp of practicalness.

This plan calls for the indexing of clinical cases of whatever character occurring in all the medical teaching institutions of each of our cities, especially the large clinical centers. To a certain extent it implies interference with the present strictly institutional plan of postgraduate study. If each postgraduate school be compared to a medical periodical the plan proposes not to confine the physician to one magazine, but to open them all before him and by means of an index allow him to read where he may derive most advantage. It represents a positive advance in our methods of medical study. What a tremendous aid it would be to the out of town physician to feel that he could at any time step over to a large clinical center and attend case after case exactly, or nearly exactly as his needs required instead, as now, of wasting most of his time on cases which only slightly appeal to him. The usefulness to the home physician of clinical instruction would be still more increased because his needs could be exactly fulfilled at any time. On the whole, attendance would be enormously stimu-

lated. The schools would doubtless adopt a uniform low price for each clinic attended.

It goes almost without saying that each clinical center should publish a permanent, frequently revised, schedule of its fixed clinics. This should be done whether the more important and more far reaching plan I am proposing is adopted or not. Such a schedule would be of great advantage especially to out of town physicians.

Granting it possible to index clinical instruction, what form would such an index assume? This instruction is transient, changing each day and completed each day. It must evidently be indexed daily. Each morning, then, a new index of that day's instruction is required. It must also be made readily and cheaply accessible to every medical man in the city. Is there a practical way of issuing such a daily clinical index? Undoubtedly there is. Two possible courses are available. The first necessity whichever plan is utilized is the establishment of a central editorial bureau to whom clinicians may telephone at the close of each day their clinical plans for the day following, so far as these can be foretold. The information may then be made known to the physicians, either (1) by answering telephonic inquiries only, or (2) by printing the material in the evening or night and either mailing it or distributing it by carrier, on the following morning. The first method is undesirable because its usefulness would be too limited. The second, if the distribution were directly to physicians, would possibly be too expensive to be completely practical. A compromise plan of distributing this daily clinical index to certain central stations easily accessible to all physicians (as for example, either all or certain drug stores), seems practical and easily carried out. Clinical plans which could not be foretold early enough for the publication, if sufficiently important, could be telephoned later, perhaps in the morning to the editorial bureau, there to be on telephonic demand when requested by physicians.

Who should bear the expense is a matter for consideration. It is possible that most drug stores would be glad to pay a fair subscription price for a periodical attracting physicians to their stores. It is possible also that certain schools might pay a proportion of the expense, at any rate through the way of advertising. It is certain that large numbers of physicians, especially those from out of town, would either buy copies (which should be on sale) as needed, or would subscribe for a longer or shorter period. At any rate, hundreds of physicians would manage to find means to consult such a clinical index if it existed. Advertising would help largely.

It is important that this project should be executed not by private enterprise, but by collective medical effort. In this way only can full cooperation be secured, and, especially, can objectionable advertising of clinicians be avoided. The names of clinicians should not appear in connection with their clinics. Which shall be the first of our cities to take this important advance step?

ELMER L. KENYON, M.D.

The Great American Fraud

ROGERSVILLE, TENN., April 10, 1907

To the Editor.—Undoubtedly untold benefit has resulted from the literature exposing the "patent medicine" fraud and the methods of the advertising quacks, but, unfortunately, the great body of the people who stand most in need of enlightenment have not been reached by these publications. High priced magazines, like *Collier's Weekly* and the *Ladies Home Journal*, do not reach those who live in the rural, and especially in the mountain, sections. Residents in the towns and cities buy the cure-alls and patronize the "quack specialist" to some extent, but nothing to compare with the former class. These are a simple people often remote from capable physicians, they rely on doctoring themselves making their diagnoses from advertising matter of "patent medicines." They see only a small amount of literature aside from the county paper, which comes to them weekly and the mass of nostrum advertisements brought by the R. F. D. man. All this literature is read with avidity. The weekly paper filled with fraudulent advertisements is read from top to bottom each week going over the same matter the medicine advertisements are looked on as

advice direct from the editor, a man of great veneration and learning. Many of these families are very poor, and often sell the last cow, their chickens and eggs (thus depriving them selves of the only proper food for the sick available to them), to raise money to send for a supply of "Dr. King's New Discovery for Consumption" or some one's "cancer cure."

Out of many cases I have witnessed permit me to mention two which recently came under my observation.

CASE 1.—In the latter part of May, 1906, I was sent for to amputate the breast of Mrs. M. T., aged about 55, who resided in this town. I found her in great agony. A cake of absorbent cotton covered the entire left breast, arm, side and back, down to the crest of the ilium. About three months prior to this time she had discovered a small, freely movable tumor about the size of a robin's egg in the left breast, it was not attended with pain or any discomfort. She became somewhat alarmed, and her sister, with whom she lived, found an advertisement in their religious paper of "Dr." D. M. Bye and his "Wonderful Oil Cure for Cancer." For many weeks prior to the time I saw her she had been using the "oil cure," with the result that all the skin and part of the flesh was burned off from the extensive region covered by the absorbent cotton, which had become converted into an extensive scab. (I see from one of his letters to her that the application of cotton was directed, and that in her case the "oil" had been somewhat modified, making it stronger.) The condition was septic in the highest degree, suppuration and absorption going on beneath the cake of cotton. I was able to remove the "dressing" by insinuating peroxid of hydrogen beneath it, the whole coming off in one solid mass. The wound had the appearance of a deep seated burn. The lump in the breast, I was informed, had undergone no perceptible change. The woman was in a pitiable condition and no operation was considered. She died from sepsis and exhaustion in two days after coming under my observation.

The little tumor, while probably malignant, was not a factor in her taking off, but death, in my opinion, was directly due to the corrosive applications made by direction of "Dr." Bye. It appeared that she had paid the Bye concern \$500, and at the time of her death a box of the "treatment" arrived at the express office, for which \$50 had been paid. The Bye concern refused to take it back or to allow the sister anything whatever for it, although they had guaranteed a cure. Removal of the growth was the only treatment that should have been considered in this case.

CASE 2.—Mrs. B., a widow, with several small children totally blind from absolute glaucoma, had been told by myself and other physicians that nothing whatever could be done to restore or in any manner to benefit her sight. She was written to by "Dr. Coffee Eye Specialist," who, without the least idea of the nature of her trouble, undertook to guarantee a perfect cure. The woman was very poor, but she managed to pay him \$8 a month for more than two years. When she could no longer raise the necessary amount, he reduced the fee to \$5, and this payment was kept up for many months, until it became utterly impossible for her to pay him anything whatever. He used the "absorption" method. His letters to this woman are before me and are cunning and ingenious. They explain in a graphic manner that a "membrum" has formed over the sight, and just as soon as his medicine "absorbs the growth" her vision will be as good as ever, that "vision would not return as long as there was a vestige of membrum," that the "membrum was growing thinner all the time," and that it would return very suddenly and that it would be disastrous to give up treatment that maybe one more application of his absorbent would have been sufficient.

Now, what I propose is that an effort be made to raise a fund sufficient to have the *Collier's Weekly* and *Ladies Home Journal* articles on "patent medicines" published in cheap pamphlet form for distribution among the people who can not be reached in the ordinary way. This would be the most vital blow that could be given this colossal fraud. Such a pamphlet would be read and passed from house to house. It would open up a side to this subject undreamed of by the people to whom I refer. It is almost a universal belief that these "patent medicine" establishments are the source of all medical and scientific knowledge that when medical students and physicians

go off to the city to study that Pierce's concern at Buffalo, N Y, or some other like concern is the great institution of learning the students attend

Yet it appears somewhat ironical that an organized effort should be necessary to save the fool from the consequences of his folly and to provide protection for the gullibility against which common sense should be a sufficient safeguard

J E MILLER, MD

[COMMENT—"The Great American Fraud" articles are published in pamphlet form by the American Medical Association with permission of *Collier's Weekly*. They make a pamphlet of 146 pages, with 65 illustrations, which is sold at less than cost (see advertising page 39, this issue), the object of the Association being to keep these articles in circulation. In this pamphlet both of the frauds mentioned by our correspondent are exposed

"Dr" Bye it is who, with the proceeds of his blood money, has established a church in Indianapolis. His "literature" oozes with piety. In it we find that "surely God's blessing attends the oil cure," which for blatant blasphemy would be difficult to equal. He was listed by Adams under the "cancer vampires"—a classification which seems peculiarly appropriate. "Dr" Coffee is also one of the "mail order" specialists. He has illustrated his "literature" with pictures stolen from Haab's "External Diseases of the Eye." These illustrations, with fabricated legends under them, are used to show what miraculous cures are wrought by the "Absorption Treatment as Originated and Perfected by Dr Coffee." Coffee is strongly endorsed by the editor of his local paper, Mr Adams wonders whether prompt payment for advertising space enters as an element into the testimonial

Appropos of the above, we quote the following from the *Ohio State Medical Journal* for April—Ed.]

"There is little doubt that the most effective weapon now in possession of the medical profession, with which to fight charlatany is the reprint from *Collier's Weekly*. Put this little book in the home of every man in the state and the problem of suppressing charlatany is solved. It impresses every reader with its truthfulness. It is an unanswerable document, showing that this traffic in drugs by pretenders to medical knowledge is, indeed and in fact, the Great American Fraud. What are we going to do about it? Shall we recline supinely and expect the people to run after this information? People are not consumed with anxious desire for this knowledge but they accept it if it is properly offered. Every society should order enough copies for the use of members and for public and private distribution. Secretaries of county societies should see that book sellers and news stands have them on sale. Libraries should be supplied and the reading public should find easy access to information which can not be obtained in any other way. It is not derogatory to professional dignity to engage in the work of rescue of the deluded and misled people. Members of the state legislature should have information on the questions contained in the reprint. If the profession is as zealous as the charlatans the work will prosper"

Teach the Public that Medical Practice Is More Than Drug-Giving

DODGE CITY, KAN., April 23, 1907

To the Editor—Will you permit a suggestion with regard to the fight against the nostrum industry? Much good has been done by Mr Bok and Mr Adams by their exposure of the conscienceless exploitation, by nostrum vendors, of human suffering. It is to be hoped that much reformation has been accomplished in medical ranks by the Council on Pharmacy and Chemistry and by medical writers on nostrums and the sins of physicians in prescribing nostrums. But in my opinion the keynote to success in the antinostrom fight has not been sounded. So long as we cling to the habit of prescribing something, whether the patient needs any drug or not, for the sake of holding his business, so long are we encouraging the delusion that the real value of the physician lies in the drugs that he gives regardless of the fact that at least nine tenths of his professional training is for the purpose of enabling him to ascertain the condition of the patient—to diagnose the case

When the laity realize this fact they will naturally and inevitably doubt their own ability in self diagnosis and will cease to buy the ready made "dope" that now cumbers the druggists' shelves. They will also cease to furnish remunerative employment for the long distance advertisers, and all the gentry who have a never failing cure for certain conditions.

Another thing which ought to be strongly impressed on the laity is that there is in every living organism a power that makes for health, that tends to restore the normal condition when it is overthrown—the *vis medicatrix naturæ* or the old writers. A proper appreciation of this fact will deprive the nostrum vendors of a vast amount of undeserved credit for cures. And if it be said that it will also deprive the attending physician of credit which would otherwise be given him, it is admitted. But is it not better to have the just appreciation of intelligent people than the undeserved adulation of the ignorant? The one will remain constant the other is proverbially fickle. The effect of such teaching on Christian science and similar fallacies can easily be foreseen and requires no comment.

To do this is not a light task, and it is not to be accomplished in a day, but it is necessary to the welfare of the people, and to furnish a proper soil for the development of our profession. How can it best be done?

Is it not naturally the work of the local medical society to educate the people of the neighborhood to a proper appreciation of a profession that concerns them so intimately as does that of medicine, not only individually but through newspapers and by other printed matter? If it be objected to this that we should be imitating the quacks, I can only answer that as long ago the churches decided that the devil should not have the best music so now it is surely time that the monopoly by quacks of the best means of disseminating information should cease. "Truth is mighty and must prevail" in a fair field. But if the truth is bottled up and not allowed to get into the open it is not surprising that falsehood scores a triumph.

Whether or not this public teaching be done, the duty of the physician to his patient is clear to give him the best service in his power, and then charge him a reasonable fee for it. But to hide a real service under a needless prescription is basely to prostitute the profession and to perpetuate the mental fog which envelops the public with reference to the practice of medicine.

The Book on Fractures by Lamb—An Explanation

BENTON HARBOR, MICH., April 13, 1907

To the Editor—In *THE JOURNAL* of April 13, 1907, p 1281, appears a letter from D S Lamb, Washington, D C, relative to letters coming to him from various parts of the country requesting copies of "New Methods of Reducing Fractures and Dislocations." I think I may be able to explain where Mr Lamb's letters came from, and why. A traveling contortionist gave an exhibition in this city about two years ago, and among other things, he told the physicians who were present that if they would write the curator of the National Medical Museum giving name, they could get gratis a book on new methods of reducing fractures and dislocations, published by the United States government. So far as I know no reply was ever received to the letter written from here.

FRED P BROWN

[Dr V M Griswold Fredonia, N Y sends similar information about the visit of this professional dislocator at Dunell, N Y—Ed.]

Miscellany

Investigations Concerning Nostrums in Germany—On several occasions *THE JOURNAL* has referred to the fact that the Pharmaceutical Institute of the University of Berlin is investigating the patented and other medicines exploited over there, in a way similar to the work being done by the Council on Pharmacy and Chemistry. In the *Apotheker Zeitung* Dec 22, 1906 are reported the recent investigations by J Krebs of the Pharmaceutical Institute, which indicate that in

which has been advertised as a ferrous saccharate, is in fact a mixture containing ferrous citrate with some ferric salt and sugar. In other words, it is not what it has been advertised to be. Kochs has also investigated grandira, a remedy for syphilis, advertised as containing 30 per cent. of calomel, but actually containing but 9 per cent. F. Zernik investigated aspiraphen, found that it is not amidophenacetin, acetyl salicylate, as claimed, but is a mixture of molecular proportions of free salicylic acid and monoacetylphenocoll. Zernik has also found that formurol is a mixture of about 37.5 per cent. of hexamethylenamin, with 62.5 per cent. of a mixture of neutral and acid sodium citrate. This preparation has been introduced as a remedy for gout and advertised as sodium hexamethylenamin citrate. The above named articles, so far as we know, are not yet advertised in this country.

The Doctor

The following poem was written by James Whitcomb Riley in memoriam of Dr. W. B. Fletcher of Indianapolis, (who died April 25) and was published in the Indianapolis *Morning Star* on the day of the funeral.

THE DOCTOR

*He took the suffering human race
He read each wound—each weakness clear—
And struck his finger on the place
And said 'Thouallest here!—and here!'*
—MATTHEW ARNOLD

We may idealize the chief of men—
Idealize the humblest citizen—
Idealize the ruler in his chair—
The poor man or the poorer millionaire
Idealize the soldier—sailor—or
The simple man of peace—at war with war—
The hero of the sword or life-and-death
Why not idealize the Doctor some?

The Doctor is by principle, we know
Opposed to sentiment—he tells all show
Of feeling and is proudest when he hides
The sympathy which natively abides
Within the stolid precepts of a soul
Which owns strict duty as its first control
And so must guard the ill lest worse may come
Why not idealize the Doctor some?

He is the master of emotions—he
Is likewise certain of that mastery—
Or dare he face contagion in its ire
Or scathing fever in its leaping fire?
He needs must smile upon the ghastly face
That yearns up toward him in that warded place
Where even the saint-like Sisters' lips grow dumb
Why not idealize the Doctor some?

He wisely hides his heart from you and me—
He hath grown fearless of necessity—
He knows the sight is clearer being blind
He knows the cruel knife is very kind
Ofttimes he must be pitiless for thought
Of the remembered wife or child he sought
To save through kindness that was overcome
Why not idealize the Doctor some?

Bear with him, prayerful in his darkest doubt
Of how the mystery of death comes out
He knows—he knows—are better yet than we
That out of Time must dawn Eternity
He knows his own compassion—what he would
Give in relief of all ills if he could
We wait alike one Master—He will come
Do we idealize the Doctor some?

—JAMES WHITCOMB RILEY

Home Treatment of Tuberculosis—B. R. Shurly, Detroit states, in the *Detroit Medical Journal*, that there are certain fundamental principles in the treatment of tuberculosis at home which must be omnipotent. The care by day and night of the infectious sputum requires the most constant attention to every detail. A newspaper cornucopia pinned to the mattress should receive the sputum rags or papers from the bedridden patient, and a destructible box or cup should be used by the ambulatory individual. If tuberculosis is to be limited the bacilli must be destroyed. Success of our methods requires the eternal vigilance of the attending physician. Among the intelligent the difficulties are appreciated and the value of sunshine, fresh air and disinfectants are readily understood. Among the uneducated element and in dispensary practice, it is necessary to resort to printed instructions to which frequent attention is called. It is Shurly's plan to place a member of the family in charge of the patient and to make him responsible for the proper management of the five fundamental principles of treatment. First, the de-

struction of the infective material, second, fresh air and sunshine in abundance, third, rest, fourth, pure food and drink to the limit of digestive capacity, fifth, the use of medicine as directed by the physician and in no other manner. This supervision is supplemented by visits at intervals of a trained nurse, who is especially instructed in the hygiene and care of the consumptive. The ingenuity of the physician alone can direct the proper method of supplying the greatest amount of sunshine and fresh air to the patient. The problems of fresh air supply, diet and rest, especially during fever, must be worked out for the individual along the lines of the fundamental principles and carried out with the persistence of a general. The fight of the consumptive for life is an uphill battle that requires masterful management and peculiar mental characteristics on the part of the physician. Treatment by suggestion is an extremely important factor in the cure of tuberculosis. Nature has endowed the patient with a great degree of hopefulness. This confidence in the power and judgment of the physician is a valuable factor in treatment. A buoyant spirit of pugnaciousness is an unfailing inspiration that frequently turns the tide of battle.

Treatment of Pseudarthrosis and Tardy Callus Formation by Injection of Blood—More than two years have elapsed since Bier first called attention to the value of local injection of human venous blood as a means to hasten consolidation. V. Schmieden, assistant at his clinic, reviews the experiences to date with the method in a communication to the *Med. Klinik*, III, 197, 1907. He remarks that the improvement in late years in the treatment of fractures has rendered pseudarthrosis very rare. This and delayed callus formation are observed only in persons who seem to be incapable of production of callus and in whom fractures seem unable to heal. In such patients the method of local injection of about 25 cc. of their own or foreign human venous blood seems to have a remarkable stimulating effect. He advises the simple intervention in every case of delay in the production of callus, without waiting for the development of a pseudarthrosis, and relates the histories of a later series of 11 cases which show the prompt benefits derived. A syringe is used that exerts considerable pressure, the piston being moved by a thumb screw and ratchet. In many instances the benefit was not apparent until after the fifth or sixth injection. He makes an injection every eight or ten days, and then waits to observe the results. Foreign human blood seems to be more efficient than the patient's own blood, and the effect is better when the blood is aspirated into the syringe and injected without further manipulation. A violent reaction ensues, with all the symptoms of acute inflammation, but it soon subsides, generally in the course of a day.

Nervous Phenomena in Children Due to Drinking Too Much Water—Millon comments on the habit which some children acquire of drinking large amounts of fluids during and between meals and at night. He adds that even in adults this habit of drinking copiously is easily established and soon becomes imperious. A man who is very thirsty during the first hot days of summer and drinks constantly, condemns himself to keep on drinking copiously all through the season. No one notices how much a child drinks, and by the age of 10 or 12 the habit may become actual potomania, causing the ingestion of 5 or 6 quarts of water a day. This excess causes dilatation of the stomach, but there is no vomiting nor eructations nor cutaneous phenomena, the symptoms being generally exclusively of a nervous order. Headaches, restless sleep, bad dreams and even insomnia are frequently encountered in children who overdrink in this way. The child wakes with a frontal headache which may persist at times for days and weeks. The character suffers from the returning headaches and lack of normal sleep. The disturbances may be the result of irritation of the sympathetic from distension of the stomach by the large amounts of fluid ingested. The dilatation of the stomach is not permanent, and all disturbances are soon corrected when the physician and parents succeed in restricting the ingestion of fluids within normal bounds. Millon's article was published in the *Gaz. d. Med. Infant*, VIII, 113, 1906.

Cure of Chronic Albuminuria by Intercurrent Scarlet Fever—Gillet reports the case of a child of about 8 left with in termittent, orthostatic albuminuria after an attack of acute primary nephritis with anasarca, fever and much albuminuria. After 4 years of this albuminuria, scarlet fever supervened, and the child was kept constantly in bed. On recovery from the scarlet fever the urine was re examined 109 times in the course of the following five years, but no traces of albumin or other signs of nephritis were ever discovered. Le Gendre, he adds, has reported a similar case, and Siredey one in which the albuminuria vanished after malarial infection. Gillet suggests that these paradoxical cures of albuminuria after an intercurrent infection possibly point the way to a new mode of treatment. His article is published in the *Gaz. d. Med. Infant*, vol. 33, 1906.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION CONTRACT PRACTICE INSURANCE FEES MEDICAL LEGISLATION, ETC.

Pennsylvania Osteopathy Bill Vetoes

Governor Stuart of Pennsylvania has vetoed the Wickersham bill, which was passed by both houses of the legislature. This bill provided for the organization of a separate board of osteopathic examiners and also for the appointment of an osteopath on the state medical board. Governor Stuart's message should be carefully read, as it contains some eminently sensible and clear cut statements regarding the recognition of osteopaths. He says:

"That the skilful practice of osteopathy has benefited the afflicted and alleviated human suffering in many instances is an established fact. It can, however, be practiced without violating the present medical practice act. No legislation, therefore, is necessary to permit osteopaths to practice their profession, but there is a broad and clearly defined distinction between practicing medicine and surgery and practicing osteopathy. The state is not concerned with any controversy between the different schools or sects and those who practice the art of healing but it is interested in protecting the public from incompetent practitioners of every sort. Whether classifying osteopaths, who are not physicians or surgeons, with physicians and surgeons, in legislation originally designed to be applicable only to physicians and surgeons would afford any protection to the public is considered doubtful."

The governor concludes by stating that while the regulation of osteopathy may be desirable it should be provided for by legislation other than amendments to a law intended to apply only to the regulation of the practice of medicine and surgery.

Medical Legislation.

An important amendment to the medical practice act has been adopted in Delaware. The principal feature is the adoption of a definition of medical practice, which includes Eddivism, mental healing, osteopathy and all the latter day fads. In Texas, after a prolonged struggle, the one board bill has been adopted and signed by the governor. Abstracts of these two laws are presented herewith.

DELAWARE

The legislature has passed an act amending the medical practice act adopted in 1895 and amended in 1899. The present amendment adds a provision that applicants who graduated prior to July 1, 1901, and who have been in continuous practice for at least five years since graduation may be admitted to examination on evidence of having completed three courses of medical lectures in different calendar years and of a competent academic education according to the requirements of that time. Applicants who graduated prior to July 1, 1896, and who have been in continuous and reputable practice for at least ten years may be admitted to examination on furnishing evidence of having attended two courses of medical lectures in different calendar years and of a compe-

tent academic education according to the requirements of the time of graduation. All other applicants must have pursued the study of medicine for at least four years and must present a diploma from some reputable literary or scientific college or a certificate from the faculty of Delaware College saying that the applicant is qualified to enter the freshman class of the Latin scientific course of the college.

Section 14 is amended by adding a provision for a temporary license of not less than two weeks nor more than four months, which may be granted to a resident and legally qualified physician of another state who desires to take charge of the practice of a legally qualified resident physician of Delaware during the latter's temporary illness or absence from the state.

In addition, two new sections are added. Section 20 defines the practice of medicine to be the opening of an office for the purpose of practicing medicine and surgery or the announcing to the public or to any individual in any way of a desire, willingness or readiness to treat the sick and afflicted in any county in the state of Delaware, or to investigate or diagnose or offer to diagnose any physical or mental ailment or disease of any person or to give surgical assistance or to suggest, recommend, prescribe or direct for the use of any person any drug, medicine, appliance or other agency whether material or not material, for the cure, relief or palliation of any ailment or disease of the mind or body, or for the cure or relief of any wound, fracture, bodily injury or deformity, or the receiving, either directly or indirectly, of any money, gift or other form of compensation for such services, or the use in connection with one's name of the words or letters "Dr.," "Doctor," "Professor," "M.D.," "M.B.," or "Healer," or any other designation which may imply or designate that the individual is a practitioner of medicine or surgery.

The usual exemptions are added regarding the administration of household or family remedies, dentists or dentistry, surgeons, surgeons of government services, or mechanical fitting of glasses, druggists practicing pharmacy, the treatment of corns or bunions, manicuring or massage.

Section 21 provides that any practitioner of osteopathy now engaged in the practice in the State of Delaware, who holds a diploma from a legally chartered school of osteopathy and who has attended at least four terms of instruction of not less than five months each, is exempt from the provisions of the act, but that all other persons shall be examined by the medical council with the assistance of a reputable practitioner of osteopathy.

TEXAS

The state legislature has passed the one board bill, and it has been signed by the governor, to become effective on July 1. This law provides for the establishment of a board of medical examiners to consist of eleven men, legal and active practitioners of medicine in the state who have practiced medicine under a diploma from a legal and reputable college of medicine for at least three years. No school shall have a majority representation. The board is to be appointed by the governor within ninety days after the act becomes effective and biennially thereafter within ninety days after his inauguration. The term of office to be two years. No member of the board shall be a stockholder, trustee or member of the faculty of any medical school. Certificates issued by the board are to be registered in the district clerk's office of the county in which the physician resides. In case of removal to another county, the individual must register in the office of the county clerk in his new location. District clerks are required to keep a record of all certificates recorded and to furnish a correct list of all the physicians registered in the county on the first day of January of each year. All local practitioners of medicine in the state are required to present to the board of medical examiners evidence to establish their right to practice medicine in the state. All other applicants must pass an examination before the board. Reputable medical schools are defined as those whose restrictions, requirements and courses of instruction are as high as those adopted by the better class of medical schools of the United States, whose courses of instruction comprise not less than four terms of five months each. Examinations shall be conducted on and

omy, physiology, chemistry, histology, pathology, bacteriology, physical diagnosis, surgery, obstetrics, gynecology, hygiene and medical jurisprudence. Dentists, nurses, masseurs, medical officers of government service and physicians of other states called in consultation are exempt. The board is authorized to refuse examination or a certificate for any of the following causes: Presentation of any license, certificate or diploma illegally or fraudulently obtained, fraud or deception in passing examination, conviction of a crime of the grade of a felony or one which involves moral turpitude, procuring, aiding or abetting a criminal abortion, gross unprofessional conduct of a character likely to deceive or defraud the public, habits of intemperance or drug addiction calculated to endanger the lives of patients. The courts are authorized to revoke any license for any of the above reasons. The practice of medicine is defined to be professing to be a physician or surgeon, treating or offering to treat any disease or disorder, mental or physical deformity or injury by any system of medicine, treating or offering to treat any disease or disorder and charging therefor directly or indirectly.

The new law is a great improvement over the old one, in that it provides for a general reregistration of all physicians a measure greatly needed, owing to the confusion resulting from four successive practice acts in the last twenty years. It also substitutes a single board and a single standard for the triple board system formerly in vogue. This is in line with the present tendency to substitute single, non-sectarian boards for multiple sectarian systems. The provision for an examination in the essential and fundamental subjects to the exclusion of therapeutics is also wise. The sooner the public realizes that a physician's preparation and training are of more importance than the "school" to which he may belong, the better for the public and for the profession as well.

A Timely Criticism.

In the *Journal of the Medical Society of New Jersey* for April appears an article by Dr. Luther Halsey of Williams town, of more than ordinary interest. One paragraph, in particular, contains both a criticism and a suggestion which is most pertinent at the present time. Speaking of the attitude of the medical profession toward state legislation in the past, Dr. Halsey says:

Our efforts however have been to a great extent poorly generated, disconcerted and spasmodic in character with no definite plan for action common to any two states and frequently even in the same state we find each succeeding legislative committee totally disregarding the work and plans of its predecessor. What the profession needs and what it must have before there can be uniform ideas regarding medical legislation and concerted definite plans of action is a deliberative meeting at which to discuss and agree on the proper principles underlying the several essential features of a medical law. Such a body should be made up of at least one representative of each state and territory and should hold a session of several days. It takes time and deliberate thought to accomplish anything along these lines and the sooner the profession realizes the necessity of tackling these problems in the proper manner the sooner we may expect success to crown our efforts.

Dr. Halsey has described a condition which must be apparent to all who have been working or thinking along these lines. Legislatures have been in session this winter in 30 states. In 26 of these, bills have been introduced which in some manner affect the legal provisions of medical practice. In states which have three examining boards, bills providing for a single board have been introduced. In states which have but one board or in which the board of health is the examining body, efforts are being made to secure the passage of a law establishing more boards. In some states the medical profession is advocating a single board. In other states it is advocating more than one. The experience of physicians who have been successful in obtaining desirable legislation in one state should be utilized by those working for similar legislation in other states. Arguments and methods which have been successfully used to defeat pernicious legislation in one state should be utilized for the same purpose in another. The experience of the profession in one state should be made available in others. The osteopaths are systematically working to secure the adoption of uniform laws in all states. Their success so far is due to the fact that the work has been directed from a central bureau and that all of their experience and influence has been focused on a single state at a time. The

organized profession ought to show at least the same amount of shrewdness and sagacity in securing desirable legislation for the good of the public that the Proprietary Association, osteopaths and other private interests show in obtaining legislation for personal reasons.

Insurance Resolutions

The following societies have adopted resolutions on the insurance question since the last list was published in THE JOURNAL.

Fort Wayne (Ind.) Medical Society
Norfolk South District (Mass.) Medical Society
Pima County (Ariz.) Medical Society
Somerset County (Md.) Medical Society
Medical Society of the City and County of Denver (Colo.)
Fayette County (Tex.) Medical Society
Kossuth County (Iowa) Medical Society
Franklin County (Pa.) Medical Society
Adams County (Miss.) Medical Society
Washington County (Wis.) Medical Society
Columbia County (Wis.) Medical Society
Fairfield County (S. C.) Medical Society
Scott County (Ind.) Medical Society
Northwest District (N. D.) Medical Society

The Public Service

Army Changes

Memorandum of changes of stations and duties of medical officers for the week ending May 4, 1907.

Wilson, James S., asst. surgeon, granted twenty-five days leave of absence.

Keller, William L., asst. surgeon, granted three months leave of absence with permission to go beyond the sea.

Howard, Deane C., surgeon, promoted to major and surgeon U. S. Army to rank as such from April 24, 1907.

Whitmore, Eugene R., asst. surgeon, granted ten days leave of absence to take effect on being relieved from duty at Fort Jay, N. Y.

Banister, John M., deputy surgeon general, Gandy, Charles M., professor of military hygiene, and Mason, Charles F., surgeon, appointed members of a board of medical officers to meet at West Point, N. Y., on May 20, 1907, for the purpose of making the physical examination of cadets required by Par. 25 of the General Regulations as amended by G. O. 74, April 13, 1906, War Department.

Brechemin, Louis, deputy surgeon general, granted three months leave of absence with permission to go beyond the sea.

Wyeth, M. C., surgeon, ordered to proceed to Hot Springs, Ark., and report in person to the commanding officer, Army and Navy General Hospital, at that place for observation and treatment.

Shaw, Herbert G., asst. surgeon, relieved from duty at Army General Hospital, Presidio, San Francisco, and ordered to Vancouver Barracks, Wash., for duty.

Gray, William W., deputy surgeon general, granted ten days leave of absence.

Robbins, Chandler P., asst. surgeon, granted fourteen days leave of absence.

Hughes, Leonard S., contract surgeon, relieved from duty at the depot of recruits and casuals, Angel Island, Cal., and ordered to Fort McDowell, Cal., for duty.

Koyle, Fred T., contract surgeon, relieved from duty at Fort McDowell, Cal., and ordered to the Presidio of San Francisco for duty.

Whitney, Walter, contract surgeon, ordered from Fort Preble, Me., to Fort Wadsworth, N. Y., for temporary duty.

Pingard, Joseph, contract surgeon, granted sick leave of absence for two months.

Kelly, John P., contract surgeon, ordered to accompany Troop F, Fourteenth Cavalry, to duty in the Sequoia and General Grant National Parks, Cal.

Hereford, John R., contract surgeon, ordered from Fort Dade, Fla., to Fort Fremont, S. C., for temporary duty.

Slater, Ernest F., contract surgeon, returned to duty at Fort Banks, Mass., from leave of absence.

Mount, James R., contract surgeon, ordered to duty with field artillery from Presidio of San Francisco, Cal., on target practice.

Richardson, W. H., contract surgeon, left Fort Sheridan, Ill., with troops for San Francisco.

Woolley, Herbert C., contract surgeon, ordered to Fort Liscomb, Alaska, for duty on Delta Gakona Cut-off, U. S. Military Telegraph Line, and then to duty at Fort Gibbon, Alaska.

Stephenson, Andrew V., contract surgeon, ordered to Presidio of San Francisco for duty.

Bell, Richard P., contract surgeon, relieved from duty on the transport *Albatross* and ordered to duty at Fort Leavenworth, Mo.

Wren, Raphael J., contract surgeon, relieved from duty at Fort Totten, N. Y., and ordered to Fort Slocum, N. Y., for duty.

O'Day, Sylvester F., contract surgeon, ordered to Fort Totten, N. Y., for duty.

Wing, Franklin F., dental surgeon, left Fort D. A. Russell, Wyo., for duty at Fort Meade, S. Dak.

Wolven, F. Homer, dental surgeon, relieved from duty at Fort Hamilton, N. Y., and ordered to Fort Niagara, N. Y., for duty.

Milikin, John D., dental surgeon, granted sick leave of absence for two months.

Navy Changes

Changes in the medical corps U. S. Navy for the week ending May 4, 1907.

A. H. Allen, asst. surgeon, to duty at Lajas, Cuba.

C. H. DeLancy, passed asst. surgeon, when discharged from treatment at the Naval Medical School Hospital, Washington, D. C., ordered to Navy Yard, Washington, D. C.

T. N. Phillips, pharmacist, detached from the Naval Hospital, New Port Lyon, Colo., and ordered to the Naval Medical School Hospital, Washington, D. C., for treatment.

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended May 1 1907.

Carrington, P. M., surgeon, granted leave of absence for three days from April 20 1907, under paragraph 189 of the Service Regulations.
Matthewson, H. S. P. A., surgeon, granted leave of absence for fifteen days from April 27, 1907.
Gribbs, S. B., P. A., surgeon, granted one day's leave of absence, May 6, 1907.
Holt, John M., P. A., surgeon, granted leave of absence for two months from June 20 1907.
Ward, W. K., asst.-surgeon, leave of absence granted for one month on account of sickness, from April 1, 1907, amended to read for twenty-two days only.
Stiles, Charles W., Chief of Division of Zoology, granted leave of absence for five days in April 1907.
Kastle, J. H., Chief of the Division of Chemistry, granted leave of absence for nine days in April 1907.
Schwartz, Louis, acting assistant surgeon, granted leave of absence for seven days from May 2 1907.
Straw, E. E., acting assistant surgeon, granted leave of absence for twenty days from April 16, 1907.
Ryder, L. W., pharmacist, granted leave of absence for seven days from April 27 1907.
Watters, M. H., pharmacist, leave of absence granted from April 1 1907, for thirty days, amended to read nineteen days from April 4, 1907.

BOARD CONVENED

A board of medical officers was to meet at Philadelphia April 30 1907 for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Surgeon J. M. Gassaway, chairman; Passed Assistant Surgeon T. Clark, Recorder.

Health Reports

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service during the week ended May 3 1907.

SMALLPOX—UNITED STATES

California: San Francisco, April 13-20, 1 case.
Illinois: Belleville, April 13-20, 1 case; Chicago, April 20-27, 1 case.
Kentucky: Louisville, April 18-25, 2 cases.
Massachusetts: Haverhill, March 9-16, 1 case.
Michigan: Detroit, March 20-27, 8 cases.
New Jersey: Hoboken, April 18-25, 1 case.
Ohio: Cincinnati, April 19-26, 1 case.
Texas: Houston, April 13-20, 10 cases.
Washington: Aberdeen, April 17, 4 cases; Spokane, April 13-20, 10 cases; Tacoma, April 13-20, 3 cases.

SMALLPOX—INSULAR

Philippine Islands: Manila, March 9-16, 1 case.

SMALLPOX—FOREIGN

Africa: Algiers, March 1-31, 8 deaths.
Austria: Trieste, March 30-April 6, 2 cases, 1 death.
Brazil: Para, March 30-April 6, 5 cases, 3 deaths.
Canada: Pictou County, April 20, present; Vancouver, April 13-20, 2 cases; Winnipeg, April 13-20, 2 cases.
Chile: Coquimbo, March 30, 6 cases, 3 deaths.

Chile: Antofagasta, March 30, 16 cases, 5 deaths; Iquique, March 30, present; Santiago, March 14, present; Valparaiso, March 14, present.
India: General, March 10-23, 0 cases, 53,000 deaths; Calcutta, March 10-23, 94 deaths.

Queries and Minor Notes

COFFEE ANEMIA AND DECAYED TEETH AND PNEUMONIA

WASHINGTON, D. C. April 29 1907.

To the Editor.—In the *Review of Periodics* for April it is stated (p. 435) that a child in a New York public school was found by a medical inspector to be anemic from the excessive use of coffee. 1. What authority is there for the opinion that this beverage could cause anemia and how much would be required to produce the effect? 2. Since the pneumococcus is present in the mouth, why is it not a reasonable supposition that pneumonia may be caused by the pneumococcus entering the lymphatics through decayed teeth?

ANSWER.—1. Authorities on pharmacology and toxicology present no facts to justify the opinion that anemia can be the result of a specific action of coffee. By deranging digestion favoring intestinal putrefaction or taking the place of a considerable amount of nutritive food, an excessive use of coffee may contribute to the production of an anemic state.

2. It is generally believed that pneumonia is usually a primary localization of the bacteria in the lung with secondary bacteremia. It is probable that in some cases the bacteria may gain access to the blood through the lymphatics and settle in the lungs as a secondary localization from the blood. As invasion of the lymphatics through the teeth would be slow, it seems improbable that a general bacteremia could arise in this way. Virulent pneumococci are pyogenic and would be likely to give rise to purulent lymphadenitis. The suggestion of our correspondent, however, deserves the attention of pathologists.

THE USE OF DENATURED ALCOHOL IN MEDICINE

MR. HORE, Wis. May 1 1907.

To the Editor.—Will you state through your columns the chemical and physiologic properties of denatured alcohol and also whether it is suitable for the making of tinctures and for other medicinal purposes?

D. C. MILLER, M.D.

ANSWER.—For the purpose of denaturing alcohol the law authorizes the addition of various specified substances the intent being to render the liquid unpalatable and undrinkable. Among these substances are gasoline and methyl alcohol. It is evident that the chemical and physiologic properties of the mixture would vary with the ingredient added. As the ingredients used are generally poisonous and in some cases more so than ethyl alcohol, the use of denatured alcohol for making tinctures would be not only illegal but dangerous.

WANTS REPORT OF MIKULICZ'S CLINIC

DR. C. E. PURCELL, Paducah, Ky., asks for an English translation of the report of Mikulicz's clinic, which was abstracted in THE JOURNAL, March 23 1907, page 1070, paragraph 60. This copy of the *Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie*, Vienna, costs \$10.00 and the article referred to occupies 64 pages, so it will be expensive for Dr. Purcell to pay for having the translation made. Perhaps some of our readers can refer him to a translation.

Association News

ATLANTIC CITY SESSION

Special Tickets May Be Purchased May 30 in Central Territory

Last week's issue of THE JOURNAL was the Atlantic City Number giving the programs of the sections, railroad rates, lists of hotels, meeting places and all other obtainable information concerning the approaching fifty-eighth annual session of the American Medical Association, to be held at Atlantic City, N. J., June 4 to 7, 1907.

The dates on which tickets are good for the going trip from Central Passenger Association territory has been enlarged by the addition of Friday, May 30, so that tickets are now sold May 30 to June 3. In New England territory tickets are sold May 31 to June 4. As stated last week, the rate is one fare plus \$1 for the round trip. Return may be made from June 4 to 10, or by deposit of ticket, departure may be delayed till June 18. Similar tickets are sold from transcontinental points May 25 to 27 and are good for 90 days. There are other tickets, sold May 20 and 21, from California to the eastern gate of transcontinental territory at one fare for the round trip. These have been furnished to particulars.

A Proposed Exhibition of Official and Open Formula Preparations

The Philadelphia Branch of the American Pharmaceutical Association has arranged to hold an exhibition of official and open formula preparations in the Exhibit Hall at the coming session of the American Medical Association at Atlantic City. This exhibition is intended to illustrate the resources and the possibilities of official remedies and to show the kind of work and the nature of the preparations that physicians can obtain from pharmacists. The art as well as the science of pharmacy, largely perhaps through our own lack of interest in how we were being served, has been much neglected by far the greater majority of what have become to be known as retail druggists, who, to enlarge on their perhaps meager profits, have helped to develop the "patent medicine" business.

NEW MEMBERS

List of new members of the American Medical Association for the month of April, 1907

ALABAMA.

Black, R. E., Tuscaloosa.
Cocke, N. P., Birmingham.

NEW YORK ACADEMY OF MEDICINE

Regular Meeting of the Section on Surgery, held April 5, 1907

Dr JOHN F ERDMANN, in the Chair

Operation for Habitual Dislocation of Patella

Dr. WILLIAM C LUSK presented a man, 41 years old, who, six years previous, while running slipped on some ice and fell over backward, dislocating both his patellae outward. After ward, always on flexion of the legs, the patellae slipped out ward over the external condyles. The right knee was operated on by modification of Krogus' method. Krogus divided the aponeurotic structures down to the capsule of the joint along the outer side of the patella, and the ilio tibial band above, to relieve the shortened tissues on the outside of the joint. Then making a musculo aponeurotic flap on the inner side of the joint without entering the joint on this side either, he carried this flap in front of the quadriceps extensor tendon around the upper border of the patella and laid the extremity of it in the wound which had been made in the aponeurotic structures at the outer side of the joint, and sowed it there. Then the edges of the wound at the inner side of the joint, made by the removal of the musculo aponeurotic flap, were sutured together, thus shortening to this extent the tissues at the inner side of the patella, by the support tendency to outward dislocation would be incision at the outer and through the muscle

fibers of the vastus externus to the outer edge of the quadriceps extensor tendon. Finding furthermore, that by Krogius' method only the tip of the musculo aponeurotic flap would reach into the wound in the divided structures at the outer side of the joint, instead of carrying this flap in front of the quadriceps extensor tendon, he made a blunt dissection beneath the tendon above the subquadriceptal bursa and carried the flap through the opening thus made and then laid it in the musculo aponeurotic wound at the outer side of the knee-joint, which was found to fit accurately from its upper limit down to within half an inch of its lower end. The flap was sutured in place with chromic gut. Operation was performed on January 14. On March 12 the patient gave up the use of his cane. On April 5 he had voluntary flexion of the right leg to 90° and forced flexion of about another 10°.

Fracture of the Patella.

DR. CLARENCE A. McWILLIAMS presented a man who fell and fractured his patella in five or six places. He prefers the transverse rather than the vertical incision, because it allows the lateral tears in the vasti expansion to be sutured. Three loose pieces of bone were removed, and a purse-string suture was placed around the remaining fragments. The man made a good recovery.

DISCUSSION

DR. HOWARD LILIENTHAL said that in the ordinary transverse fractures of the patella he has been in the habit of using the massage treatment. In this non operative treatment the patient was out of bed, but in splints, on the eighth day, and a cure is accomplished on the forty eighth day. King Edward's fractured patella was not sutured and yet good results were obtained. In cases of comminuted fracture, however, operation is proper.

DR. JOHN M. ERDMANN asked Dr. Lilienthal what he does to bring the fragments together in this massage treatment.

DR. LILIENTHAL replied that he first places an arrangement of tapes above and below the patella, strapping the fragments together, and an ordinary bandage is then applied. During massage however, everything is removed and the fragments are held in place by an assistant. Massage is given for fifteen minutes morning and night. By the eighth day it is supposed that adhesions have taken place which will hold the fragments together, and then the patient is permitted to get up, but with the splints on.

Drainage in Operations on the Biliary System

DR. HOWARD LILIENTHAL summed up the vital points as follows: (1) That the scientific and judicious employment of preliminary drainage in obstructive jaundice would probably lessen the dangers of such steps as might be necessary for permanent cure. (2) That the drainage should form the sole object of the surgeon's work until the factor of cholemia had become eliminated. (3) That radical operations should, in most chronic cases be postponed until hepatic engorgement and icterus no longer existed.

DR. A. V. MOSCOWITZ said he has never been a believer in hepatic drainage. In all cases requiring drainage, if the common duct is not free, no operation is complete until the duct is made free, if it is free, there is then sufficient drainage into the intestine.

DR. LILIENTHAL emphasized the importance of draining the liver through the gall bladder by a slow method.

New Operation for Cystocele in Women

DR. J. RIDDLE GOFFET's plan is to dissect away the bladder, freeing it entirely from all structures, except those above. He then rotates this viscus on its transverse axis, carries it up and stitches it to the uterus. The work is all done per vaginam. He has had from 50 to 60 cases under observation and he had not learned of a recurrence.

Surgical Anatomy of the Esophagus

DR. CHAS. R. L. PUTNAM showed the caliber of the esophagus differs in various parts. He said that the least distensible places were at the beginning and at a point behind the summit of the aortic arch. This point might be pressed on by aneurism of the arch and, therefore, constrictions in this

region should have history and physical signs most carefully studied. These narrowings, as shown by the casts, have a surgical significance. They determine the points at which ingested caustic solutions are most apt to be the cause of ulceration and stricture, they might cause an arrest of foreign bodies, where the narrowing in the esophagus is due partly to relations to other organs, changes in the latter might increase the degree of narrowing to the extent of producing a clinical stricture.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND

One Hundred and Ninth Annual Meeting, held in Baltimore, April 22-25, 1907

The President, DR. HIRAM WOODS, of Baltimore, in the Chair

Officers Elected

The following officers were elected for the ensuing year: President, Dr. Charles O'Donovan, of Baltimore, vice presidents, Drs. Roger Brooke, of Montgomery County, and H. A. Naylor and George W. Dobbin, of Baltimore, secretary, Dr. John Rührh, treasurer, Dr. William S. Gardner, members of council, Drs. Hiram Woods, St. Clair Spruill, Howard Bratton, Lewellys F. Barker, State Board of Medical Examiners, Drs. L. A. Griffith and J. A. Stevens, Committee on Library, Drs. J. Whitridge Williams, Harry Adler, H. Barton Jacobs, Mary Sherwood, T. B. Fletcher, Committee on Legislation, Drs. John D. Blake, Herbert Harlan, W. W. Goldsborough, delegate to American Medical Association, Dr. Harry Friedenwald, alternate, Dr. G. Milton Linthicum.

As the result of the organization of the society, there are now 900 members. The library, which formed the principal topic of discussion at the meeting, contains over 10,000 volumes, so that its present quarters are entirely inadequate. A canvass is being made to secure, from the profession and citizens of the state, a fund to purchase suitable grounds and to erect a \$100,000 building.

Domination of Therapeutics by Commercialism

The annual oration was delivered by DR. GEORGE H. SIMMONS, Chicago, his subject being "The Commercial Domination of Therapeutics and the Movement for Reform." The paper will appear in full in THE JOURNAL.

The Medical and Chirurgical Faculty, Its Debt to Itself and the Public

DR. HIRAM WOODS, Baltimore, in summing up his presidential address, said that the society's debt to itself is steady work in component branches to develop their own force. "Self reliance is the foundation of progress, but it is to be distinguished from self complacency. One's own limitations should be recognized and help sought if it will be useful. We should develop the spirit of cooperation. Misunderstandings sap strength. Criticism, based on inadequate information, is inconsistent with ordinary fairness. Knowledge can always be obtained by inquiry."

"Our teachers should promote medical organization by instilling into students proper conceptions of their position as members elect of an honorable profession, and should help young men to apply principles of medical honor to student life. Much worthless and unworthy material will thus be eliminated. By graduation time students should know about the State Faculty and how it can help them. The duty of improving the tone of our profession and eliminating quackery lies at the door of the individual. Legal machinery is adequate, enforcing spirit must come from us. We must develop work among our younger men and make them active factors in the Faculty's life. This should be done through establishing new lines of public usefulness and the study of medico social questions."

"To the public we owe something more than knowledge of disease. We should take the position of public educators in matters affecting public good and physical well being. We should secure better relations with the press by giving it, for deliverance to the public, something worth knowing. Legislators should not be left to find information on medical matters

where they can get it, but we should take it to them and use our influence as a united body. All this, at least in my opinion, is only the logical sequence of medical organization. It is antagonized by traditional interpretation of medical ethics, to a greater or less degree. But we are living under a new code which puts ethical responsibility on individual honor rather than on arbitrary rules. This must be the basis of medical organization, for if the factors are faulty the whole will be useless."

The Logical Basis of Neurasthenia.

DR. A. KERR BOND said that "all nerve response is dual, with every nerve impulse is associated its limiting impulse. When nerve force is called into activity, there is evoked like wise its control to restrain it within its proper bounds of area and intensity and duration. With the wakening of any nerve force there is a simultaneous wakening of a definite accompanying force designed to control it. With the neurasthenic we have to deal not only with the cells too fatigued or weak for active impulse, but possibly with cells too fatigued or weak for the twin impulse to restrain. In America we do things to excess in every line of work. In that respect we are a race of neurasthenics."

"Patent" and Proprietary Medicines

DR. LOUIS B. HENKEL, JR., of Annapolis, spoke of cocaine in nerves, in salves and plasters, of arsenic in skin disease remedies, of iodine in rheumatism remedies, of opium in soothing syrups, of nostrums containing nitroglycerin, of stomachic and digestion remedies containing alcohol, of headache remedies causing weak heart, of hair dyes and bleaches injuring the hair and producing baldness.

Indications for Operation in Chronic Suppurative Otitis Media

DR. H. O. REIK explained the pathology of this disease and referred to the various methods of treatment, according to the conditions encountered in different cases. The prognosis of chronic suppurative otitis media was stated to be good if proper methods of treatment were employed, and he expressed the belief that if due care was exercised in diagnosing the factors accountable for chronicity in each case and conscientious efforts made to remove or overcome them that only a small minority of even the most chronic otorrheas would require the so called radical operation. He believed that this operation should properly be held in reserve as a last resort for those cases which do not succumb to milder forms of treatment or simpler surgical measures. He offered the following rules for guidance when considering the treatment of persistent chronic suppurative otitis media: 1. Broadly speaking, practically every case of suppurative otitis media is assumed to be susceptible of cure by one means or another. 2. Every case of chronic suppurative otitis media, without symptoms of intracranial invasion, should be treated patiently and persistently for a reasonable length of time, but not indefinitely, by well directed efforts at cleanliness and antisepsis through the external auditory canal. When it becomes evident that these simple measures or minor operations can not cure the disease, tympano mastoid exenteration should be advised, unless in a given case there exists some special reason to justify delay and the risks of the disease. 3. The possible dangers of the operation are believed to be far less than those of the disease. 4. The patient should be told that not every case is curable, even by an operation (the percentage of cures in the obstinately chronic cases probably approximating 70 per cent), that the hearing power will probably not be improved and may be somewhat impaired, but that the serious nature of his disease warrants surgical intervention as a prophylactic measure.

Erysipelatous Cellulitis.

DR. HARRY FRIEDENWALD reported a case of erysipelatous cellulitis of the eyelids in a child, 2 years of age. Threatened gangrene is believed to have been averted and high fever (104°) was promptly reduced by the use of antistreptococcus serum.

The Present Status of Vaginal Cesarean Section.

DR. L. M. ALLEN drew the " That vaginal Cesarean section has a field of

operative obstetrics, but that its indications are limited to those cases where the cervix is not dilated by gentle means, and the pregnancy not advanced beyond the thirty-fourth week. That experience and a careful study of the cervix will demonstrate the fact that it is dilatable by gentler means much more frequently than is ordinarily believed, and if this method be persisted in more radical measures will not be so often necessary. That we should not allow the desire to perform this much talked of operation to overbalance our better judgment, and that certainly for the average man more conservative obstetrical operations will be attended by better results than the more radical ones.

Appendicitis

DR. RANDOLPH WINSLOW reported a case of appendicitis in which the symptoms were so mild that he left the result to Nature. Some days later, while the patient seemed to be convalescing satisfactorily, gangrene set in in the leg and extended up to the knee. The limb was amputated and the patient made a good recovery.

A joint meeting of the society with the Maryland State Conference of Charities and the Maryland State Federation of Women's Clubs was held on the afternoon of April 25. The principal address was made by Dr. Prince A. Morrow, of New York City, on "The Prophylaxis of Social Diseases." Others who addressed a crowded mixed audience on these affections were Dr. Lillian Welsh, Dr. Charles P. Emerson, Dr. Flora Pollack, Dr. Howard A. Kelly and Assistant Commonwealth Attorney Eugene O'Dunne. At the conclusion of this discussion, which created a marked interest, a motion was adopted to organize a Baltimore branch of the American Society of Sanitary and Moral Prophylaxis, and a committee was appointed to carry this motion into execution.

Many other interesting papers were read.

SOUTH CAROLINA MEDICAL ASSOCIATION

*Fifty-ninth Annual Meeting, held in Bennettsville,
April 16-18, 1907*

The President, DR. T. PRIOLEAU WHALEY, in the Chair.

Since the adoption, two years ago, of the plan of organization suggested by the American Medical Association, the South Carolina Medical Association has increased in membership from 300 to 735. It is estimated that about 1,100 physicians are in active practice in the state, and earnest efforts are being made, with every hope of success, to bring the majority of those now unaffiliated into the fold.

Officers Elected

The election of officers for the year resulted as follows: President, Dr. Legrand Guerry, Columbia, vice presidents, Drs. R. A. Marsh, Edgefield, J. A. Hayne, Greenville, Mary R. Baker, Columbia, secretary, Dr. Walter Cheyne, Sumter, treasurer, Dr. C. P. Aymar, Charleston.

The next meeting will be held in Anderson, April 15-18, 1908.

Sexual Ignorance Versus Sexual Knowledge

DR. WALTER CHEYNE, of Sumter, contended that the education of young girls and boys in the proper care of the sexual organs is the only hope for overcoming the disorders incident to certain diseases by preventing the spread of gonorrhea and syphilis. It need not be considered immodest for the mother or father to instruct the child. He recommends the insertion of chapters on sexual hygiene in school physiologies, but not to be studied in mixed classes, proper home instruction, father to son, mother to daughter, greater efforts of the physician for the dissemination of sexual knowledge and its importance among the laity. He also advocated the compulsory examination and legal quarantine of diseased prostitutes.

DISCUSSION

DR. WHEEL thought a marriage license law, requiring payment of the applicant for license, should be no license in South Carolina.

DR. ROBERT WILSON thought the registration and segregation of prostitutes might tend to increase immoral practices by holding out a guarantee of immunity from disease, of which there could be no certainty. He also called attention to the fact that the discussion of sexual matters excite certain natures, and advised extreme caution and tact among physicians and parents in carrying out Dr. Cheyne's idea.

The County Society

DR. J. W. JERVEY, of Greenville, urged on the members the importance of exercising their political influence in matters pertaining to the practice of medicine and the health of the state. He expressed the conviction that the recent defeat of certain candidates for governor and attorney general was due, in large measure, to their attitude in the general assembly toward matters of legislation suggested by the state association. Certain newspapers of the state misunderstood this reference to politics and warmly scored Dr. Jervy and the profession for political tendencies. Other papers took a broader view of the question and commended the views expressed. The publication of a card of explanation by Dr. Jervy has reversed the attitude of the unfavorable press, and the notoriety given the matter among laymen will undoubtedly strengthen the hands of the medical fraternity in their future efforts for favorable legislation.

Other Papers Read.

The following papers were also read:

MEDICAL ASSOCIATION OF GEORGIA

Fifty eighth Annual Session, held at Savannah, April 17-19, 1907

(Concluded from page 1545)

Methylene Blue in the Treatment of Cancer

DR. HENRY R. SLACK, La Grange, said that ten years ago he read a paper on this subject, which was published in THE JOURNAL, June 27, 1897. In this paper he reported 5 cases, and has since treated 20, but gave only 3, as they are fairly representative. He has selected these 3 cases not because they have given the most brilliant results, but because of their peculiar interest. Case 1 had been pronounced an inoperable carcinoma of the breast over four years ago had yielded for a time to Roentgen rays, but after several burns tolerance was established and the disease spread, causing much pain and destroying health. On administering and applying the methylene blue, the disease again yielded, and the patient is now enjoying fairly good health and is free from pain. Case 2 was an epithelioma of the left lower lid, which was benefited by Roentgen rays, but the patient did not get well until the methylene blue was used. Case 3 was one of carcinoma of the uterus following laceration of the cervix, which is being arrested by administration of methylene blue alone.

Of the 20 patients treated with Roentgen ray or combined with methylthionin hydrochlorid, 12 have been dismissed as

cured, and 5 have gone over three years without recurrence. The other seven, ranging from five to thirty months since dismissal, shows no evidence of return. There are 9 still under observation, 7 of whom are doing fairly well, as the disease is in abeyance. They suffer very little, and are able to attend to their usual duties. Of the 12 patients cured, 8 had epitheliomas, 3 carcinomas and 1 a sarcoma.

His experience with the methylthionin hydrochlorid teaches him to expect the following results: 1. Everything with which it comes in contact is stained a deep blue, the urine soon looks like blue ink, and the practitioner should always tell the patient to expect this. 2. There is surcease from pain. 3. The general health of the patient is improved and years are added to his life.

Cough and Its Treatment in Tuberculosis

DR. M. M. SALIBA, Savannah, said that in most cases of tuberculosis the cough is due to irritation of the large air tubes, notably the larynx or at the bifurcation of the trachea, and it is usually associated with more or less catarrh. This kind of irritable cough is best treated with inhalations, dry or moist. The moist inhalations consist of steam, impregnated or not with some balsamic or stimulating aromatic substances, or with some more sedative drug. The dry inhalations are more efficacious and are certainly more convenient. When an asthmatic tendency is associated with phthisis, opium or stramonium cigarettes will, perhaps, be found the best remedy for the night cough. When the cough depends on laryngeal disease, the remedies chosen will be determined to a great extent by the conditions of the larynx, and it may be necessary to apply some sedatives, i. e., cocaine and morphin, directly with a brush. A simple means of allaying the cough of laryngeal irritation is sipping iced water. When the cough is due to irritation or hypersensitiveness of the pharynx, combined with laryngeal irritability, a good plan is first to wash away the catarrhal secretion by a warm borax gargle, and then brush the mucous membrane of the pharynx and larynx with a sedative solution.

Fracture of Femur

DR. JABEZ JONES, Savannah, exhibited an apparatus for the treatment of fractured femur. In the operation of wiring a fractured femur he emphasized two points, the first of which is never make an incision until the limb has been rendered bloodless. Hemorrhage is very alarming when a tourniquet is not used. Second, never operate unless assured of as nearly perfect asepsis as surgery gives to day.

Aneurismorrhaphy

DR. CRAIG BARTOW, Savannah, in the past three years has operated on 4 cases, successfully performing two reconstructive endo aneurismorrhaphies, one obliterative and failing in an other.

Multiple Abscess of Pelvis

DR. E. C. DAVIS, Atlanta, said the proper handling of suppurating conditions is one of the most difficult of all surgical problems, and one which taxes the ingenuity and skill to the highest possible degree, when we add to this the liberation of numerous adhesions and devitalization of tissues to such an extent that sloughing ensues, there was materially added to the difficulties of the problem the dangers of the operative procedures. The case he reported accentuated these difficulties markedly. It illustrated several points which he sums up as follows: 1. Is there any correlation between chronic pelvic suppuration and glycosuria? 2. Nature may cast off a large piece of intestine and recovery ensues. 3. Nature endeavors to make an anastomosis, pointing out what the surgeon ought to do. 4. The utilization of suture material in place of mechanical devices to approximate the ends of intestine. Since this report was contemplated, the author has resected the large and small intestines, using the same suture, with perfectly satisfactory results and no leakage.

Suprapubic Prostatectomy

DR. E. R. CONSON, Savannah, summarized his paper as follows: The suprapubic route is preferable in the majority of cases. The operation is simpler, can be done more quickly,

cuts fewer tissues, with much less chance of injuring the rectum or prostatic urethra, and with it the sexual function. This route is even better when the patient's condition demands two stages for the operation. He believes the profession is gradually coming to view the suprapubic route as the better of the two in the majority of cases.

Surgical Anesthesia.

DR J M SIGMAN, Savannah, said that no patient should ever be allowed to leave the operating table before being given a stimulant if there is the slightest indication for it. There are more fatalities from neglecting a weak heart in the first two hours after an operation than ever occur while the patient is under anesthesia. A safe anesthetic is dangerous in incompetent hands. A dangerous anesthetic can be given safely by an experienced, competent man. The author thinks that more will depend in many cases on the work of the anesthetist as regards the ultimate recovery of the patient than on the surgeon. Nurses and undergraduates should not be entrusted with a general anesthetic. The anesthetist should be held accountable for the patient's condition while on the table, and to do this legally he must be a licensed physician. All surgeons know that a good anesthetist is almost indispensable, yet there is no class of work given so little encouragement, and few men are willing to follow this line until they become proficient with the first requirements of a good anesthetist.

Rupture of the Uterus

DR. A. P. HANIE, Hartwell, reported a case of rupture of the uterus in which the fetus escaped into the abdominal cavity. He operated, removed the fetus, and the patient recovered.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr M A Clark, Macon, vice presidents, Drs Ralph M Thompson, Savannah, and E E Murphy, Augusta, secretary treasurer, Dr Louis H Jones, Atlanta, delegates to American Medical Association, Drs George R. White, Savannah, and F H. Harris, Atlanta.

Fitzgerald was selected as the place for holding the next meeting.

Marriages

GEORGE STEURNAGEL, M.D., to Mrs Jean L Haskell, both of Chicago, April 27.

FRANCIS C DUCKWALL, M.D., to Miss Alice Brown, both of Scott, Ohio, April 24.

JAMES M NEALON, M.D., to Miss Margaret Roan, both of Plymouth, Pa., April 18.

EDWARD W BANKER, M.D., to Miss Lucile A Donaldson, both of Aurora, Ill., April 24.

ROBERT H. P. ELLIS, M.D., Baltimore, to Mrs Ida Van Bussum, at Belair, April 30.

ALICE LILIENTHAL, M.D., Brookline, Mass., and D Walther Hirshberg, of Boston, recently.

OLIVER J GRAY, M.D., Wilmington, Del., to Miss Viola Anderson, of Folston, Md., April 17.

ABEL J BAKER, M.D., Grand Rapids, Mich., to Miss Jeannette M Baer, of Portage, Mich., April 17.

GAYLORD CRAWFORD HALL, M.D. to Miss Gertrude Dorothy Laib, both of Louisville, Ky., April 25.

PHILIP KINGSWORTH GILMAN, M.D. Baltimore, to Mrs Ellen Cary Burbank, at Wilmington, Del., March 2.

THOMAS JOSEPH GILMORE, M.D. Williamsport, Pa., to Miss Mary Lyle Sloan, of Orangeville, Pa., April 20.

WILLIAM DICK CAMPBELL, M.D., Hagerstown, Md. to Miss Marie Louise Parsons, at Piedmont, Va., April 24.

PAUL R OESER, M.D., Lawrence, Mass., to Miss Grace Davidson of New London, Conn., in New York City, April 30.

DAVID CUSHMAN TWICHELL, M.D., Saranac Lake N Y. to Miss Ella Goodridge Cooke, at Green Spring Valley, Md. Mar 2.

EDWIN E STRAW, M.D., Marshfield, Ore., to Miss Sarah C Lakeman, of Mountain View, at Santa Rosa, Cal., April 19.

Deaths

George W Smith, M.D. University of Pennsylvania Department of Medicine, Philadelphia, 1863, a member of the Medical Society of the State of Pennsylvania and for many years president of the Blair County Medical Society, assistant surgeon of the Fifty fourth Pennsylvania Volunteer Infantry during the Civil War, for more than twenty years United States pension examining surgeon, for many years a member and for ten years president of the Hollidaysburg Board of Health, physician to the Blair County almshouse and Blair County jail, died at his home in Hollidaysburg, April 22, from cerebral hemorrhage, after an invalidism of about five years, aged 72.

Charles Griffith Worthington MacGill, M.D. University of Maryland School of Medicine, Baltimore, 1856, a member of the American Medical Association, surgeon of the Second Virginia Infantry, C S A., for more than thirty years a member of the board of visitors of the Maryland Hospital for the Insane Catonsville, once a member of the board of school commissioners of Baltimore County, vice president of the Medical and Surgical Society of Maryland, and president of the First National Bank of Catonsville, died at his home in that place, April 28, from heart disease, aged 73.

Wilson Cary Nicholas Randolph, M.D. University of Virginia Department of Medicine, Charlottesville, 1855, a grandson of Governor Randolph of Virginia and a great grandson of Thomas Jefferson, surgeon in the Confederate service during the Civil War for 17 years a member of the board of visitors of the University of Virginia, and for eight years rector of the university, died at his home in Charlottesville, April 26, from pleurisy, after an illness of three days, aged 73.

Flavius J Taylor, M.D. Kentucky School of Medicine Louisville, 1865 a member of the Kentucky State Medical Association and secretary of the Barron County Medical Society, formerly a member of the city council, editor of the Glasgow Republican secretary of the board of pension examiners, assistant surgeon in the United States Army during the Civil War, died at his home in Glasgow, April 21, from cerebral hemorrhage, after a long illness, aged 70.

William G McFadden, M.D. Jefferson Medical College, Philadelphia, 1870, surgeon of the Seventy ninth Indiana Volunteer Infantry, and later brigade surgeon of the First Brigade, Third Division Twenty first Army Corps, captured at Chickamauga and imprisoned in Libby prison, Richmond for three months, after the Civil War a practitioner of Shelbyville, Ind., died in Daytona, Fla., from heart disease April 20, aged 73.

George Nichols, M.D. Vermont Medical College, Woodstock 1851 surgeon of the Thirtieth Vermont Volunteer Infantry in the Civil War, state librarian of Vermont from 1848 to 1853, secretary of state of Vermont from 1865 for several years president of the Northfield National Bank, died April 27, at his home in Northfield, Vt., from nephritis, aged 79.

Edwin M Shaw M.D. Medical College of Ohio, Medical Department of the University of Cincinnati, 1885 a member of the State Medical Association of Texas and the Victoria County Medical Society, died at his home in Victoria January 1 from angina pectoris and hemorrhage of the lungs, after an illness of three days, aged 49.

Thomas Withers Dresser, M.D. New York University Medical School, New York City 1864, surgeon in the Confederate service during the Civil War and for 40 years a practitioner of Springfield Ill. died at the home of his daughter in East St Louis Ill. April 27, from pneumonia, after an illness of nine days, aged 70.

Andrew Thomas Dunn M.D. University of Buffalo (N Y) Medical Department, 1863 Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons, Kingston Ont. 1864, died at his home in North Augusta Ont. January 16, after an illness of four or five years, at an advanced age.

F W Bernhard von Buest, M.D. University of Leipzig Germany during the Civil War brigade surgeon on the staff of Gen Burnside and Gen Gordon some time member of the New Albany (Ind.) board of health, died at his home in New Albany Ind., from exhaustion due to chronic diarrhea, April 3, aged 76.

Winthrop Butler, M.D. Medical School of Harvard University Boston, 1876 assistant surgeon in the United States Navy during the Civil War a member of the Massachusetts Medical Society and the Bristol South District Medical Association, died at his home in Vineyard Haven, Mass. April 20.

John N Groves, M.D. Rush Medical College, Chicago, 1866, a member of the Illinois State and Effingham County medical societies, during the Civil War surgeon of the Ninety eighth Illinois Mounted Infantry and of the Fourth Michigan Cavalry, died at his home in Effingham, April 26, after an illness of five days

John P Wilson, M.D. University Medical College of Kansas City, Mo., 1902, of Liberty, Mo., a member of the Missouri State Medical Association and Clay County Medical Society, coroner of Clay County, was crushed under an overturned wagon, near Randolph, and died April 25, aged 37

Amos T Williams, M.D. University of Pennsylvania, Department of Medicine, Philadelphia, 1900, of Ridgway, Pa., a member of the Medical Society of the State of Pennsylvania and of the Elk County Medical Society, died at Southern Pines, N. J., February 18, from heart disease, aged 34

Irene Dupont Young, M.D. Pennsylvania Medical College, Philadelphia, 1848, a member of the Medical Society of New Jersey and Burlington County Medical Society, consulting surgeon at Mercer Hospital, Trenton, N. J., died at his home in Bordentown, N. J., April 26, aged 82

John Kautz, M.D. Hospital College of Medicine, Louisville, Ky., 1874, a veteran of the Civil War and for many years a practitioner of Dora, Ind., died at the home of his son in Irvington Indianapolis, April 24, from bronchitis, after an illness of a few weeks, aged 72

Charles Wayne McCoy, M.D. Jefferson Medical College, Philadelphia, 1889, of South Point, Ohio, a member of the Ohio State Medical Association and Lawrence County Medical Society, is reported to have been shot and killed by John Davis, May 2, aged 40

David Yandell Walsh, M.D. University of Louisville (Ky.) Medical Department, 1897, a member of the Kentucky State and Jefferson County medical societies, died at his home in Louisville, April 28, from pneumonia, after an illness of two weeks, aged 30

Melvin B Hubbs, M.D. College of Physicians and Surgeons, Baltimore, 1883, formerly president of the Steuben County (N. Y.) Medical Society and president of the village of Addison, died at his home in that place, April 24, aged 55

andover L Chester, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1880, for many years a practitioner of urthage, Mo., died at his home in that city, April 24, from diabetes, after an illness of three months, aged 64

William Huntington Leonard, M.D. Medical Institution of Yale College, New Haven, Conn., 1853, who had practiced medicine in Minneapolis, Minn., for 52 years, died at his home, April 29, after an illness of almost a year, aged 85

John Lafferty, M.D. Homeopathic Hospital College, Cleveland, 1876, formerly a member of the board of deputy state supervisors of elections, died at his home in Columbus Grove, Ohio, April 11, after an illness of two months, aged 60

Herbert K Stiles, M.D. Medical School of Harvard University, Boston, 1895, formerly house surgeon at Carney Hospital, Boston, of Somerville, Mass., died April 27, at Everett, Mass., from pneumonia, after a short illness, aged 38

Louis J Schifferstein, M.D. St. Louis (Mo.) Medical College, 1873, a member of the Illinois State and Effingham County medical societies, a practitioner of Effingham for 25 years, died at his home in that city, April 26, aged 57

Guy C Holcomb, M.D. Jefferson Medical College, Philadelphia, 1887, a member of the Bradford County Medical Society and formerly coroner of Bradford County, died at his home in Ulster, Pa., from tuberculosis April 25, aged 41

Thomas J Myers, M.D. Philadelphia College of Medicine and Surgery, 1850, a member of the De Soto (Fla.) County Medical Society, formerly surgeon of the Plant System, died at his home in Bowling Green, Fla., April 21, aged 80

A. G. Henderson, M.D. Jefferson Medical College, Philadelphia 1861, a member of the Medical Society of the State of North Carolina and Rowan County Medical Society, died at his home in Woodleaf, N. C., March 27, aged 74

Frank P Webster, M.D. College of Physicians and Surgeons, Baltimore, 1878, Hahnemann Medical College and Hospital, Philadelphia, 1879, died suddenly from heart disease, April 26, at his home in Norfolk, Va., aged 54

Ed L Burdick, M.D. College of Physicians and Surgeons, St. Joseph Mo., 1871, a veteran of the Civil War, later a member of the state legislature of Arizona and county treasurer, died at his home in Azusa Cal April 10

John James Blacklock, M.D. McGill University Medical Faculty, Montreal, 1851, for 40 years coroner of Stormont, Dun

das and Glencarry counties, Ont., died at his home in Morrisburg, Ont., recently, aged 83

Joseph C Hall, M.D. Medical College of Ohio, Medical Department of the University of Cincinnati, 1873, died at his home in Decatur, Ill., from uremia, April 24, after an illness of several weeks, aged 67

Isaac T Lechtman, M.D. University of Kowno, Russia, 1864, some time surgeon in the Russian army, and president of the Missouri Medical Society in 1893, died at his home in St. Joseph, Mo., April 11

Claud A. Thixton, M.D. Hospital College of Medicine, Louisville, 1894, of Louisville, died at his family home, Fairmount, near Louisville, April 27, from typhoid fever, after an illness of eight weeks, aged 37

Gustave Schoenberg, M.D. University of Berlin, Germany, 1848, surgeon in the Japanese service from 1874 to 1877, died at his home in Philadelphia, April 19, after an illness of seven years, aged 81

Alfred A. Moors, M.D. Memphis Medical College (Medical Department of Cumberland University, Memphis, Tenn.) 1854, formerly of West Winfield, N. Y., died in Buffalo, N. Y., March 24, aged 75

Charles D Mattison, M.D. College of Physicians and Surgeons, Baltimore, Md., 1899, died at his home in Minnetonka, N. Y., April 22, from the effects of an overdose of chloral, aged 35

Robert Purdon McCready, M.D. Jefferson Medical College, Philadelphia, 1905, physician to the Maryd (Pa.) Coal Company, died at Tamaqua, Pa., April 28, from peritonitis, aged 29

Elijah J Galbraith, M.D. Medical College of Ohio, Medical Department of the University of Cincinnati, 1870, died at his home in Chillicothe, Ohio, April 23, after a long illness, aged 68

William Gadson Allen, M.D. Maryland Medical College, Baltimore, 1905, died at his home in Surrency, Ga., March 21, from typhoid fever, after an illness of 26 days, aged 27

Felix Fernere, M.D. American College of Medicine, Pennsylvania, 1898, died recently at his home in St. Joseph, Mo., from senile debility, and was buried April 29, aged 86

William H Morgan, M.D. Rush Medical College, Chicago, 1874, died at his home in Middletown, Ind., April 18, from tuberculosis, after an illness of a year, aged 67

Benjamin Tomlin, M.D. Cincinnati College of Medicine and Surgery, 1865, died at his home in St. Louis, April 26, from pneumonia, after an illness of ten days, aged 72

Lorenzo D Wiggins, M.D. Geneva (N. Y.) Medical College, 1865, a veteran of the Civil War, died at his home in Wayland, Iowa, April 9, from pneumonia, aged 86

J Leroy Blakeman, M.D. New York Homeopathic Medical College and Hospital, New York City, 1899, died at his home in New York City, March 20, aged 34

George Irvin, M.D. Jefferson Medical College, Philadelphia, 1855, died at his home in Aledo, Ill., April 22, from angina pectoris, after a short illness, aged 81

John Edgar March, M.D. Bellevue Hospital Medical College, New York City, 1879, died at his home in Partridge Island, St. John, N. B., April 3, aged 50

Andrew Harkness, M.D. McGill University Medical Faculty, Montreal, 1869, died from pneumonia at his home in Lancaster, Ont., February 8, aged 61

George Leibrock, M.D. Homeopathic Medical College of Missouri, St. Louis, 1878, died at his home in Mascoutah, Ill., January 24, aged 78

Charles M Kellogg, M.D. University of Buffalo (N. Y.) Medical Department, 1884, died at his home in Rochester, N. Y., March 29, aged 61

Eton B Crowell, M.D. Eclectic Medical Institute, Cincinnati, 1895, died at his home in Minneapolis, Minn., April 15, from nephritis, aged 47

Sarah M. Leahy, M.D. Northwestern University Woman's Medical School, Chicago, 1895, died at her home in Anaconda, Mont., in March

Andrew D Ingleright, M.D. American Health University, Chicago, 1895, died at his home in North Liberty, Ind., April 10, aged 65

Adam A. Simmons, M.D. Eclectic Medical Institute, Cincinnati, 1865, died at his home in Girard, Ill., April 22, aged about 80

Esrom Aram Duclos, M.D. McGill University Medical Faculty, Montreal, 1874, died at his home in Fall River, Mass., April 10

Medical Education and State Boards of Registration

COMING EXAMINATIONS

MISSISSIPPI State Board of Health State Capitol Jackson May 14 Secretary Dr J F Hunter, Jackson.
MASSACHUSETTS Board of Registration in Medicine Room 15 State House Boston, May 14-16 Secretary Dr E B Harvey Boston
FLORIDA State Board of Medical Examiners (Regular) Jacksonville May 15-16 Secretary Dr J D Fernandez, Jacksonville
NEW YORK State Boards of Medical Examiners, Albany May 21
24 Chief of Examining Division Charles F Wheelock Albany
NEBRASKA State Board of Health State House, Lincoln, May 28
29 Secretary, Dr Geo H Brash Beatrice
INDIANA Board of Medical Registration and Examination, Room 120 State House Indianapolis, May 28-31 Secretary Dr W T Gott, Indianapolis

Missouri State Board Questions—Dr J A B Adcock, secretary of the Missouri State Board of Health, sends us the following list of questions asked at the examinations held in St Louis and Kansas City, April 16 18, 1907

BACTERIOLOGY

1 What is meant by 'alexins'? 2 Describe in detail Widal's test 3 Explain serum therapy and give two illustrations 4 Describe a method for distinguishing the typhoid bacillus in a post typhoid abscess 5 Give in detail a method of staining tubercle bacilli (a) in fluids (b) in sections

JURISPRUDENCE

1 What is superfetation? 2 What is a hermaphrodite? 3 What is sodomy? 4 What are ptomaines? 5 In what food is tyrotoxin found?

HYGIENE

1 Mention three diseases in which you would institute quarantine Give period of incubation length of quarantine and prophylaxis in each 2 What do you understand by (a) antiseptics (b) disinfectants, (c) deodorants. Name three of each class and method of using them 3 Mention three chemical agents frequently found in milk used as preservatives Give test for two of them 4 What do you understand by ventilation? How much cubic space should be given a school room containing 100 children to insure fresh air? 5 What do you understand by (a) toxins (b) anti-toxins (c), predisposition (d) immunity

ANATOMY

1 Name the cranial nerves in their order and with reference to their function 2 Name the salivary glands. Give exact location and name of ducts through which they discharge 3 Give origin insertion and function of the following muscles (a) Trapezius (b) sternomastoid (c) sartorius (d) pectoralis major 4 Describe the shoulder joint. 5 What is (a) Lymph (b) cellular tissue (c) adipose tissue (d) muscular tissue. 6 Describe femoral artery Give its branches 7 Give landmarks for locating the mastoid cells. 8 What is the (a) epiblast (b) hypoblast, (c) mesoblast, and what anatomic structures are formed by each? 9 Give regions of the abdomen and their contents 10 Mention all abdominal viscera not completely invested by peritoneum

PATHOLOGY

1 Give the pathologic changes in chlorosis 2 Give the pathologic changes in cirrhosis of the liver 3 Discuss the process in local infection. 4 Discuss the formation of gallstones 5 Describe the gross appearance of the kidney in chronic interstitial nephritis

CHEMISTRY

1 What is the chemical composition of muscular tissue? 2 Give toxicology of opium and treatment for same 3 Give test for arsenic (b) for sulphuric acid, (c) for nitric acid. 4 What are some of the chemical characteristics of the chlorides of mercury? 5 Give chemical changes occurring in food during process of intestinal digestion

SURGERY

1 Describe in detail the examination and treatment of a scalp wound inflicted by a blow on the head 2 Give the symptoms and treatment of a penetrating wound of the trachea 3 Give the causes symptoms and treatment of acute infective lymphangitis 4 What are the causes and symptoms of fracture of the patella and what is the object to be accomplished in the treatment? 5 Differentiate purulent and sanguineous effusion into the knee-joint and describe the treatment of each condition 6 Enumerate the symptoms of tetanus and instituted after the disease has appeared 7 By what symptoms would you recognize and how would you treat a penetrating wound of the urinary bladder? 8 Describe the steps to be taken in the first dressing of an open oblique fracture of the tibia. 9 Describe the amputation at the knee giving the incisions the structures divided and the dressing of the stump 10 Give the symptoms and a method of reducing a sub-glenoid dislocation of the humerus.

THERAPEUTICS

1 to 10 give indications for use of aconite belladonna gelsemium eucalypta digitalis nuxvomica opium quinin, mercury veratrum viride

GYNCOLOGY

1 Describe ovaritis Describe ovariagia. Give treatment of each. 2 Describe endometritis Give pathology etiology and treat 3 Define vaginitis, giving pathology etiology and treatment 4 Define pruritus vulva, giving pathology etiology and treatment 5 Define prolapsus uteri, giving pathology etiology and treatment

OBSTETRICS

1 When should chloroform be used in a case of labor? Give its effect on mother and child When is it contraindicated? 2 Distinguish between adherent and retained placenta. Give manner of treating each 3 Give cause and treatment of mammary abscess in the puerperal state 4 Give after treatment of incomplete abortion Give symptoms and treatment of threatened abortion 5 Give method of caring for the umbilical cord. Discuss hemorrhage of the cord. Give treatment of each 6 Distinguish a primipara from a multipara 7 Give description of the placenta and umbilical cord giving their origin and function 8 Distinguish false from true labor pains What is morning sickness? Give treatment for the same 9 Give manner in which new born should be washed and dressed first time. 10 Give indications for induction of premature labor with best time for same and prognosis

PHYSIOLOGY

1 Describe cerebellum and give its function 2 Name digestive ferments and give function of each 3 Describe the heart cycle 4 Give brief description of special sense of hearing 5 (a) Describe mammary gland and process of milk secretion (b) Also causes that lead to variation in quantity and quality of milk 6 Name ductless glands and give supposed office of each 7 What do you understand by internal respiration? 8 (a) On what does temperature of human body depend? (b) Why in a healthy individual does it remain practically constant? Given an exposed artery and vein in the living subject, how would you distinguish them without reference to anatomic landmarks? 10 Describe the pneumogastric nerve and give its functions

PRACTICE

1 What is dropsy? Give the name or terms by which the various dropsies are known and their location. 2 Give symptoms and treatment of diabetes mellitus 3 Give the etiology symptoms and treatment of pericarditis 4 Give the etiology symptoms and treatment of cerebrospinal meningitis 5 Give chief diagnostic symptoms of cancer of stomach 6 Describe (a) An irregular pulse (b) intermittent pulse (c) dicrotic pulse 7 What is meant by incubation period? 8 Discuss palpitation of the heart 9 How would you differentiate a functional derangement from an organic lesion? 10 Give etiology and symptoms of angina pectoris

Supreme Court Sustains Medical Practice Act—The United States Supreme Court has entered a decision in the case of the Washington State Medical Examining Board vs O V Lawson of Seattle, confirming the action of the Washington Supreme Court in sustaining the lower court in which Lawson was convicted of practicing medicine illegally and sentenced to three months in the county jail About two years ago the physicians of Seattle determined to put a stop to the illegal practice of medicine, as carried on in the state. A fund of \$2,000 was raised to prosecute illegal practitioners As a result, a little over a year ago, O V Lawson was sentenced to pay a minimum fine and to spend three months in the county jail At the time of his conviction he was conducting what he called the "State Medical Institute," and was doing an advertising business He was also proprietor of a concern known as the "Victor Medical Company" After being convicted in the lower court, he appealed to the Superior Court, thence to the Supreme Court of the state and finally to the United States Supreme Court The points made by him in his brief before the United States Supreme Court were that he was deprived of his liberty without due process of law, that he was deprived equally of the protection of the law contrary to the fourteenth amendment, and that the medical practice act of the State of Washington is unreasonable uncertain, indefinite, and therefore void The decision of the Supreme Court is of importance, not only in this case, but in several others of a similar nature which are pending, awaiting the decision on the Lawson case

Higher Requirements for Washington University and Sioux City College of Medicine—Dr Robert Luedeking, dean of the Medical Department of Washington University, St Louis, writes to us that at a recent meeting of the faculty it was decided to require besides a four year high school education, a year devoted to physics, chemistry, biology and one language as an additional entrance prerequisite after Jan 1, 1910 —Dr F E Franchere, of the Sioux City College of Medicine, Sioux City, Iowa, writes that a similar requirement has been adopted by that school There are now 45 schools which, after Jan 1 1910 will require one or more years of preliminary work in a college of liberal arts

Wyoming March Report.—Dr S B Miller secretary of the Wyoming State Board of Medical Examiners reports the written examination held at Laramie March 13 14 1907 The number of subjects examined in was 10, total number of questions asked 100 percentage required to pass 75 The total number of candidates examined was 4 all of whom passed. The following colleges were represented

Book Notices

LECTURES ON DISEASES OF THE LUNGS By J. A. Lindsay, M.D., F.R.C.P. Second Edition. Enlarged and Rewritten. Cloth. Pp 609. Price, \$4.00 net. New York: William Wood & Company.

Lindsay presents a clear and concise summary of the various diseases of the lungs from the point of view of their physical signs and diagnosis, with notes on treatment. Unlike many of the texts on physical diagnosis, it is neither too brief nor are the facts obscured by a multitude of words. Each chapter is preceded by a summary of its contents, thus giving at a glance an outline of the subject following. The earlier chapters consider the signs encountered in diseases of the lungs and pleura in general, explaining their occurrence as far as possible by reference to the physical conditions of the tissues. The author treats the subject of adventitious sounds simply and avoids the introduction of any new terminology. The chapters on pleurisy, empyema and pneumothorax will prove of particular interest and value to the student. The second portion of the book deals with the more important diseases in which the local process involves chiefly the lungs, including pneumonia and pulmonary tuberculosis. The discussion of pneumonia is not on a par with the standard of excellence set by the remainder of the book, and is evidently based on personal observations of a limited series of cases. The disease is considered almost exclusively from the point of view of the local trouble in the lung, with its accompanying toxemia, and space is unprofitably taken in the attempt to account for meta-pneumonic conditions which are easily explained if we recognize that in pneumonia we are dealing with a bacteriemia demonstrable by our modern blood culture methods.

The therapeutic treatment is taken up from a rational point of view, recognizing that no single drug is a panacea, and that the efforts of the physician must be directed toward combating the toxemia and supporting the heart. In this connection it is rather surprising that the author should declare emphatically against the practice of bleeding even in selected cases. Here again it would seem that the limited series of cases may explain the author's uncompromising stand against the "Bloody Moloch." The rather brief discussion of bronchitis, emphysema, bronchiectasis and asthma is followed by several admirable chapters on pulmonary tuberculosis. The section dealing with treatment and prognosis of pulmonary tuberculosis is decidedly hopeful in tone, in keeping with our more recent views that many of the early cases and not a few of those with more advanced lesions not only may improve, but may terminate in cure. A brief review is given of the newer work on the opsonic index in tuberculosis and the therapeutic use of minimal injections of tuberculin.

The book closes with chapters on the rarer forms of disease in the lungs and the special features of pulmonary disease in children. As a whole the book is clear in style, interesting and the arrangement of the subject matter good. It is well worth reading and study by student and practitioner alike.

ANATOMIC TERMINOLOGY with Special Reference to the Basle Anatomic Nomenclature. By Lewellys F. Barker, M.D., Professor of Medicine, Johns Hopkins University, Baltimore. With Vocabulary in Latin and English and Illustrations. Cloth. Pp 103. Price \$1.00 net. Philadelphia: P. Blakiston's Son & Co. 1907.

The BNA system of anatomic nomenclature has already been adopted in several anatomic laboratories and is used by some of the recent atlases and text books and has attained such importance that a work explaining it, such as the one before us, is very timely. The title in common use—BNA (Basle Anatomic Nomenclature)—is doubtless strange to many, but is as simple as the principles of the system which it denotes. The Basle Anatomic Nomenclature is an attempt to simplify terminology by adopting for each part only one Latin name as short and as simple as possible. The terms are to be merely memory signs and related terms as far as possible are to be similar. Adjectives in general are arranged as opposites—e.g., dexter and sinister, major and minor, etc. After giving some account of the way in which the system was formed, the book answers some of the objections to the plan and makes some suggestion to promote its adoption. Then follows a list of the terms in Latin with English equivalents.

It is to be remembered, however, that only the Latin terms are authoritative and the English terms are subject to variation as use may dictate. The systematic terms are not so different from those formerly in vogue as might be supposed, since they are mostly a selection from the terms formerly used. Personal names have been retained in some cases in brackets following the regular name. Thus we have *ligamentum inguinale* (Poupart). In time it will be known whether it is to be called ultimately the inguinal ligament or after Poupart's name. The book is of special interest to teachers and students of anatomy and to physicians who wish to understand the advanced system of nomenclature.

TREATMENT OF DISEASES OF THE DIGESTIVE SYSTEM. By R. Saundby, M.D., M.Sc., LL.D., F.R.C.P., Professor of Medicine in the University of Birmingham etc. Cloth. Pp 133. Price, \$2.75. Philadelphia: J. R. Lippincott Company, 1906.

In this small volume an attempt is made to give the diagnosis and treatment of diseases of the stomach and intestine. Although the author must be given credit for including in a small space the essentials of his subject, the limitations of space have entailed omissions which tend to impair the value of the work and in some instances lay it open to serious misinterpretation by the inexperienced reader. To mention two examples, we find the titration of the gastric juice directed to be carried out on 5 c.c. instead of 10 c.c. as is customary. The statement is then made that the quantities of acid are usually expressed by the number of cubic centimeters of sodium hydroxide solution needed to saturate the gastric contents. The reader is not informed whether the amount to be saturated is 5 c.c., as he would naturally infer from the previous directions, or 100 c.c., as is customary. In describing the test for blood in feces both guaiac and aloin are mentioned and the color produced if blood is present is said to be red, with no mention of the blue obtained when guaiac is used. No clinical applications of this test are given and the fallacy arising from the presence of meat in the diet is not mentioned.

The clinical observations and therapeutic advice are good. The author finds little reason to recommend the application of electricity in gastrointestinal diseases. Acids are useful, he states, but the explanation of their value is not in their digestive power, but in their tonic action. The digestive ferments receive little credit, the author calling attention to the fact that even malt preparations are seldom required because the diastase of the saliva is nearly always sufficient.

HISTOLOGIC OBSERVATIONS ON SLEEPING SICKNESS AND OTHER TRYPANOSOME INFECTIONS. By F. W. Mott, M.D., F.R.S. (From the Pathologic Laboratory of the London County Asylums). Cloth. Pp 50. Price \$1.50 net. New York: William Wood & Co. 1907.

It is now admitted that sleeping sickness is caused by the presence of the *Trypanosoma gambiense* in the lymphatic glands and cerebrospinal fluid. The disease is characterized by chronic polyadenitis, which is subsequently followed by a chronic inflammatory change in the lymphatics of the brain and spinal cord characterized by proliferation and overgrowth of the neuroglia cells, especially those which are related to the subarachnoid space and perivascular lymph spaces, with accumulation and probably proliferation of lymphocytes in the mesh work. The histologic changes produced are described in this volume.

The material used was from twenty-four natives and two Europeans with sleeping sickness and from the tissues of various animals infected with trypanosomes. The book is illustrated by a number of colored plates, showing the histologic changes, and must be regarded as an important contribution to the literature of tropical medicine.

HINTS ON THE MANAGEMENT OF THE COMMONER INFECTIONS. By R. W. Marsden, M.D., M.R.C.P., D.P.H., Honorary Physician to the Ancoats Hospital, Manchester. Cloth. Pp 128. Price \$1.50. New York: E. B. Treat & Co. 1907.

This work gives a brief résumé of the principles of treatment to be observed in the management of the commoner diseases due to the action of micro-organisms, either directly or indirectly. Under "General Measures," the author discusses the indications and contraindications for the application of cold baths in fevers, the importance of rest, ventilation and temperature of the sick room, principles of feeding, limitations of treatment by drugs, including the abuse of purgatives.

Under "Specific Infections" are considered invasion of the body by septic micro-organisms and the various contagious and infectious diseases. There are two appendices, one deals with isolation and the other with disinfection.

CATHOLIC CHURCHMEN IN SCIENCE. Sketches of the Lives of Ecclesiastics Who Were Among the Great Founders in Science. By James J. Walsh, M.D., Ph.D., LL.D. Professor of Medical History, Fordham University Medical School, Cloth. Pp. 221. Price, \$1.00 net. Philadelphia: The Dolphin Press, 1908.

Dr. Walsh has gathered in this neat little volume some biographical essays which he contributed to various Catholic papers. Among the scientists to whom chapters are devoted are several who were either physicians or noteworthy contributors to medicine. Copernicus, the great astronomer, Basil Valentine, founder of pharmacologic chemistry, Linares, founder of the Royal College of Physicians of London, Steno, for whom Steno's duct is named, and who was a famous geologist, Kircher, who pointed out contagion and presaged the discovery of bacteria, Haüy, the crystallographer, and Mendel, whose name is linked with our knowledge of heredity. Sufficient is given of the life of each individual to give the reader a general knowledge of the man and his work, omitting the unimportant details.

URINARY ANALYSIS AND DIAGNOSIS. By Microscopical and Chemical Examination. By L. Heltzmann, M.D. Second Revised and Enlarged Edition. 131 Illustrations. Cloth. Pp. 310. Price, \$2.50 net. New York: William Wood & Company.

In this edition great stress has been laid on microscopic examination of urine and especially on microscopic diagnosis, but the chemical examination has not been slighted. The tests given are those which may be made by the practitioner rather than those which require an extensive equipment such as can be found only in the large laboratories. The illustrations are not of the routine character found as a rule in text books of this kind, but have been drawn by the author from his own specimens.

PRACTICAL DIETETICS. With Reference to Diet in Disease. By Alida Frances Patee, Late Instructor in Dietetics, Bellevue Training School for Nurses, Bellevue Hospital, New York City. Fourth Edition. Cloth. Pp. 312. Price, \$1.00 net. New York: A. F. Patee.

Nurses and others who prepare food for the sick will appreciate this practical handbook. The recipes are simple and easily understood.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and methods of treatment for the diseases seen especially in every day practice. Contributions will be welcomed from our readers.]

THE METRIC SYSTEM AND HOW TO USE IT

W. A. Jolley, M.D.

BOULDER, COLO.

The revision of the United States Pharmacopeia, with its numerous changes, the work of the American Medical Association in educating the physicians by its investigations of the proprietary preparations, and the fight against patent medicines, have created an opportune time for physicians to get out of a rut and to take a step forward in therapeutics, the knowledge of which has been badly hampered by ignorance of pharmacy. A glance at the prescription file will show that a deplorable condition exists.

NEED OF A UNIFORM STANDARD

The first step will be a study of the methods of measurements employed. The standards are governed by custom and the physical characteristics of the substances to be handled. Custom has caused many arbitrary standards to suit specific needs, and, as a result, the same term may have a variety of values. For example, an ounce may mean 437.5 grains in the avoirdupois system of weights, or 480 grains in the apothecaries' weights. The term "drop" is even more uncertain, and yet it is used for fancied precision in handling toxic liquids like the tincture of aconite. The size of a drop is dependent (1) On the liquid to be selected, a drop of water is almost a

minim, but it takes four drops of chloroform to make a minim, (2) on temperature, which affects the size of drops, as one can see in handling hot and cold liquids, like syrups and oils, (3) on the size and shape of the orifice, which has a great influence on the size of the drop.

A drop of water is supposed to be a minim, and to weigh 1 grain. The actual weight is 0.9508 of a grain. The weight of an ounce (480 minims) of water then will be $480 \times 0.95 = 456.4$ grains. The quantity "grain" is an arbitrary standard obtained by stating that a cubic inch of water weighs 255.33 grains.

HOW THE METRIC SYSTEM WAS ACQUIRED

Such standards are so complex, cumbersome and inaccurate that scientific advancement required a system which would be suited to universal use and the accuracy which modern science demands. This system is called the metric system, and has been universally adopted by the scientific investigators who have accomplished so much work during the past twenty-five years. These men are on unknown ground, and unhampered by tradition they have been able to use this new system in their work. Advance along the line of scientific medicine has been retarded by the slipshod manner in which drugs have been prescribed.

All progressive physicians keep abreast with the latest theories and principles of diagnosis, yet these men will not exercise the same care in dispensing the toxic agents, which we call medicines, even when they know that life often depends on the accuracy of the dosage. Naturally some difficulty must be expected in changing methods which have been used for many years but we have been compelled to adopt new theories. We can change to the metric system without danger or friction, but it must be a genuine conversion. We must drop the old and take up the new without any modifications. Do not transpose doses from the one system to the other, but use the metric alone and insist that the druggists do the same. The metric weights and measures are as easily manipulated as the apothecaries', the difficulty is in computing the proper dosage. The same method should be applied in studying this new system as in acquiring a foreign language. We learn the name of a certain object in the new tongue, use it repeatedly, and in a short time we can associate the two without mental effort. In the metric system we should ascertain the value of a gram or cubic centimeter, then work with it until we are familiar with it. This will be our basis for all computations.

In dispensing many physicians use the familiar old standard of household measurement—a teaspoon. A moment's work with a graduate will show that with this standard we have long erred, for the contents are far above the dram, which we have always used as its equivalent. This error has been introduced into the metric system, for most tables give the equivalent of a teaspoonful as four (4) cubic centimeters. Actual tests will show that the usual teaspoon will hold five (5) cubic centimeters. The larger quantities used in writing prescriptions are multiples of 5, e. g.—50, 100, 250, 500, 1000.

(This subject will be continued.)

Diarrhea

Diarrhea is a term loosely though correctly applied to all forms of intestinal disturbance accompanied by the passage of liquid feces. The treatment of each form depends on its cause, diarrhea is not a disease but a symptom.

Treatment of the catarrhal form consists primarily in regulation of the diet, which should be made up chiefly of milk, boiled or predigested or of milk whey. Castor oil or some other mild purge such as sulphate of magnesium should be administered to sweep out fermenting food or mucus. Enough ladanum should be given with the oil to prevent griping. Here in "Practical Therapeutics" states that it is well to add bicarbonate of soda grains xx to xxx (12 to 20) to the dose both to aid the action of the oil and to render the bowel alkaline (normal) in reaction instead of acid as caused by the fermentation. A mustard plaster or other counterirritant should be applied to the abdomen. Often the milder forms of mucous diarrhea that is but sometimes it is necessary to f toni ingenta. The following pills are

the public newspapers of the city of New York to the effect that she cured "irregularities or no charge, longest cases, ladies boarded, 213 East Seventy eighth Street," that she received into the house indicated a large number of women who were with child, and that she used instruments in producing abortions

The defendant was charged with maintaining a public nuisance under the provision of sections 385 and 387 of the New York Penal Code. The section concerned, so far as it was involved in this appeal, defines a public nuisance to be "a crime against the order and economy of the state, and consists in unlawfully doing an act, or omitting to perform a duty, which act or omission (1) annoys, injures or endangers the comfort of persons, or (2) offends public decency."

The defendant insisted that no crime under section 385 of the Penal Code was stated in the information, and that, therefore, the motions on the opening and closing of the case and in arrest of judgment should have been granted. There was no attempt to dispute that the defendant made admissions of the character above stated to the witnesses called by the people, but it was urged on the part of the defendant, that as section 294 of the Penal Code makes abortion a crime of a higher character, there was no jurisdiction in the trial court of the offense charged as a public nuisance. Great reliance was placed on the fact in support of this contention, that no adjudicated case had been found in which it has been held that the maintaining of a house for the purpose of practicing the vocation of an abortionist, constitutes a nuisance.

It is true, as a general proposition, the court says, that if a house is so kept that no one outside of its inmates is disturbed, annoyed or corrupted in their morals, it is not in law a disorderly house. The annoyance of corrupting influence must reach beyond the inmates and affect the public peace or morals of the community (1 Bishop on Criminal Law, Sec 1051), but the same author says that this doctrine should "not be so applied as to exempt any man from indictment, whose house is practically set open to the public, alluring the young and unwary into it for the purpose of their indulging in anything corrupting to their virtue, sobriety or general good morals. If a man would shield himself from indictment when he allows wicked and corrupting practices within his house he should keep his doors, while those practices are carried on, closed to the outer world" (Sec. 1053). Again, this same learned author says "If a house is of common resort for the commission of petty offenses against the laws, such as offenses punishable by fine, it is indictable on this ground, though not otherwise disorderly" (Sec. 1053). In the following section he declares that this principle is as old as the law itself, that "a man who holds out inducements for people to congregate, and together commit violations of a statute, not only lends the concurrence of his will to their wrongful acts, but also does what most powerfully tends to disrobe the body politic of her virtue and of the drapery of that order which the hand of government has thrown around her." In section 1057 he continues "To bring a case within this principle, the particular acts must be either indictable or, in some sense, unlawful. Therefore, the English court quashed an indictment which charged one with converting a house into a hospital for taking in and delivering lewd, idle and disorderly unmarried women, 'who, after their delivery, went away and deserted their children, whereby the children became chargeable to the parish.' 'By what law,' asked Lord Mansfield, 'is it criminal to deliver a woman when she is with child?'" In this there is a clear intimation that the indictment would have been good had it charged that the house was for the crime of abortion, rather than the lawful delivery of children.

Construing the provisions of the Penal Code under which this charge was made in the light of the common law, it is only a just construction to hold that the broad language used embraces the offenses of the common law rule. As before seen, the section defines a nuisance to consist in unlawfully doing an act which annoys, injures, endangers the comfort, repose, health or safety of any considerable number of persons, or offends public decency. This surely is as broad and inclusive in terms

as the rule of the common law, which has been made the subject of the code provisions. At common law it would have been, and under the code provisions it is, a nuisance for a person, by public advertisement, to invite and receive a class of the public to his premises for the purpose of violating the laws of the state, as was done in this case. Thus, in the court's opinion, constitutes "crime against the order and economy of the state" by offending "public decency."

It is the duty, therefore, of this court, in accord with law, to sustain this conviction. The offense of abortion is one thing, that of maintaining premises open to the public for the purpose of consummating that crime, is another and separate offense against the peace and good order of the state. It is an inducement to moral laxity and to crime, and is within the letter and spirit of the sections of the Penal Code here under consideration.

Throwing Pepper Not Attempt to Commit Mayhem.

The Supreme Court of Illinois says, in *Dahlberg vs People*, that mayhem (violently depriving another of the use of a member used in fighting), under the common law, while less inclusive than under the Illinois statutes, did include the striking out or blinding of an eye. The Illinois statutes provide that, whoever, with malicious intent to maim or disfigure, puts out or destroys an eye, etc., shall be imprisoned, etc. They also provide that whoever attempts to commit any of these prohibited by law, where no express provision is made by law for the punishment of such attempt, shall be punished, etc. The court does not think that an ineffectual effort to throw red pepper into another's eyes is an assault with attempt to commit mayhem. It does not think that the act of throwing red pepper is such a one as in the course of the usual and natural laws would, if uninterrupted, result in the crime of mayhem. But it says that it did not find it necessary to consider the question as to whether the defendant could be convicted of an attempt at mayhem if, when she threw the pepper, she thought she had employed adequate means, and intended to destroy the eyesight, when, in fact, she used inadequate means for this purpose. There was no testimony in the record tending to show that she so believed and intended, and while in criminal cases the criminal intention may be manifested by the circumstances connected with the perpetration of the offense without any positive testimony as to intention, it certainly could not be inferred because the defendant used inadequate means that she intended to use adequate means.

Damages for Pain, Especially from Injury to Toes

The Supreme Court of Arkansas says, in *St Louis, Iron Mountain & Southern Railway Company vs Snell*, a personal injury case brought by the latter party, that it is difficult for a jury to estimate the amount of compensation to be allowed for pain and suffering. It is an element of damages which is indeterminate in its character, and of which there is no exact standard of admeasurement. Jurors must exercise their judgment and discretion in fixing fair and just compensation for the injury. It is also a matter of great difficulty and of considerable delicacy for a reviewing court to determine whether or not the amount fixed by the jury is excessive. But there is a limit to the power of the jury, and, when the just limit is transcended by fixing an amount which is clearly excessive, the duty of the court is plain.

In this case the toes of the plaintiff, a child 6 years old, were mashed and bruised, and the skin was rubbed or scraped off. On the left foot the flesh was split about a half inch between two of the toes. No bones were broken or injured, and there was complete recovery in a few weeks, no permanent injury resulting. The witnesses testified that the injury was painful, and that the child appeared to suffer much therefrom, especially when the wounds were dressed. She had slight fever for several days, which the attending physician testified probably resulted from the nervous shock. As there was no permanent injury, mutilation or disfigurement of the child's feet, the only element of damages was the pain and suffering resulting from the wounds. The jury returned a verdict in favor of the plaintiff for \$1,500 damages.

The court entertains no doubt that the verdict in this case went far beyond the limit of just compensation to the plaintiff for the pain and suffering which she endured, and that the jury either misconceived the proper standard of measuring the damages, or were prompted by sympathy for the plaintiff to prejudice against the defendant. After careful consideration of the evidence it is convinced that it did not warrant a recovery of an amount exceeding \$750.

- 7 *The Eye and Ear Complications of Influenza C Graef New York

2 Malignant Diseases and Malaria—Kieffer concludes from his observations of the occurrence of malaria and cancer in Cuba and the Philippines that there is no real antagonism between malaria and malignant disease. Malarial infection supervening on malignant disease does not modify it. Natives of tropical countries have a relative immunity to malignant disease which varies widely. Adoption of civilized ways of life by natives diminishes this immunity.

7 Eye and Ear Complications of Influenza—Graef says that eye complications are comparatively rare in the course of influenza, while ear complications are frequent. The eye complications are conjunctivitis, inflammations of the lachrymal duct, corneal and lid herpes, and aching pains due to swelling of the lining of the frontal sinuses, embolic processes caused by mixed infections, iritis and glaucoma, as well as nervous disorders of vision. Ear troubles are acute middle ear catarrh and mastoiditis.

8 Immunity and Infection.—This is the fifth paper by Wright. In it he discusses the evidences of electrodynamic forces in the intracellular processes of growth and protection.

13 Bacteriologic Examination of Blood.—In order to have a permanent preparation of bouillon always at hand in a readily transportable form, McCaskey has had made an hermetically sealed tube, containing 100 cc with sufficient air space for agitation. These tubes, which are contained in a small pasteboard box, are permanent and when desired for use at the bedside the upper end of the hermetically sealed neck is easily fractured at the line of union with the cap, and the blood which should consist of at least 5 cubic centimeters freshly drawn from a superficial vein in a sterile syringe or through a sterile cannula instantly thrown into the bouillon and shaken up with it. In this way the bacteriologists are immediately diluted to such an extent that they will have no effect on the microorganisms. Even a few minutes' delay may cause failure. Accompanying the bouillon tube is a small

hermetically sealed tube, also with a breakable ring, which contains a sterilized rubber stopper which is immediately placed in the neck of the tube so that contamination will not occur in transit. In the bottom of the phial is also a sterilized pledget of cotton which replaces the rubber stopper as soon as the incubator is reached.

14 Ocular Pain in Influenza—Krall finds that there is an increasing number of cases of endemic influenza complicated by a sudden seizure of excruciating pain, located in the eyeball, lasting two or three days, unattended by symptoms of inflammation, while the eyeball and its appendages present a perfectly normal appearance. The diagnosis is neuralgia of the ciliary nerve due to toxins circulating in the blood acting on the nerve centers or fibers.

16 Unusual Symptom in Chorea—Price refers to the excessive secretion of saliva accompanied by drooling, which is not infrequently seen in all diseases characterized by marked motor disturbances.

19 Thrombosis of Cavernous Sinuses—Langworthy gives a detailed report of four cases that followed suppurative otitis media. In one case there was mastoiditis and facial paralysis as well as thrombosis of the lateral sinus, both cavernous sinuses and the internal jugular vein. The patient died from pyemia. The second case was complicated by an extradural abscess, the third case by bronchopneumonia, and the fourth case by meningitis. These three patients also died from pyemia. Langworthy urges resorting to immediate drainage in the treatment of these cases.

25 Sigmoid Sinus Thrombosis.—That sinus thrombosis may occur or be present in a patient who does not present the running ear, or the picture of mastoiditis, is shown by Holmes, who reports a case of this kind as a sequel of scarlet fever. An operation was done successfully, and the patient made a complete recovery in three weeks.

27 Diphtheria.—Roehr advocates the use of the microscope in diagnosing diphtheria, and advises giving large doses of antitoxin. In order to get rapid absorption and diffusion of the antitoxin he dilutes it with normal saline solution. He says that 3,000 units in one quart of normal saline solution will give as good results in one half hour as 20,000 units of undiluted antitoxin will give in six hours. The greater the concentration of the antitoxin the less rapid its absorption and diffusion. The fluid is injected subcutaneously or intravenously. Roehr reports four cases of diphtheria occurring in nurslings, the disease having been contracted from the mother.

 35 Foreign Body in Esophagus Removed by Aid of Esophagoscope. S. H. Large, Cleveland

29 Early Diagnosis of Gastric Cancer.—Thompson summarizes the conditions which combine to make operation not only justifiable, but desirable, as follows: 1 The patient's age should be within the average cancer developing period, for gastric cases, i. e., between 40 and 65 years. 2 There should be a rapid and decided loss of weight and strength, without other assignable cause, such as chronic gastric catarrh, neurasthenia, mental strain or worry, or chronic general disease, such as diabetes. 3 There should be evidence of some degree of stagnation of food contents in the stomach. 4 There should be failure to improve in marked degree under treatment, after a few weeks' trial. With these four conditions fulfilled, exploration should be seriously considered, despite the absence of gastric pain or other marked gastric symptoms. 5 A leucocytosis of from 12,000 to 16,000 with polynucleosis and a moderate secondary anemia, with low color index. 6 Decided dilatation of the stomach. With these two additional factors, operation is distinctly indicated. 7 Occasional attacks of vomiting, often without definite relation to food ingestion. 8 Occult or visible blood in the vomitus or stools. 9 Epigastric or right hypogastric rigidity and tenderness on deep pressure. The demonstration of hypoauidity or anacidity and the so-called carcinomatous cachexia are often wanting as early definite appearances, and are not always reliable.

30 Paresis.—Drysdale presents a complete study of 100 cases of paresis. It is evident that no two cases present the same clinical phenomena and that there does not exist during the developmental period any symptom that might be considered pathognomonic.

31 Mediastinal Tumor.—In the case reported by Lachty, the orthopnea, the cyanosis, and the edema of the arms, face and neck, were in marked contrast to the pallor and emaciation of the other parts of the body. The skin on the entire body was rather mottled or purpuric, if not copper colored. It was easily irritated, so that the patient was tempted to scratch it constantly. The diagnosis was somewhat in doubt, although the conviction began to grow as the patient was failing rapidly in strength that sarcoma was the most probable cause of the trouble. At the necropsy there was found a large tumor, weighing perhaps one or two pounds, occupying all of the superior mediastinum, surrounding and compressing the afferent and efferent vessels of the heart and both bronchi. Microscopically, the specimen had the appearance of a rounded sarcoma.

32.—See abstract in THE JOURNAL, March 23, 1907, page 1064.

33 Direct Transfusion of Blood.—Crile reports the results of his observations on the feasibility of direct transfusion of blood in pernicious anemia, leukemia, carcinoma, chronic suppurations, tuberculosis, pathologic hemorrhage accompanying jaundice, chronic hemorrhage from the bowel, surgical shock and a number of other conditions. The therapeutic results are grouped into three classes: positive, negative and undetermined. Among the positive results is transfusion in acute hemorrhage, which is apparently final. In pathologic hemorrhage it has proved positive in improving the patient's immediate condition, and in most instances wholly controlled the hemorrhage itself. In shock its value seems far greater than any other remedy which he has hitherto employed. From the experimental standpoint it seems to be the most effective treatment of illuminating gas poisoning. Among the negative results are transfusion in pernicious anemia, leukemia, carcinoma, strychnin poisoning and diphtheria toxemia. Among the undetermined results may be mentioned chronic suppuration with its attendant debility and anemia, tuberculosis and the acute self-limited infectious diseases.

Of the seventeen clinical cases, all were technically successful. In every instance the donee experienced a heightened vitality and in the absence of serious organic disease the patient became buoyant even jocose. Some had chills during transfusion or soon after and a majority showed some febrile reaction later. In the case of serious disease, such as sup-

puration, pernicious anemia, leukemia, the improvement in the blood picture was not maintained, as in patients having no serious disease or infection. Preliminary notes on this subject were published in THE JOURNAL, July 21, 1906, page 189, and Nov. 3, 1906, page 1482.

 44 Medical Charities of Manhattan and The Bronx. F. L. Lattimore, Philadelphia
 45 History of the Medical Society of the State of New York. J. J. Walsh, New York

39 Vulvovaginitis in Children.—Goffe reviews this subject generally, and urges a campaign of education to prevent the occurrence of this condition.

40 Scratching in Skin Diseases.—Ruggles comments on the rôle played by scratching in the production and continuance of skin diseases, and urges that to treat such cases successfully it is necessary to employ measures which will take the patient's mind away from the desire to scratch. That is, abstinence from scratching is the real therapeutic measure, without it the skin disease will persist indefinitely.

41 Radical Treatment of Middle Ear Caries.—Cott urges the institution of radical treatment of caries of the middle ear, and presents a résumé of 62 cases.

42 Pronation of Foot.—Berry calls attention to the fact that pronated foot is the first stage of a progressive weakness and deformity, that it is often overlooked or neglected, and that it can readily be relieved by proper treatment. It is necessary, first, to correct the tendency to deformity, and second, to strengthen the foot, thus curing the tendency to deformity. The use of a brace and a well selected course of gymnastics are the means employed in the treatment.

- 46 Influence of Flesh Eating on Endurance. I. Fisher, New Haven
 47 Lumbar Lordosis. M. S. Marcy, Peoria, Ill.
 48 Liquid Air in Dermatology. J. D. Gold, Bridgeport, Conn.

46 Influence of Flesh Eating on Endurance.—Fisher's experiments indicated that the users of low proteid and non-flesh dietaries have far greater endurance than those who are accustomed to the ordinary American diet. Of the three groups compared, the large flesh eaters showed far less endurance than the abstainers, even when the latter were leading sedentary lives.

48 Liquid Air in Dermatology.—Gold says that there is no doubt that liquid air is of decided benefit and that a cure with superior cosmetic effects in pigmented nevi, warts and vascular nevi may be affected with less pain and fewer applications than with caustics or electrolysis. In epithelioma it is of doubtful use. In lupus erythematosus the results obtained have been so encouraging, he states, as to warrant a further trial of the agent.

57 Ideal Cholecystotomy J H Smart, Dallas.
58 President's Address of Dallas County Medical Society A W Carnes, Hutchins.

50 Intussusception—Lynch reports a case of intussusception which illustrates the difficulty of making a correct diagnosis at an hour sufficiently early to overcome a fatal issue. He concludes his paper as follows: 1 In some cases of intussusception pathognomonic signs may not appear until it is too late for a successful result through laparotomy. 2 A laparotomy would be easy if done in the early hours of the disease, before much swelling occurs, adhesions form, or the bowel becomes gangrenous, and that the risk could not be much greater than in an ordinary laparotomy under the same aseptic precautions. 3 Forty eight hours, or even twenty-four hours, can not with safety be set as a time limit for the beginning of a radical procedure in the face of an improvement, or the failure of relief by other means. 4 The excessively high mortality in intussusception is due, in most part to late surgical interference. 5 Only low invaginations are likely to be reduced by hydrostatic pressure, and it should only be tried in the very early hours of the disease, and in some invaginations, especially high ones, it may be misleading and harmful in that class of cases in which improvement is apparent, and a second paroxysm is certain if reduction is incomplete. 6 All patients with intussusception should be operated on in the first twelve or sixteen hours of the disease when a diagnosis is possible, and it is not certain that reduction has been accomplished by other means. 7 In any form of obstruction, except fecal impaction, when there is a doubt in diagnosis, an exploratory laparotomy should be advised. 8 In proper hands and with the proper technique an early exploration in the acute obstructions would increase the chances of recovery in all these conditions (except fecal impactions), and reduce the mortality of intussusception to a minimum.

52 Value of Gastric Analysis—Cook says that together with the history, symptoms and physical examination, gastric analysis gives additional information by which we are able to make clear the clinical picture, place the case in its proper class and institute a logical and rational method of treatment.

53 Oxylchlorid of Copper by Cataphoresis—Anderson uses this agent in the treatment of granulated lids in lieu of the sulphate of copper pencil. The oxylchlorid is liberated by electrolysis in the application to the reverted lid of a copper electrode. It shortens the time of treatment, there is not much loss of epithelium, the intervals between treatments may be greater and the results are more permanent than from the use of the sulphate.

54 Nephrotomy and Nephrectomy—The patient whose case is reported by Bari and Goldstein is alive and well, eighteen months after the operation.

61 *Studies from the Bacteriologic Laboratory H Fox, Philadelphia.
62 *Effect of Light on the Development and Staining of Ova in Eosin Solutions L P Shippen.

60 Antiseptic Power of Salicylic Acid—Wood found that although both the air bacteria and the pure culture of colon bacilli were destroyed after one minute's exposure to a 0.5 per cent solution of salicylic acid, a 2 per cent solution of sodium salicylate was ineffectual even after two minutes' exposure. Strontium salicylate gave the same results as did sodium salicylate. The neutralization of benzoic acid gave the same results as salicylic acid. A 1 per cent solution of sodium salicylate prevented the development of microorganisms.

61 Studies from Bacteriologic Laboratory—Fox records some observations made on three members of the Bacterium

mucosus capsulatus group, and publishes a brief note on the effect of toxin and antitoxin injections on the phagocytosis of diphtheria bacilli.

62 Effect of Light on Ova.—Shippen summarizes his findings as follows: 1 Eosin inhibits the development of ova and injures the motility of gastrulae and blastulae, and in time kills them. 2 Light has an additional injurious effect on the development of ova and the motility of larvae in eosin solutions and shortens the life of the blastulae and gastrulae. 3 Certain parts of living organisms can be stained by eosin. It is very probable that the cells of living organisms which take up eosin are dead or dying. Eosin enables us therefore to recognize dead or dying cells in living organisms. It is, further more, of interest that cells which take up eosin may be entirely surrounded by a layer of living cells.

72 *Substrate for Potato as a Culture Medium P G Heinemann, Chicago.

65 Purpura Hemorrhagica—LeCount and Batty describe the clinical, bacteriologic and anatomic findings in a remarkable case of infection with the paratyphoid bacillus in a woman of 36. The clinical course appears to have run over a period of about two months. A prominent clinical feature was the appearance of bluish and purple blotches on various parts of the body. The autopsy showed hyperplasia of the intestinal lymph structures, mesenteric, retroaortic and iliac lymph glands and of the spleen, hemorrhages in the urinary tract, and in the kidneys large gray and grayish red areas especially in the cortex and about the bases of the pyramids. The bacteriologic examination resulted in the isolation of a paratyphoid bacillus. The areas in the kidney and the swelling of the lymphoid structures were found to be due to an accumulation of large endothelial cells, often with more than one nucleus. Accumulations of these cells were also found in various other organs. The process in the kidney resembled the acute interstitial nephritis that occurs in scarlet fever but did not show the plasma cells characteristic of the latter.

66 Systemic Blastomycosis—LeCount and Myers describe the termination and the postmortem findings of the case of systemic blastomycosis reported by Fisendath and Ormsby in THE JOURNAL A M A, Oct 7, 1905, p 1045. This case concerns a man of 33, presenting the symptoms of generalized blastomycosis, with most pronounced localization in the skin, subcutaneous tissue and lungs, and in whom there developed after some time, a gibbus opposite the fourth dorsal vertebra with subsequent paralysis, death occurring two years and a half from the onset. After death there was found a blastomycotic bronchopneumonia, blastomycosis of the peribronchial lymph nodes, the pleura, retropharyngeal tissue, liver, kidneys, colon, dorsal vertebrae, spinal dura and cerebellum, elbow, knee and ankle joints, and also of the skin and subcutaneous tissue in which there were ulceration, fistulae and scars. In the cerebellum there was a conglomerate blastomycotic nodule in which the organisms present in large numbers in all the lesions appeared to be reproducing themselves by sporulation. So far sporulation has been regarded as not taking place in the tissues in blastomycosis which differs in this respect from the coccidial disease of California, an outstanding feature of which is the large number of sporulating fungi in the tissues. In this case there was also a definite blastomycotic focus in a peribronchial lymph gland. The colon was the seat of certain remarkable nodules which the authors regard as blastomycotic in spite of the failure to find in them blastomycete. The case shows that as the

observations of systemic blastomycosis multiply, new anatomic localizations and other features are constantly being added to those previously recorded

68 Diphtheria—Albert's article deals with statistics and is not readily abstracted. It will, however, interest health officers, because it describes the method of the Iowa State Board of Health in dealing with the diagnosis and quarantine of diphtheria

70 Trypanosomes.—This is an extensive study of the occurrence of trypanosomes in mosquitoes and other biting insects, the results being of great value in the study of the role of these insects as harbors of diseases due to flagellates

71 Streptolysin—Ruediger here presents additional facts concerning the nature of streptolysin, the complex substance produced by streptococci and able to cause laking of red corpuscles, extending the observations previously made by him. He shows that it is intimately associated with the globulins, from which it has not been separated. Various normal sera have marked antistreptolytic properties, but attempts to produce a specific antistreptolysin did not succeed

72 Substitute for Potato as Culture Medium—Heinemann's artificial potato medium is made as follows: Fifteen grams of agar are dissolved by heat in about 600 c.c. of water. To this is added 200 c.c. of a watery solution of

Asparagin	5 grams
Dipotassium hydrogen phosphate	2 grams
Disodium hydrogen phosphate	2 grams
Magnesium sulphate	2 grams
Calcium chloride	2 grams
Ammonium lactate	2 grams

Ten grams of peptone are then added and the mixture filtered after the reaction has been made neutral with phenolphthalein. To this solution is added 30 grams of washed starch in suspension and the mixture heated to near the boiling point. The total should weigh 1,000 grams. The medium is now tubed, sterilized in the autoclave for five minutes at 120 C, and cooled in a slanting position. The advantages of this medium over ordinary potato are: Constant composition, adjustable reaction to suit various purposes, presence of starch and other substances found in potato in highly assimilable form

- 2 *Treatment of Surgical Tuberculosis F J Steward
- 3 *Vaccine Treatment of Tuberculosis in Children C Riviere
- 4 *Influence of Antituberculous Serum on the Opsonic Index W C Bosanquet and R E French
- 5 Relative Opsonic Power of the Mothers Blood Serum and Milk E Turton and R Appleton

1 Ileocecal Tuberculosis.—Hartmann is of the opinion that this form of tuberculosis occurs more frequently than is generally recognized, and that, moreover, when suitable treatment is followed, patients thought to be incurable may be cured. Hartmann has made seven resections for tuberculous disease, with only one fatality, and that occurred before 1900. In the hyperplastic form of cecal tuberculosis he advises resection. In the enteroperitoneal form, or when with a hyperplastic tuberculosis there is an extensive mass of adhesions, he says that the exclusion of the disease is indicated. Usually unilateral exclusion is sufficient. Hartmann reviews 229 cases reported in the literature

2 Treatment of Surgical Tuberculosis.—At the conclusion of this paper, which deals with the subject in the usual manner, Steward reports a case of tuberculous disease of the right kidney and the bladder, in which all the usual methods were tried, without any sign of arresting the progress of the disease, and in which under treatment with tuberculin, apparently complete cure took place

3 Vaccine Treatment of Tuberculosis.—Riviere has treated a number of cases of tuberculosis, such as tuberculous dactylitis, superficial abscess, tuberculous glands, tuberculous joint disease, psoas abscess, abdominal tuberculosis and phthisis, with tuberculin under opsonic determination. He believes that tuberculin is a most valuable remedy for such patients, especially if nutrition is not greatly impaired. With proper dosage a steady improvement occurs both in the local conditions and in the general health. Even the secondary infection lessens severity. He urges, however, that the treatment should be undertaken by none except those who have given it special study

4 Influence of Antituberculous Serum on Opsonic Index.—From an analysis of five cases, Bosanquet and French conclude that a series of daily doses of Marmorek's antituberculous serum will, when administered by rectum, usually produce a rise in the tuberculo opsonic index. This rise begins after the first three or four doses and soon reaches a maximum, close to which the index remains for three or four weeks, while serum is being given, and does not fall till nearly a week after injections have been omitted. This rise in the opsonic index is coincident in some cases with an improvement in the general condition of the patient and a diminution of the diurnal variation of the temperature. Subcutaneous injections of the serum do not seem to have such a good effect

9 Treatment of Tuberculosis and Leprosy.—Wernich publishes a preliminary note on the successful treatment of tuberculosis and leprosy by means of an albuminoid metabolic product, chemically altered, of a bacillus, discovered at Boshof,

Orange River Colony, in 1898, as a practically pure growth in an infusion of an herb that was suspected to contain an alkaloid. Thus far three classes of cases have been treated successfully, tuberculosis of the lungs and glands in the neck, tuberculosis of the skin, and leprosy. The material is administered by the mouth, air dried and pulverized, when the stomach is empty, and usually with a little sodium bicarbonate. The method of obtaining the powder used is described in full. The paper is to be continued in the next issue.

15 Onchocerca.—This is a disease that occurs among the blacks of Central Africa, and thus far has not been seen in the white race. The face usually is swollen and painful and there is bleeding from the mouth. Situated in the hard palate and buccal mucous membranes are vesicles distended with blood, ranging from a quarter to a half inch in diameter. Usually, also, there is hematuria. The disease is regarded by the natives as very fatal, but Massey has treated a number of these patients with bicarbonate of soda in large doses, 40 grains, twice a day, and no fatalities have occurred.

25 Endothelioma.—During a period of four years Lazarus Barlow examined microscopically a large number of malignant tumors, of which endothelioma constituted 8 per cent of the malignant diseases of the tongue, 10 per cent of the uterus, 10 per cent of the breast, 10 per cent of the liver and bile passages, and 7 per cent of the malignant diseases primarily affecting bone.

26 Blue Pigmentation of Tympanic Membrane.—Love has seen half a dozen cases in which the tympanic membrane was discolored in the manner so often seen when gunpowder is in grained into the skin as the result of an explosion. This pigmentation was associated with deafness or tinnitus, and with thickening or alteration in the curve of the drum membrane. The pigment was on the inner side of the membrane and therefore, must have reached it through the Eustachian tube.

33 Protection of Rheumatic Children.—According to Hawthorne, the one influence on which we can depend for the prevention of heart disease in rheumatism is absolute rest so long as the rheumatic poison shows signs of activity.

35 Gout in Parent and Child.—The child, in the cases reported by Jones, did not present any evidence of gout until

she was nearly 6 years of age, when the mother noticed a fullness in the neck that had increased fairly rapidly at first and then more slowly. Except that there was no pulsation the tumor was identical with the goiter of exophthalmic goiter. Under treatment with thyroid extract, the tumor began to shrink, until after about ten weeks, the thyroid became of about normal size, and it has remained so ever since. No other treatment was employed, beyond attending to the general hygiene of the patient. The mother of this patient had had a goitrous swelling, evidently an adenoma, for about eight years.

37 Epilepsy in Children.—Nageotte describes various manifestations of incipient epilepsy in children. They were observed almost invariably after some severe acute infection which had evidently induced a slight encephalitis. The majority of such children recover completely in time. A child may become an idiot or may present hemichorea after an attack of whooping cough, and this masked epilepsy belongs in this same category. In one case a child of 5 seemed frequently startled. Whatever she was doing she stopped at times for a moment and then went on. No one noticed this at the time, but gradually epileptic seizures followed. They yielded to doses up to 2 gm (grains xxx) of bromids, and the child is now well. She had previously passed through several infectious diseases. Another child, a girl, had suffered from enteritis and scarlet fever and it was noticed that she grew absent minded at times in her play. An epileptic seizure gave the alarm, and recovery was soon complete under the bromids. In this child the knee jerk was absent but she was unusually intelligent. A third type of incipient epilepsy assumes the form of spells of anger. The child throws himself on the ground, the eyes open. In one such case by the end of a week the eyes had a haggard expression and an epileptic seizure occurred. This type, Nageotte states, also subsides as a rule under the bromids. There is no loss of consciousness in these early manifestations of epilepsy, the trouble being more choreiform in character. The fact that the tongue is not bitten does not exclude epilepsy. Incontinence of urine at night may be an accident, but more often it is a nocturnal seizure. Comby believes that essential epilepsy is very rare, as a rule, the trouble can be traced to some preceding acute infection.

38 Dangers of Insufficient Nourishment for Infants.—Variot asserts that an infant should take one seventh of its weight as its daily ration during the first few months. As there is not much difference in the amount of calories in human and cow's milk, the amount of each should be about the same. Defectively developed infants require even more food than the healthy in proportion. He has made a practice of watching the development of infants on a certain ration and has thus established the average ration of one seventh of the weight. With less than this the infant suffers from insufficient nourishment. In one case a infant vomited and was losing weight. The mother had very little milk. He gave the child sodium citrate to stop the vomiting and doubled the amount of milk given, from 300 to 600 gm (9 to 18 ounces), and the child began to thrive at once. Loss of weight and vomiting are among the signs of insufficient nourishment but this subject of nutrition in infants has not yet received the attention it deserves.

39 Hypnotism in Treatment of Onanism in Children.—Régis relates 2 cases in children of 6 and 7 years of age.

inconstant masturbation for 2 or more years. After failure of all other measures, perseveringly applied, suggestion under hypnosis cured the younger child, a girl, but the boy resisted even this. Mechanical measures had been tried by the parents for a long time, and Régis thinks that these are directly injurious, accentuating the tendency and rendering it more chronic.

40 Antisepsis After Accouchement.—Lucas Championnière orders that the vulva should be bathed with a hot and strong solution of 50 gm (3iss) carbolic acid, with the same amount of glycerin, in a liter of boiled water. In case of any excoriation the following salve is applied: 100 gm (3iii) vaselin, 10 gm (3iiss) boric acid, and 1 gm (15 grains) balsam of Peru. The vulva is then covered with a compress dipped in a weak solution of carbolic acid, and wrung nearly dry. The toilet is repeated morning and evening with this hot, weak carbolic acid solution except in case of severe vulvar lesions, when a small quantity of a stronger solution can be used.

41 Systematic Preventive Antisepsis for School Children.—Weber states that for some time he has been applying the principle of preventive antisepsis of the nose and mouth as a routine measure in his private practice. He here advocates it on a large scale for children in school, saying that the benefits in private practice have been established beyond discussion. He reviews the arguments in favor of the assumption that all the acute eruptive fevers are essentially a lymphangitis. Glandular affections in the neck can often be traced to an apparently insignificant follicular tonsillitis, and the mouth of Stenson's duct shows a reddish circle in case of mumps, resembling the aspect of a stitch hole abscess, and having the same significance. "How frequently," he remarks, "do we observe an ordinary cold develop, then comes sore throat, followed by a tracheo-bronchitis and, later, a tuberculous process in the lung?" "Daily antisepsis of the upper air passages may ward off all these bacillary infections." He, therefore, urges study of the most practical means to accomplish this end, suggesting that great benefit would certainly follow if school children were trained to wash their hands with soap before taking their places in school, as the hands are the usual vehicle of the "living dust." Each child should also be trained to introduce into each nostril a small amount of some antiseptic salve, and also to gargle with some good antiseptic or to suck an antiseptic tablet, possibly with sulphur for the base.

43 Intermittent Albuminuria.—Gillet discusses the albuminuria observed without other signs of nephritis. It may be the result of some lesion in the kidney, but the prognosis, he states, is essentially favorable. The absence of tube casts and of arterial hypertension is a special feature of this form of albuminuria. The unimpaired permeability of the kidney and the arterial hypotension are prominent characteristics of this form, as likewise, although less important, the orthostatic and intermittent character of the albuminuria.

44 Epistaxis as First Sign of Hemorrhagic Purpura.—Escat describes 4 cases of hemorrhagic purpura which developed with a peculiarly insidious chronic and latent course, recurring epistaxis being the only sign to attract attention. This should always compel examination of the body of a child in search for ecchymoses, as the purpura is liable to develop unsuspected. In the cases of death from recurring epistaxis on record, many of the children may have been affected with this unsuspected form of this disease. In one of the 4 cases described the patient was a lad of 15 who had had severe epistaxis several times a day for a month. The physician had tamponed the nose and a rhinologist had cauterized the nasal mucosa, but no one had made a general examination. Escat found the body covered with "bruises" as the boy called the numerous ecchymoses observed for several weeks. He was small for his age and intensely anemic, the skin was shiny, with a grayish pallor and greenish reflections, but the boy had no fever or other general symptoms. Long cotton wicks, dipped in 1/5 000 adrenalin were inserted in each nostril and renewed every 12 hours, while 2 gm (30 grains) of calcium chlorid was given internally. The patient soon recovered under this treatment. The history of another case in a girl of 10 was about the same. The third patient was a child of 3, and epistaxis had

recurred two or three times every day, as a rule, during 15 months. The petechiae observed occasionally were attributed by the parents to bruises. The fourth patient was a child of 6 with recurring severe epistaxis, the mother stated that for three years she had noticed a tendency to extensive ecchymosis on the slightest contusions. The child had an extraordinary appetite, and the mother stated that during her childhood she had been subject to the same tendency to ecchymosis on the slightest provocation. Escat suggests that the chronic character of the purpura in these cases seems to show a close connection between hemorrhagic purpura and hemophilia. Further research will throw light on the question, especially if greater attention is paid to the latent and "walking" forms of hemorrhagic purpura. Rhinologists, especially, should be on the alert to detect it when consulted for recurring epistaxis.

50 Cancer of the Pancreas and Diabetes.—Brault reports a case in which the diagnosis wavered between total cancerous degeneration of the pancreas with symptomatic glycosuria, and cancer with coexisting or preceding diabetes. Autopsy showed that the first assumption was probably correct. The amount of sugar in the urine ranged from 115 gm to 340 gm, but averaged 150 gm toward the last, finally subsiding gradually to zero just before death. The patient was a hearty eater, and this is the probable explanation of the glycosuria observed.

51 Ionization in Treatment of Ankylosis and Sclerosis.—Desfosses has had much success in the treatment of ankylosed joints by means of electric ionization. His experience confirms that of other workers in this line, demonstrating the superiority of the method to massage and other measures in respect to the resolution of ankyloses. The most efficient substances to date in his experience have been a 2 per cent solution of sodium chlorid or sodium salicylate. The best results have been obtained with electrodes covering a space of 100 or 200 sq cm with a current ranging from 50 to 80 milliamperes, and the sitting lasting for half an hour to an hour. The ankylosis seems to be most readily influenced when of traumatic origin, next in order come the post-infectious ankyloses and last the post-rheumatic. The cathode is applied to the part to be treated. He adds further that cicatrices from burns are effectually influenced by ionization and that the pain of a sprain is reduced.

60 Water Treatment of Membranous Croup.—Sadger reviews the history of hydrotherapy of membranous croup, many remarkable cures having been reported by various writers, commencing with Harder in 1821. The aim seems to be to induce powerful revulsion by sudden douches with cold water, and he urges the revival of the method. Winternitz believes that there is a paresis of the posterior crico arytenoid muscles which can be conquered by a powerful reflex thermic and mechanical stimulus affecting the respiration center. He reports 4 cases in which this treatment was successfully applied. The body was rubbed with sponges dripping with water at 10 C. (50 F) for 6 minutes. While this was being done the head and back of the neck were repeatedly doused with cold water from a height, with packs in the interim, until pulse and temperature were nearly or quite normal. Bartels of Kiel has applied the water treatment in a number of severe cases with great benefit, as an adjuvant to intubation or tracheotomy. In case the temperature is low, the child is placed in a warm bath before being given the cold douche. In the cases reported large amounts of the false membrane were coughed up and expelled through the tracheotomy opening. Sadger in conclusion quotes Priessnitz saying that "water treatment takes character." This applies to the physician as well as to the patient, and half hearted measures do more harm than good. One writer reported that in 10 years of experience with water treatment all his 28 little patients with membranous croup recovered under it. He repeats the douche whenever the breathing becomes difficult and the croupy cough recurs. In the severest cases, with much fever, he cools off the body by sponging before he attempts the douche. The latter can then be applied without fear, he says. The cold water must be doused suddenly over the head, then over the back of the neck. This causes such a shock that the child takes sudden, deep inspirations and struggles. At first he repeated the douches every hour, in very severe cases, leaving the child in the water for 10 minutes during the first 2 or 3 douches. After the fifth or sixth douche the child is generally so much improved that it asks for food. After each douche the child generally falls into a refreshing sleep. The full details of the older writers on this subject are given *in extenso*, and Sadger adds that the re introduction of hydrotherapy in the treatment of croup will certainly increase the proportion of recoveries.

61 Rational Feeding of the Child from Birth to Two Years Old.—Klose's article won the prize presented by the Soc. Scientifique d'Hygiène Alimentaire et de l'Alimentation rationnelle de l'Homme à Paris. It presents in detail and in tabulated form the principles of infant feeding followed in Koht's service at the clinic for children's diseases at Strasburg, and the results observed. He compares them with those obtained elsewhere. The Theinhardt and Biedert mixtures are used as adjuvants to mother's milk in some cases. The infant mortality at Strasburg is about 10 per cent.

63 Gastrointestinal Hemorrhage in the New Born.—Shukow sky has observed 20 cases in his own practice. He reviews the history of the subject and states that in 18 of his cases the hemorrhage was rapidly fatal. Gelatin proved promptly successful in certain cases, but it failed completely in the cases of acute hemorrhagic gastroenteritis and of syphilitic dyscrasia. Even the apparently most desperate cases may suddenly take a turn for the better. Mercurial treatment is indicated on suspicion of syphilis. He has witnessed recoveries under chlorid of iron, one drop in a teaspoonful of gruel, milk or sweetened water. Some authorities give it every half hour, others give one fourth or one half drop in water every five minutes. In one case a well developed child, free from trauma or syphilis, passed bloody stools and vomited blood. The abdomen was bloated, the temperature high. Gelatin was administered with out effect, and lavage of the stomach was then resorted to. The stomach was rinsed out with cool physiologic salt solution (54 F) three times, with a few minutes' interval. The effect was astonishing in this as in a second similar case. Vomiting ceased at once and the children went to sleep and did

not wake for twelve or fourteen hours. The stomach was rinsed out again when they woke, and the intestines were flushed with the cool salt solution at each lavage. He had been impressed with the idea of a possible gastrointestinal infection in such cases by the discovery of acute hemorrhagic enteritis in some of the children who had previously succumbed. The coolness of the fluid used in the lavage has a tendency to reduce the supply of blood in the parts. The remarkable promptness of the effect in both these severe cases was impressive. It removed from the gastrointestinal tract the decomposing masses of blood and the bacteria and toxins contained in them. The discovery of severe inflammatory gastrointestinal processes as a not infrequent finding in infants only a few days old justifies prompt lavage of the stomach and intestines in severe cases of melena in the new born. Autopsy of 4 of the infants revealed extensive hemorrhages elsewhere, but none in the stomach or intestines, although a quantity of blood had been swallowed. In the 14 other fatal cases, autopsy in 12 revealed syphilis, tumor formation, hemorrhagic pneumonia, or hemorrhagic inflammatory processes in the stomach and intestines. Examination of the clots obtained by lavage in the 2 cases mentioned showed staphylococci and streptococci besides other micro organisms. No medical measures were attempted in one of these cases beyond the lavage.

65 Two Fatal Cases of Chorea.—The 2 patients were girls of about 12, and the disease came on abruptly, with extremely violent motor agitation, high fever with unconsciousness, hemiplegia and death in 6 and 13 days. In both cases there were evidences of recent endocarditis and acute enlargement of the spleen, tending to show that death was due to some general infection. Opportunity for infection was obvious in numerous erosions observed on the body. The 2 cases occurred within five months of each other, and were the only fatal cases of chorea known in 175 cases of chorea observed at Moscow for many years. The brain substance was soft, scattered with drops of blood, but no inflammatory focus could be detected.

66 Tumor in Cerebellum in a Child.—Oshima's patient was a girl of 6 who gradually exhibited symptoms of a tumor in the brain, pain in the back of the head, accompanied by vomiting, evening and morning, such as is frequently observed with tuberculous meningitis. Loss of consciousness, disturbance in vision to actual blindness, grinding of the teeth, uncertain gait, apathy, loss of appetite and emaciation were the principal manifestations. A large tubercle was found in the cerebellum, with two smaller ones in the cerebrum.

68 The Heart in Scarlet Fever and Under Serum Treatment.—Trotzky accepts as established the theory that the heart is affected constantly in case of scarlet fever, feeling the influence of the scarlet fever sepsis or of its products from the first rise in temperature until convalescence passes into complete recovery. The intensity of the epidemic and the severity of the disease do not seem to have any direct, immediate influence on the intensity of the functional disturbance. Although these functional disturbances are not directly dangerous, yet in time they are liable to induce in the child's organism such deviations from the normal as to interfere decidedly with physiologic, physical and mental development. The murmur at the apex and arrhythmia of various kinds are the signs of the functional disturbances most commonly observed. Subcutaneous administration of serum induces abrupt changes in the sphygmographic tracings showing unmistakable changes in the action of the vascular system. Only 23 of the 43 patients in his service recovered in the last epidemic. The ages of the patients ranged from 9 months to 13 years. In the fatal cases arrhythmia was pronounced, the pulse being highly irregular and thready. The signs of congestion in the skin and mucosae grew more and more pronounced, and the children died in coma. Study of the cases with a favorable termination showed that the pulse was monocrotic, sometimes dicrotic or hyperdicrotic, the arterial pressure corresponding to the age of the child. After injection of serum, the pulse was always monocrotic, irregular, uneven and the blood pressure rose a little. He regards this as indicative of acute transient relaxation of the vessel walls. After the serum has been absorbed the pulse returns to its previous condition, but with low waves and the blood pressure remains high.

69 Gelatin Treatment of Melena in Infants.—The mother of the infant in the case reported was a primipara with moderately contracted pelvis. The child, a male, was delivered with forceps after 36 hours of labor. He was asphyxiated, but soon revived, and seemed to be perfectly healthy until the fourth day, when slight icterus developed, and he vomited fluid and coagulated blood twice. Ten cc of a 2 per cent solution of gelatin was injected under the skin on each side of the back. The child vomited blood again and passed blood in its stool and the same injection was repeated toward night. The next day there was no vomiting, but the stools were blackish, and 10 cc of the gelatin solution was injected again about noon on the fifth day, after which the child developed and nursed normally. During the period of melena he was kept in an incubator as his temperature was subnormal. He weighed 2,770 gm at birth, and 2,800 gm by the twenty sixth day.

72 Operating Table.—Bumm's table is distinguished by its simplicity. The end of the table is raised or lowered by means of an oil pump worked by a pedal. The piston of the pump and a single leg at the head of the table are its only supports. Its chief advantage is claimed to be that the field of operation can always be adjusted at the same level.

77 Artificial Vagina Made from Loop of Ileum.—Häberlin discusses the present measures for making an artificial vagina in case of complete absence of a normal vagina, and describes a case in which the best efforts failed to produce a permanent vagina and in which a wife was divorced on this account. As cases of the kind are rare, he urges those who have the opportunity to try a new technic which he suggests, and presents a number of arguments that theoretically establish its usefulness. A recess is made in the perineum for the new vagina. The abdomen is then opened and a piece of the lower part of the ileum was resected for about 15 or 20 cm. (8 or 9 inches). The intestine is then reunited. The central end of the resected portion is then sutured, the distal end is closed with a clamp, and the whole is pushed down past the bladder until it emerges in the opening in the perineum. The cervix is implanted in a side opening into the resected intestine. In case of total absence of the uterus the resected portion is merely drawn down into the recess made for it and is sutured to the outer opening. The abdomen is then sutured and the new vagina drained. In experiments on the cadaver and in other operations in the clinic, Häberlin has tested the stretching power of the mesentery of this part of the intestine, and has found that it will stand extreme traction without interference with its vitality.

79 Classification of Contracted Pelvis.—Balsch writes from Döderlein's clinic to urge classification according to the size of the true conjugate diameter not according to the shape of the pelvis. The size of the true conjugate is what determines the

prognosis. He regards 7 and 7.5 cm as the limit for a viable child at term, calling this the second degree of contracted pelvis. The first degree includes all down to 8 cm and the third degree all between 7 and 5 cm. The children are usually smaller with generally contracted pelvis than with flat pelvis.

80 Prophylaxis and Treatment of Headache After Spinal Anesthesia.—Offergeld has applied this method of anesthesia in 40 maternity cases, and 22 of the patients suffered from more or less severe headache afterward. He found it possible to arrest the headache almost immediately by withdrawing a little of the cerebrospinal fluid by lumbar puncture. This clinical experience was explained by experiments on rabbits. The findings demonstrated beyond question that the headache is the result of increased pressure in the spinal canal. By allowing the escape of 1 or 2 cc of the fluid before making the injection and restricting the amount of fluid injected to the minimum, it is possible, he thinks, to obviate all trouble from this source. In case the headache develops, it is possible to cure it at once by lumbar puncture, thus relieving the pressure. This measure never failed in his experience, all headache vanishing in from 30 to 40 minutes at latest.

84 External Esophagotomy for Removal of Foreign Bodies.—Naumann adds 28 new cases to the list of 326 cases collected by Balacescu in 1903, with a further list of 12 similar operations performed in his service at Zwickau.

85 Cicatrix-Forming Action of Slices of Thyroid Gland.—Navratil's article issues from Dollinger's clinic at Budapest, and supplements his communication of a year ago relating the remarkable action of the thyroid gland which he had sutured over an opening in the esophagus first closed with a tobacco pouch suture. The upper pole of the thyroid gland was not disturbed, but the lower pole was drawn slightly to one side to fit over the sutured wound. The thyroid tissue displayed such marked clinging and cicatrix-forming properties in this case that he has since experimented with isolated slices of thyroid gland, and found that they are equally efficient in this respect, growing intimately into the tissues in a very short time and retaining their vitality indefinitely. His experiments were made on dogs.

86 Gastroenterostomy.—Delaloye reviews the experiences with this operation at Feurer's clinic at St. Gallen, a total of 117 cases. The number of gastroenterostomies for cancer is growing constantly less, as the conditions are so much better after resection of the pylorus that this is preferred whenever possible. The mortality after resection has been only 16.66 per cent of 42 cases, and zero in the last series of 20. The mortality of the gastroenterostomies was 25.64 per cent. The cause of death was the vicious circle in 4 cases, pulmonary edema in 1, hemorrhage from gastric ulcer in 1, pneumonia in 5, peritonitis in 8, and marasmus in 10 cases. The peritonitis was due in 4 instances to gaping of the wound.

90 Treatment of Fracture of the Calcaneus.—Ideal functional results are reported by Becker in a case of fracture of the calcaneus treated by repose and ice for ten days, after which the fracture was reduced by means of an elevator driven perpendicularly straight across the bone, close to its

under surface, toward the inner margin of the foot. The handle of the elevator was then lowered, thus bringing the point close under the internal malleolus, where it emerged through a small incision. With traction on the handle and on the point of the elevator, the fractured bone was brought into place, and while an assistant held the parts in this position Becker introduced a drill from behind, passing upward through skin and bone along the median plane of the calcaneus. The exact distance had been calculated with the Roentgen rays beforehand and marked on the drill, so that it stopped just short of the extreme end of the bone, thus not emerging into the joint. He left the drill quietly in place as a support for the parts and did not remove it for six weeks, when, after chiseling off a projecting piece of bone from the lower surface of the calcaneus, conditions were apparently restored to normal.

93 Intestinal Putrefaction with Different Kinds of Infant Food (Darmfäulnis im Säuglingsalter) N Söldin
94 Intubation at Munich (15 Jahre Intubation) P Reich

92 **Alimentary Intoxication.**—Finkelstein continues his study of this subject, his previous communication was summarized in THE JOURNAL, April 13, 1907, page 1306. The evidence which he presents establishes for the first time, he says, that the food—without the cooperation of bacteria—can become an active poison in the organism. He preaches that the symptoms of intoxication in the course of disturbances of nutrition are of an alimentary nature. They result from the fact that a larger quantity of certain elements of the food are ingested than the organism can dispose of. Fat and sugar are mainly responsible, while albumin can not be incriminated, and the participation of the salts is still a question. Nothing definite, he states, is known in regard to the nature of the poisons, there are objections to the assumption of acidosis. The fundamental importance of these facts for the comprehension of conditions of this kind in infants and for their treatment is beyond question, he believes. The insight thus obtained into the processes in the child will be found instructive also for many questions of general pathology. The symptom complex in the adult which we call auto-intoxication and ascribe to intestinal toxins may be due in reality to this pathologic fate of certain elements of the food in the intermediate metabolism. For the first time, he continues, the long sought evidence is forthcoming that there is such a thing as "alimentary fever." He believes that careful observation of adult patients, similar to his research on infants, will reveal many important findings. The food does not become a poison except when it is taken into an organism in which the metabolism is more or less morbid. The indispensable prerequisite for the "intoxication" is the existence of a peculiar general insufficiency of the functions connected with nutrition. This is the real trouble, while the "intoxication" is only a transient symptom. He gives a number of typical tracings and clinical histories to show the importance of the therapeutic results obtained by treatment of infants on these principles. The tracings show the influence of systematically planned changes in the diet. The "intoxication" could be made to appear, vanish and reappear at will by changing the diet, demonstrating the unmistakable connection between the food and the syndrome observed. The symptoms of intoxication appear as a regular reaction on the part of the body to certain changes in the kind and amount of the food. He deplors that lack of comprehension of these principles has resulted in injury to some of the infants in his charge in former years. Supposing, as he had been taught, that all febrile disturbances accompanied by serious general symptoms could be only the work of bacteria, and that the body required ample nourishment to support it in its struggle against the bacterial invasion, he plied the infants with even more food than usual, until convinced by the concurrent testimony of his tracings in numerous cases that the restriction of food or withdrawal of all food is the only route to safety. His experience teaches that certain febrile conditions suggesting typhoid and cholera, are solely and exclusively dependent on

alimentary influences, and can be arrested at any time by regulating the diet. The intoxication results when too much food in general or too much of certain ingredients is given, beyond what the organism can assimilate. These elements have an abnormal fate in the intermediate metabolism, and the "intoxication" is the result.

95 **Tendency to More Active Obstetric Measures.**—Hofmeier tabulates the results of prophylactic and active obstetric measures in his clinic and compares them with those of others. In 104 cases requiring prophylactic intervention, such as forceps, version or premature delivery, 26 of the children died during delivery, but all the mothers recovered. On the other hand, all but one left the maternity alive of 27 children delivered by Cesarean section, pubiotomy or symphysectomy, but 3 of the mothers died, all otherwise healthy women in the prime of life. It was found that 29 per cent of the children in this last group had died before the end of the first year. He thinks that these figures speak for themselves, and that medical students will get a confused notion of obstetrics as they see that they are taught one kind of obstetrics for their practice while an entirely different kind is practiced in the clinics. He believes on the whole that obstetric interventions might be more frequent, especially forceps operations, in the interests of the children. But the all around benefits of more extensive operations, especially the outcome for the mother, should be well studied, not merely whether a few more dozens are to be added every year to the 2,025,847 infants born annually in the German empire, especially as only 70 per cent of the dozens thus saved live to be a year old.

98 **Syphilitic Changes in Placenta, Cord and Membranes, and the Pale Spirochete.**—When Mohr commenced his research on this subject two years ago the *Spirocheta pallida* had not been discovered, but its discovery explained later many of his findings. The presence of the pale spirochete in more than 50 per cent of the umbilical cords examined and in almost 70 per cent of the afterbirths, confirms its specific importance, he thinks. The absence of nerves in the placenta shows that the spirochetes found can not be explained away as "silver stained nerve fibrils" as some have asserted in respect to other tissues. The fact that the placenta and membranes are free from external infection also excludes error from this source. Spirochetes were never found in the decidua nor intervillous spaces but they swarmed in the fetal villi and in the umbilical cord when the fetus exhibited signs of syphilis—not otherwise. He thinks that all this shows that the fetus, and not the mother is the main source of the infection in such cases. The parasites find their way into the ovum from the mother or in the spermatic fluid or pass from the mother to the fetus later. They proliferate in the fetus, acquiring new virulence, and pass then into the placental circulation.

99 **How Adhesions Form in Abdominal Cavity.**—Fromme relates extensive experiments on animals injecting blood into the abdominal cavity with or without injury of the serosa and with or without the presence of germs. The results demonstrated conclusively that blood and serum even with extensive defects in the serosa are unable to induce the formation of adhesions in the absence of germs. But as soon as the accumulation of blood becomes infected, a circumscribed infectious process results, with more or less paralysis of the abdominal intestine and subsequent development of adhesions. Accumulated blood can thus be left in the abdominal cavity without fear if it is not infected, and should be removed if it is infected.

lously removed. This should be done especially in case of ruptured tubal pregnancy. But it is unwise to try to remove all the blood which has settled at inaccessible parts of the abdominal cavity. This would spread germs throughout the cavity and, by the longer time required, would bring new germs to the spot. The trifling advantage that the body is spared the absorption of the blood would be far outweighed by the disadvantages of spreading infection to blood in remote nooks. The clots, therefore, which are not in contact with the field of operation in case of a ruptured tubal pregnancy should, he states, be left undisturbed.

100 Bladder Stone Obstructing Childbirth.—Wagner gives a skigram of the stone in his case, and describes the details of this and 46 other cases of the kind on record. Delivery was prevented by a stone in the bladder, fully 2x4x6 cm., impacted between the symphysis and the head of the child. The nature of the obstruction was not recognized until after 4 days of labor, when it proved possible to reduce the stone under chloroform. The child was then extracted, showing in eipient maceration. The patient had suffered from bladder disturbances for several months, urination at times being abruptly arrested but returning if she reclined. There were also cramp like pains in the bladder region. Eight years previously she had had about the same symptoms for a time, terminating with the expulsion of a bladder stone the size of a bean. The experiences related demonstrate the advisability of removing a bladder stone before a childbirth, as it is almost certain to cause severe injury of the wall of the bladder or vagina or of the sphincter during delivery, besides offering a mechanical obstacle to the childbirth. The operations *sub partu* show as good results on the whole as when the stone was reduced, far better than when the delivery proceeded without regard to the stone. Colpocystotomy proved most successful, especially when the bladder wall was sutured at once. This should be the routine technic if it proves impossible to reduce the stone under general anesthesia.

102 Balsam of Peru in Treatment of Wounds.—Guimarães describes a few cases of wounds treated with balsam of Peru after cleansing with boiled water. The balsam was applied for about 10 days and the results were highly satisfactory in each case. The injuries were mostly on the hand or foot and caused by machinery. In some cases the balsam was applied to a burn of the second degree, or in case of compound fracture. The urine was normal under this treatment in the cases in which it was examined for possible injurious action of the balsam on the kidneys.

104 Tropical Groin Ulceration.—Bassewitz remarks that Peruvian verruga is the most perfect type known of an affection limited to a certain geographical region, within the degrees of 75 and 81 longitude, and 8 and 16 latitude. It reigns in a limited number of valleys at an altitude of from 1,500 to 6,000 feet above the sea. The prevalence of a groin ulceration in his part of Brazil led to the suspicion that the affection might be an attenuated form of Peruvian verruga imported from Peru, but the evidence is against this. He regards the affection in question as "granuloma telangiectodes." Unna examined some specimens of the lesions sent to him and says that they suggest a circumscribed angiofibroma of the skin. The epidemic and autoinoculable character of the groin ulceration suggests a possible venereal origin, and the description was first published with the title "Granuloma Veneris."

Address

THE COMMERCIAL DOMINATION OF THERAPEUTICS AND THE MOVEMENT FOR REFORM *

GEORGE H. SIMMONS, M.D.
CHICAGO

PROPRIETARY MEDICINE A RECENT DEVELOPMENT

The proprietary medicine business as we know it is a development of only a little over a generation. In 1875, Lawrence, of *Medical Brief* fame (?), and his junta of nostrum makers, whose output and that of their offshoots alone have run into the hundreds, were unknown. Thirty years ago the so-called German synthetic chemicals were unheard of as medicines, now, if we include the true and the false, there are thousands of them. Including the typical nostrums, the more or less legitimate proprietary mixtures and the synthetic compounds, the number of proprietary medicines has become so vast that no one is rash enough to attempt to estimate it. A few of these, we may admit, have a distinct value, they represent original work and are worthy of recognition as remedial agents. The vast majority, however, are but the simplest of mixtures or are well-known drugs put out under fanciful names, with no advantage whatever, or are absolute frauds and swindles. Some of these remedies are made by manufacturing pharmaceutical and chemical houses of greater or less repute, the majority by men—or "companies"—who know nothing about medicine, pharmacy or chemistry, and who have gone into the business as they might have gone into any other get-rich-quick enterprise.

This business has been growing more rapidly than ever during recent years, and the statement made here in Baltimore last December that the use of this class of preparations has doubled during the last decade is probably true. But worse than the increase in number is the development in the advertising literature of unblushing falsehood and palpable deception. Conditions in this regard had become so disgraceful—I put this in the past tense because there has been a change since the Council began its work—that there seemed to be no statement too silly, no claim too extravagant, and no falsehood too brazen for use by those who wrote the advertising literature that physicians were asked to read and to believe. It was therefore not only the character of the preparations, but the methods of exploitation that had become unbearable and a disgrace to the profession that tolerated it. In brief this business, the annual profits of which run into the millions, has grown until the use of proprietary medicines by many physicians has almost displaced the use of the

individual official drug. It has checked advance in scientific methods of treatment, inhibited intelligent clinical observation and developed an optimism that is unwarranted by facts—an optimism that is more fatal than the most radical therapeutic nihilism. But above and worse than all, this commercialized materia medica has blighted our literature by debauching our medical journals and even by tainting our text-books.

And whose is the fault? That the business has developed in this country to such extent with scarcely a protest on the part of our profession, is a reflection on the common sense and intelligence of the physicians of the United States. We as well as manufacturers, are at fault. We must assume the blame for becoming such easy dupes to their enterprise and sagacity.

But a change is taking place, a halt has been called, and our profession is awakening to the disgrace of it all. It is about the movement for ridding our profession of this disgrace that I want to speak to-night.

NO PROTECTION IN THE PAST

We have long suffered from a want of governmental or other supervision over the manufacture of medicines. In no other country has the standard and quality of drugs been left entirely to the manufacturers' honor. From time to time the medical profession has made spasmodic, but weak efforts to remedy the condition, we find records of this even as early as the beginning of the nineteenth century.

The agitation of those early days resulted in the adoption of a Pharmacopoeia, the first issue of which was published in 1820. This standard by the way, was the work of physicians and was gotten out by them for the guidance of pharmacists who, however, had nothing to do with its preparation. It is to be regretted that conditions have changed and that while the physicians then were the ones interested for the last fifty years they have left it practically to the pharmacists. While the Pharmacopoeia furnishes standards which were accepted by a few as authoritative it was after all but an advisory instrument and was followed or ignored as suited the manufacturer.

The Pharmacopoeia only partially improved matters and society transactions continued to contain records of criticisms of the prevailing conditions. So it went on until the organization of the American Medical Association. At its first meeting resolutions were adopted indicating that the question was still a vital one. So again in 1849, 1850 and every year or two thereafter this subject was discussed. Then, however, the unreliability of drugs was the source of irritation, the proprietary medicine abuse not yet being so much in evidence. In 1879 we first find the Association recognizing that a great evil was being developed into a plague. In the

*The Annual Oration before the Medical and Chirurgical Faculty of Maryland, April 24, 1907.

WHEREAS Of late years many drugs and combinations of drugs bearing copyright names have been placed on the market and especially introduced to the notice of physicians and

WHEREAS Such drugs and combinations of drugs having copyrighted names are advocated in the medical journals of the country, be it

Resolved That the use of articles thus protected by copyright and the promoting of their use by advertising them in medical journals is a distinct violation of Section 4, Article 1 of that portion of the Code of Ethics treating on the duties of physicians to each other and to the profession at large and also of Section 4, Article 1, of that portion of the Code of Ethics treating on the duties of the profession to the public and of the obligations of the public to the profession. (Transactions, vol xxx, 1870, p 45)

From this time on scarcely a year passed that the Association did not take action regarding the proprietary-medicine problem, and finally when THE JOURNAL took the place of the annual Transactions it became on account of the advertisements, a very practical question. It is worth recording here that there was a time when our profession opposed proprietaryship in medicines, recently, however, this seems to be accepted as a necessary evil.

IMPOSSIBLE TO DEFINE AN "ETHICAL" PROPRIETARY

It is unnecessary to give in detail the difficulties connected with this question, or to explain how absolutely impossible it has been to decide what is and what is not an ethical¹ proprietary preparation. It certainly has been a trying question for those editors who have honestly striven to have their advertising pages clean and free from fraud. But long ago it was realized that the problem is one that the physician can not solve by himself. A physician is not supposed to be an authority on pharmacy and chemistry, he is expected to know the physiologic and therapeutic actions of drugs, but not the details of their chemical action or the intricacies of their compounding. This requires a special training and a technical knowledge entirely different from that required for prescribing for the sick.

The pharmaceutical profession bears the same relation to the medical profession that the ordnance department does to the army in the field. The fighting force is not expected to know how to make a rifle, or to have a practical understanding of the manufacture of powder and shot. The men on the firing line know how to use, but not how to make the ammunition. But nevertheless the efficiency of the men at the front is largely dependent on the integrity and honesty of the supplies of the ordnance department.

The trouble has been that the sister professions of medicine and pharmacy have not been cooperating, rather they have been drifting apart.

It was in recognition of this principle that, in 1900, there was published in THE JOURNAL a series of articles, written by a pharmacist well qualified for the purpose, on "The Relation of Pharmacy to the Medical Profession." Their object was to enlighten the profession regarding the conditions with the purpose of leading up to the suggestion of a remedy. As may be remembered, the remedy suggested was the creation of a body of pharmacists, chemists and pharmacologists who should act for the profession and examine the products on the market, or at least take up the subject from a practical standpoint. These articles appeared just before the first Atlantic City session and some of us had a vague idea of proposing such a board to the general meeting but the psychologic moment did not seem to have arrived and the matter for the time being was dropped.

And so time went on the subject receiving more or less attention in the Section on Pharmacology and

Therapeutics at each annual session, till at the Atlantic city session, in 1904, the delegates from Michigan presented to the House of Delegates a preamble and resolutions that had been adopted by their state society, which read as follows:

WHEREAS, An exact knowledge of the composition and properties of substances used in the management of disease is essential to a physician's best success

WHEREAS, Commercial push by advertisement and drummers, persuades many physicians (often the very elect), to use and commend drugs, mineral waters, artificial foods, etc., etc., of unknown composition and effects

WHEREAS As it is impossible for the individual physician to verify the statements of sales agents, to separate fact from fancy he often uses substances quite unlike those indicated, to the discredit of himself and his art

WHEREAS, The American Medical Association was organized to promote the exact knowledge and intelligent practice of its members

Resolved, That the Board of Trustees, American Medical Association is hereby requested to provide for the analysis of medicinal substances of unknown composition and undetermined effects, and to publish promptly the results in the Association JOURNAL

Resolved That the Board of Trustees be requested to appoint a JOURNAL Clearing House Commission three in number to serve without salary, with authority to have analyses made in reliable laboratories by experts of recognized ability, or to equip a suitable laboratory and employ one or more competent experts, at a yearly expense not to exceed five thousand dollars

THE COUNCIL CREATED

While these resolutions were not finally acted on, some of us realized that the time had at last arrived for something to be done, and for materializing the idea of a board of control. During the next eight months the general plan was discussed with many physicians and with such chemists and pharmacists as Professors Long, Stieglitz, Puckner, Hallberg and others of Chicago, Professor Cushny of Ann Arbor (now of London), Professor Abel of Johns Hopkins, Dr. Wiley and some of his staff at Washington, Professor Remington, Professor Sadtler, Mr. Wilbert of Philadelphia, Dr. Sollmann of Cleveland, and others. Several meetings were held, at which a few gathered and the general plan and scope of the work was outlined and discussed in all its phases. The matter was presented in detail to the Board of Trustees at its meeting in February, 1905. After discussing the matter fully the trustees authorized the creation of the board, and specified that it be known as the Council on Pharmacy and Chemistry.

Thus it is that the profession now has at its service a group of men who, for this work, possess special training and technical knowledge. Their energies are devoted to the thankless task of winnowing from the chaff of dishonesty the occasional grain of honesty.

The first meeting of the Council was held in Pittsburgh, Feb 11, 1905. This meeting was an interesting one. To me it was not only interesting, but profitable, for my eyes were opened to conditions the very existence of which I had not before realized. Among those present were practical pharmacists, practical chemists, well-trained pharmacologists and physicians. Each group saw things from its own viewpoint, compared notes and exchanged views. As I say, the result was interesting and the revelations both instructive and—humiliating.

The work to be accomplished at this meeting was to lay down certain fundamental principles that should govern the Council in its labors, to devise methods of procedure, etc. The most serious and important phase of the work was the adoption of the rules or principles which should govern the Council in deciding whether or not a preparation should be accepted.

The first thing an intelligent physician does when he is called to treat a patient is to make a diagnosis of the disease, learn its cause, and remove it if possible. On this principle the Council attacked the problem.

¹ I am well aware that we should not apply the word "ethical" to an inanimate object. I use it because it seems to be necessary.

RULE 4—INDIRECT ADVERTISING TO THE PUBLIC

It was recognized at the outset that the first objection to proprietary medicines is that the prescribing of such preparations is apt to lead to self-medication by the public and the manifest evils which this entails. The fact that physicians themselves are responsible for at least some of the "patent medicine" business is well known to every pharmacist and to every physician who has given the matter thought. A physician writes a prescription for a proprietary preparation that has a catchy, easily remembered name, and thinks that the matter ends there, but the manufacturer knows better, the patient gets the medicine, and with it all kinds of information regarding its virtues. The physician may instruct that the label, circulars, etc., be removed, but in many cases this is not done, and usually no such instruction is given. The patient learns from the printed matter that that particular medicine is good not only for the disease for which the doctor prescribed it, but for every other real or imaginary ailment with which he may be afflicted. In this way there has been introduced to the public a host of "patent medicines" without a cent of cost for advertising, except that to physicians.

The full directions for use which accompany these medicines are, in part at least, responsible for counter-prescribing by druggists. There is a peculiar fascination—at least to the average pharmaceutical tyro—in posing as a prescriber, exemplifying the old saying "A little knowledge is a dangerous thing." The "proprietary" nostrum vendors give him the "little knowledge," sufficient, that is, to sell their preparations. He soon becomes familiar with the reading matter and he is impressed, or pretends to be, with the wonderful properties of the preparation as described in the circulars. He adds his recommendation to those of the doctors whose testimonials he shows to the customers on the other side of the counter.

This indirect advertising to the public was the first evil to be overcome, and the first principle adopted by the Council is incorporated in what is now known as Rule 4. It is as follows:

No article will be admitted whose label, package or circular accompanying the package contains the names of diseases in the treatment of which the article is indicated. The therapeutic indications, properties and doses may be stated. (This rule does not apply to literature distributed solely to physicians, to advertising in medical journals, or to vaccines and antitoxins.)

It is this rule that has met with opposition from those who are not satisfied with the doctors' patronage but want that of the public also. It is this rule that is of most importance to the physician, for its enforcement will check one of the worst evils connected with the proprietary medicine business—that which makes the doctor an advertising medium to the public.

Certain manufacturers oppose it because, they say, the doctor needs the information and the instruction that is given on the labels and in the circulars. The reply is that it is not necessary for the doctor to go to the drug store to learn what a remedy is good for, even though he is one of those who depend on the manufacturer for his knowledge. If a doctor dispenses his own medicine and has to depend on the manufacturer for information regarding its use let that information be given in the literature not attached to the package.

Medicines manufactured solely for physicians' use such as the official preparations and those of the National Formulary, are not accompanied with circulars or advertising matter and there is no valid reason why

proprietary medicines should be. If the manufacturer wants to enlighten the doctor regarding the value of his preparation, let him advertise in the medical journals, let him send the circulars, or his detail man, to the doctor direct, in any event, there are many ways of letting the doctor know in what diseases the medicine is indicated without putting it on the bottle. It will be noticed that Rule 4 permits therapeutic properties and doses to be given in the literature accompanying the package. Many believe, and with good reason, I think, that the Council has been too liberal in this, that no such information is necessary in that connection.

It has become a recognized fact in the "patent-medicine" field that the easiest and cheapest way of reaching the public is by advertising through the doctor. Let me quote a paragraph that appeared in *Printers' Ink*, an advertising journal, some two or three years ago. The words are those of a "patent medicine man and, of course, were not directed to physicians:

But the patent medicine of the future is the one that will be advertised only to doctors. Some of the most profitable remedies of the present time are of this class. They are called proprietary remedies. The general public never hears of them through the daily press. All their publicity is secured through the medical press, by means of the manufacturer's literature, sometimes gotten out in the shape of a medical journal and through samples to doctors. For one physician capable of prescribing the precise medicinal agents needed by each individual patient there are at least five who prescribe these proprietaries. They are the chief standby of the country practitioner.

Three-fourths of all the prescriptions received are for these proprietary remedies, and the pharmacist simply opens the package and writes a label, "A teaspoonful three times a day before meals." The original bottle is given to the patient. He sees that the remedy does him good and when he feels a trifle run down again he goes to a drug store and buys another bottle, not troubling the doctor. He meets a friend on the street who is not looking well. "I know exactly how you feel," he says. "Now, just go and buy a bottle of ———. Best thing in the world. My doctor prescribed it for me so it isn't a patent medicine." In this way the name of the remedies advertised only to physicians get abroad to the general public.

The proprietary medicine of the future, though, will be advertised through these channels. The medical papers will reap the harvest, and the physician himself, always so loud in the denunciation of "patent medicines" will be the most important medium of advertising at the command of the proprietary manufacturer. In fact, he is that to day.

Have you ever seen an arraignment of this evil by its enemies which equals this cynical statement of its friends?

Is it necessary to say more on this point? In fact, can anything more be said? What I have just quoted should be read by every nostrum-prescribing doctor in the country, and having read it, he should go to some quiet corner and kneel down and pray the Lord to give him a little common sense.

Now, while I am quoting let me quote something else. This is from a book written by Mr. George P. Rowell, entitled "Forty Years an Advertising Agent." Mr. Rowell, as some of you may know, dabbled somewhat in the "patent medicine" business himself. He is the one who created Ripins Tabules. In this book by the way, he tells how he came to put this preparation on the market. In the chapter from which I shall quote he described the "patent medicine business in an interesting way, and tells of the fortunes that have been made and also lost. He has this to say about an 'evil' proprietary that some of you have heard of:

We had a successful ad- if ho
a medicine known as Fell h v

good that some shrewd business men in the medicine trade, who knew about it, bought the trade mark, incorporated a company with a capital of \$100,000, retained the original owner as manager stopped all advertising except in medical journals, and thereafter pushed the sale only through the medical profession. I had information at one time of a young man who was heir to an uncle, recently deceased, and had come into possession of a certificate of stock of this company, of the face value of \$8,000, and made up his mind that, shrewd as the old gentleman was, he had, without doubt, acquired trash in this instance, and I heard further, that the young man began to think better of the doubtful asset, when one day a dividend check came, and when, at the end of the year, he realized that within the twelvemonth that \$8,000 certificate had brought him \$9,000 in dividends, he began to revise his estimate of his deceased uncle's prescience in making investments.

As a "patent medicine" it was not a success, but as an "ethical proprietary" it has been proving a gold mine. So, since that time this medicine has not been advertised except to doctors through medical journals, has it? Look at the wrapper around the bottle, read the label on the bottle, notice the name blown into the bottle, and then will you doubt the statement of the average druggist when he says that nine-tenths of Fellows' Hypophosphites is sold over the counter direct to the public and that the doctors are responsible? What better method of advertising? And how easy! Newspaper advertising is expensive! It is cheaper to use the doctor.

The principle incorporated in Rule 4 is one of the most important principles adopted by the Council. It threw out at once three-fourths of the proprietary medicines on the market. For is it to be supposed that the promoters of Fellows' Hypophosphites, Gray's Glycerine Tonic, Glycothymoline, Antikamnia, Antiphlogistine, Phenalgin, Santal Midy, and most of the self-styled "ethical" proprietaries would conform to Rule 4? From their standpoint the proposal is absurd.

RULE 1—NON-SECRECY

Everybody, that is, nearly everybody, agrees that a physician should know what he prescribes. Some intimate that he has no moral right to give a medicine unless he knows what he is giving. A few emphatically express the view that it should be made a criminal offense for a physician to give a patient a medicine when he does not know exactly what it contains. I must acknowledge that I am much tempted to side with the latter. In any event, after agreeing on Rule 4, the Council again went back to general principles, and adopted the following which is known as Rule 1.

No article shall be admitted unless its active medicinal ingredients and the amounts of such ingredients in a given quantity of the article be furnished for publication. The general composition of the vehicle, its alcoholic percentage, if any, and the identity of other preservatives, if present, must be furnished.

There was little discussion when this rule was under consideration. Even the verbiage was soon agreed to. It is so palpably consistent, so absolutely fair and just that one would have imagined that it would receive universal approval. But do you remember the protests of certain medical journals when the first announcement was made and these rules published? It was simply outrageous. We were told that enterprising firms which had spent money and time in getting up a fine combination should be asked to state what the combination contained. One New York medical journal even went so far as to send a circular letter to the manufacturers offering them space in its columns for an expres-

sion of their views in regard to the outrageous attempt that was about to be made to injure their business. Certainly, this attack on vested interests was scandalous, and it was a good thing that the proprietary people were so well guarded by a journal that is published in the interests of physicians.

But the proprietary gentlemen were too wise. They did not accept the offer, since nothing appeared from them. In fact, the majority of the nostrum men have said that they always have been, still are, and always will be willing to tell physicians what their preparations contain. They agree that physicians should know what they are prescribing, that it is very necessary they should know. It would be wrong, indeed, if physicians should prescribe without knowing what they are prescribing, say these gentlemen. Surely! And the more quackish the preparation and the "company" that exploits it, the more willing they are to give a formula. Mind you, I say "a" formula.

When some twelve years ago the Board of Trustees ordered that no proprietary should be advertised in THE JOURNAL, unless the advertisement was accompanied with a formula sufficiently often to let the reader know of what the preparation consisted, they imagined that they had done away with the evil—secrecy. And this has been the cry since—publish the formula and the preparation becomes ethical. It did not seem to dawn on those who were especially interested in this subject that connected with the exploitation of the proprietaries were most extravagant claims as to their therapeutic value, and that those who would make misstatements regarding the therapeutic action of their preparations would not hesitate to stretch the truth when they made statements as to the composition. The formula was the thing. If the formula was forthcoming the preparation was ethical. But it has developed that the more fakish the nostrum the more willingly was the formula furnished. So it is not strange that there were admitted to the advertising pages of THE JOURNAL such fakes as Ammonol, Phenalgin, Labordine, Campho-Phenique, Salacatin, Hagee's Cordial of Cod Liver Oil Compound and Tyree's Antiseptic Powder.

The idea that the publication of a formula will make a preparation ethical has been harped on and emphasized until many believe it. Now the fact is most of the proprietary mixtures are simple combinations of well-known drugs that any pharmacist or even an average physician could compound if the active ingredients were known. Therefore, would not the makers of such preparations be very foolish to give the correct formula even as to the active ingredients? Surely they would be, and the average nostrum maker is not a fool.

I presume it is unnecessary to say that the Council is not satisfied with "a" formula, but demands "the" formula.

RULE 6—EXTRAVAGANT THERAPEUTIC CLAIMS

The man who has something to sell naturally wants to impress the prospective buyer with all its good qualities. This is business—honorable business. Incidentally, in the business world it is expected that the seller while emphasizing all the good qualities, will tell the truth. An exception to this rule may be made to the horse-trader. He, proverbially at least, is expected to overstep the bounds of truth in his comments on the quality of his animal. But the other gentleman knows this and discounts his statements accordingly. He examines the animal, or if he thinks himself deficient in the necessary

knowledge to pass judgment on the value of a piece of horse flesh he gets the advice of a friend who has this knowledge

I admit it is rather far-fetched to compare horse-trading with a proprietary medicine business, but there does seem to be a similarity—and also a difference. The seller in both instances is given to a slight exaggeration as to what the respective articles will do in their respective spheres of action, but in one case the buyer, at least as a rule, takes it for granted that the seller is likely to stretch the truth. At least, he is healthily skeptical about the matter and does not believe all that the horse-trader says. In the other case the buyer, to borrow a simile from another department of life's activities is quite likely to swallow not only the bait, but the tackle also. Perhaps he is not so much to blame after all. It is a little difficult for honest physicians to realize that others traffic in human life.

The claims in the advertisements of "patent medicines" are so absurdly extravagant that a "patent medicine" advertisement has become synonymous with mendacity. In too many instances this also applies to advertisements of so-called "ethical proprietaries." There is no limit to the license allowed those who write the advertising matter that is to influence physicians to use the products advertised.

To repeat again there seems to be something connected with the "patent" and proprietary medicine business that demoralizes. An honest, conservative statement about the merits of a proprietary preparation is as rare as rare sweet violets in Iceland. As regards the large majority this is not to be wondered at. To tell the truth about either their composition or their therapeutic value would be to stop their sale. But there are proprietary medicines that have merit and that would be used even if the simple unvarnished truth were told about them, but the habit of exaggeration crops out in the advertising of even these.

This was one of the evils recognized and so Rule 6 was adopted, which says

No article will be admitted or retained of which the manufacturer or his agents make unwarranted, exaggerated or misleading statements as to therapeutic value.

Of course, the principle underlying this rule is so elemental that one might think that it would meet with no opposition when put into practical application. Yet its actual enforcement has caused much trouble in spite of the fact that there has been a liberal interpretation of the literature. The diversity of opinion and varied experience in the use of therapeutic agents has been recognized and the Council has admitted every reasonable claim, everything short of absolute misstatement and palpably false pretension.

OTHER RULES

The three rules above considered meet the most objectionable features of proprietaryship in medicine. Indirect advertising to the public through the physician's secrecy in composition and false therapeutic claims. The enforcement of these three rules would do away with the main evils connected with the proprietary business and incidentally would wipe out a goodly number of the products. The other seven rules while important some of them being necessary for the enforcement of the three already referred to, need but a brief reference here.

Rule 2 is

No chemical compound will be admitted unless sufficient information be furnished regarding tests for identity, purity and strength, the rational formula or the structural formula, if known.

There are many preparations on the market, both domestic and imported, that are claimed to be definite chemical compounds, but which are not. This rule guards against such, as well as against adulteration, etc. No objection has been made to this rule.

Rule 3 says

No article that is advertised to the public will be admitted, but this rule will not apply to disinfectants and food preparations except when advertised in an objectionable manner.

This rule, of course, refers to open, direct advertising to the public, in the public press, etc. It is not necessary to defend this rule, before physicians at least. It provides for conditions entirely different from that covered in Rule 4.

Rule 5 is

No article will be admitted or retained concerning which the manufacturer, or his agents, make false or misleading statements as to geographical source, raw material from which made, or method of collection or preparation.

The proviso in this rule is incorporated in the national Food and Drugs Act and needs no comment.

Rule 7 says

Labels on articles containing poisonous or 'patent' substances must show the amount of each of such ingredients in a given quantity of the product. A list of such substances will be prepared.

This rule is not really necessary since the passage of the national Food and Drugs Act covers many of the substances referred to.

Rule 8 is as follows

If the trade name of an article is not sufficiently descriptive of its chemical composition or pharmaceutical character or is, for any other reason, objectionable the Council reserves the right to include with the trade name a descriptive title in the book. Articles bearing objectionably suggestive names will be refused consideration.

The last sentence was not in the original draft. Experience showed the necessity of such a rule. I doubt if any one will think this an unwise precaution when we run across such names as Gonosan, Gonorrin, Gonoral, and Gonol, names certainly suggestive enough even to the most ignorant layman and remembered without difficulty by those who wanted to tell their fellow-sufferers what they were taking. Gentone, Vaginol, Oophorin, Virilin, Rheumasin, Bronchitin, Pneumin, etc., are others. I am not quoting fanciful names from the 'patent medicine' list, they are all advertised to physicians as scientific preparations.

Rules 9 and 10 merely require information regarding the copyrighted name and if the article is patented the number and date of the patent. They are as follows.

Rule 9

If the name of an article is registered or the label copyrighted, the date of registration and a copy of the protected label should be furnished the Council. In case of registration in foreign countries, the name under which the article is registered should be supplied.

Rule 10 states

If the article is patented—either process or product—the number and date of such patent or patents should be furnished.

These rules were adopted in a tentative way at the Pittsburg meeting. In the following September the Council met at Cleveland and to that meeting were invited representatives of the various branches of manufacturing and importing interests for consultation and suggestion. The various rules adopted and only slight modifications were made. That as objected to by the man

Rule 4, but all who took part in the discussion acknowledged that the principle underlying the rule was a just one and would work no hardship on those manufacturers who were catering to physicians only.

At the Pittsburgh meeting it was decided that when it was necessary for the manufacturer to change the labels, circulars, and other advertising matter, he should be given ample time in which to comply so that he might not experience undue expense or hardship in meeting the requirement. At the Cleveland meeting this time was extended definitely until July, 1906. Thus previous to July, 1906, the Council accepted preparations even though the labels, literature, etc., might not have been in accord with the rules, on the promise of the manufacturer to make the necessary modifications in a reasonable time. However, since July 1, 1906, the literature, labels, etc., must be correct before the preparation is accepted.

I have discussed these rules at length that you may know what they are and what they mean. Together they give what has never been given before a definition of the term, "an 'ethical' proprietary medicine." Is it satisfactory? Together they make the standard by which the Council judges proprietary medicines. Is the standard too high?

PROCEDURE

As the members of the Council are scattered, meetings, except at rare intervals, are impracticable. The method of procedure, however, is simple, communication between the members being through a bulletin prepared and sent to each member by the secretary every Thursday. In this bulletin are arranged systematically the reports, motions, comments, discussions, etc., the matter being indexed so that ready reference to all past work is at hand for each member.

The Council is divided into three definite divisions—chemistry, pharmacy and pharmacology. Articles are assigned to a subcommittee usually consisting of but one member for preliminary report. This subcommittee consults with other members, with outsiders, and, if thought advisable, makes or has made chemical analyses or physiologic examinations. If the subcommittee desires to communicate with the manufacturer, the correspondence is conducted through the secretary of the Council, the identity of the subcommittee not being divulged.

When ready the report is placed in the Bulletin, together with such correspondence or other matter that the subcommittee may think necessary for the guidance of the members in arriving at a conclusion. The report may be preliminary or final. If preliminary, suggestions and advice are asked. If final, the article is recommended for either Class A, B, C or D and reasons given for the recommendation. When the final report is made it is before the whole Council for action. If the article is put in Class A, it means acceptance, if in Class B more definite information regarding the composition is wanted, if in Class C, certain modifications in the literature are required, and, if in Class D, it means refusal of recognition.

The assignment of an article to Class A or Class D is not necessarily final. If an article which has been voted to Class A is later found to conflict with the rules the action of the Council may be reconsidered. Similarly, an article voted to Class D may again be taken up and finally accepted if it is found that it has been made to conform with the rules.

Many manufacturers, believing that the publication

of certain information in regard to their products would detract from their value, have often volunteered to furnish information for the private use of the Council. The Council, however, does not receive trade secrets, but insists that all information it receives may be published at its discretion. The Council desires information for the profession, and not for itself alone.

CHEMICAL EXAMINATION NOT ALWAYS MADE

It is needless to say that the Council does not make chemical examinations of every remedy. Such a task is manifestly impossible. If the authors of text-books on physiology, on anatomy or on practice, were to verify every statement they made, such works could not be completed in a lifetime. Instead, the authors, by virtue of their general knowledge of the subjects on which they write, select the truths as they see them. These, finally presented in the form of a text-book, are again accepted as truths by students, because they believe that the author was competent to select from the mass of literature at his command those statements which were most probably true. In the same way the Council has attempted to prove or disprove statements which seemed questionable, while it has accepted those which, from its general knowledge, were believed to be true. In this matter it is needless to say that the Council has been inclined to accept statements made by firms or persons known to be reliable and responsible, while it has been inclined to examine more closely the statements made by irresponsible parties, or by those who seemed to be inclined to exaggerate.

FORMULA NOT ALWAYS RELIABLE—EXAMPLE

At first it was supposed that the statements of all the legitimate manufacturing firms could be taken without question. This supposition, however, was not well founded, and it is here that some of us have been sadly disappointed. We supposed that it was only the pseudo-chemical concerns, those which are not in the legitimate manufacturing pharmaceutical business who were the offenders, but in this we were mistaken. Even the regular manufacturing concerns have among their specialties preparations that are as fraudulent as are any put out by the typical nostrum vendors. One old-established house for years has had on the market a surgical dusting powder, which it advertised as a definite synthetic chemical compound, the result of great scientific research. The published formula was worded to mystify, and extravagant claims were made for the product. Our chemists showed that this wonderful preparation was a mixture containing approximately 70 per cent of boric acid, 20 per cent of acetanilid with a little thymol, bismuth, cinchonin and salol. This is by no means an isolated case, but fortunately for one's faith in business integrity there are at least some firms that to physicians as scientific preparations.

COUNCIL DOES NOT RECOMMEND USE OF ARTICLES ACCEPTED

The acceptance of an article does not mean that the Council recommends it, this is emphasized by printing the following disclaimer with every publication of accepted articles.

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that so far as known it complies with the rules adopted by the Council.

At the inception of the work, it was decided to adopt an extremely liberal policy and to accept a preparation

that met the requirements, even though it might not be considered of any great therapeutic value, or as representing anything new or important from a chemical or pharmaceutical point of view. Later, when the Council obtains the fuller cooperation of the profession, a higher standard may be adopted for acceptance. In sifting the wheat from the chaff it is sometimes advisable to have a coarse enough sieve to let a little chaff go through, but later on it may be desired to have the pure wheat without any chaff, then the sieve must have a finer screen.

It is presumed that physicians will think for themselves and use their own judgment regarding the therapeutic value of the preparations accepted.

THE BOOK—NEW AND NON-OFFICIAL REMEDIES

We have been speaking of "accepting" or "approving" preparations. Accepting for what? Approving for what? Not for the advertising pages of *THE JOURNAL*, as some have seemed to imagine. It would be absurd to go to the trouble and expense for such a purpose. In a sense, the Council is compiling a book, and acceptance of an article means that it is accepted for inclusion in this book. It will be known as "New and Non-Official Remedies," and will represent the actual tangible evidence, or result, of the Council's work. It will contain a description of those proprietaries which have been approved, together with such non-proprietary drugs as have come into more general use and are not as yet in the Pharmacopeia. Is it necessary to present arguments to prove that such a book is needed? Heretofore there has been no book, in this country at least, that a physician could turn to for information regarding non-official preparations. Every day a physician in active practice who reads sees mentioned in his journals medicinal preparations about which he knows nothing. But he wants to know. Where shall he look? They are not mentioned in the Pharmacopeia, in the National Formulary nor in but few, if in any, of the standard textbooks on materia medica. Heretofore he has had only one satisfactory source of information, if it is a proprietary—the manufacturer. And the information he will receive from him will most likely be voluminous, but too partial for unquestioning acceptance. Why not make it unnecessary for such an inquirer to depend entirely on biased information?

This book will tell him what the preparation is, what is claimed for it, the dose, where it can be obtained, and whether patented or trademarked. It will give him the most favorable information consistent with truth, quoting even the claims of the manufacturer, if they are not too optimistic. But it will tell him what will not be found in the literature sent him by the manufacturer—it will inform him if it is liable to have untoward effects, etc. It will, in short, supply him with information that is uninfluenced by commercialism.

It will be supplementary to the Pharmacopeia and will contain preparations that later will become official, as for instance, the various patented products which because they are proprietaries, are not usually admissible to the Pharmacopeia. The last revision of the Pharmacopeia contained preparations that, while in general use by physicians at the time, did not appear in the former edition. In 1893, for instance, phenacetin was in general use, but it did not appear in the Pharmacopeia issued in that year. If this preparation, which is now official as acetphenetidin is a good thing to do it was then. There are a number of such preparations already accepted that will probably be in the next Pharmacopeia.

BOOK NOT LIMITED TO PROPRIETARY ARTICLES

At the beginning it was intended to include in the book only proprietary articles, but time and experience have shown the need of including more than these. New drugs are continually being added to our therapeutic armamentarium that are not in the Pharmacopeia. For instance, a little while ago phenolphthalein, long in use in laboratories, etc., as an indicator, was discovered to have purgative effects, and clinical use seems to demonstrate that it may have certain advantages over other aperients. In fact, it is already on the market under various proprietary names, as purgen, purgen konfekt, purgatol, purgotin, laxirconfekt, laxine, el zernac, etc. The Council has decided to include this in the book. Thus physicians will be able to learn what phenolphthalein is at the outset and will not be deceived for years into using it under various fanciful names and at many times its cost. But, above all, they will not be misled by the extravagant claims of commercial interests.

Hexamethylene tetramine had been known before its value as a urinary antiseptic was discovered. Then it was put on the market under various trademarked names. At the present time the Council would undoubtedly accept this for the book, with a description, and we would not be bothered with a dozen or more different names for the same article. Incidentally, I hoped a less cumbersome name would have been given the preparation than was adopted by the Committee of Revision of the Pharmacopeia. Four trade names for hexamethylenamin already have been accepted, but this is done not to encourage many names for the same thing, but to furnish information. Thus a reference to the book will disclose that Urotropin, Formin, Methaform and Uritone are different manufacturers' names for hexamethylenamin.

The permanent addition to our materia medica of really meritorious articles has been slow, extremely slow, but the elimination of those without merit has been still slower. And, what is of more importance, this elimination has been achieved at the loss not only of money, but possibly even of human lives. The indiscriminate and unscientific drug experimentation that has been carried on by physicians at the behest of commercial interests and without any knowledge except that furnished by such interests is not creditable. It is hoped that this book will check this, to some extent at least.

BOOK WILL BE AN ANNUAL

The idea is that this book will be issued as an annual, each revision to include the addition of new drugs and proprietary articles that are deemed worthy of admission; those that for good and sufficient reasons should be omitted will be left out. The descriptive matter will also be modified as may be found necessary from the developments of the year. Manufacturers are slow to call attention to untoward results. It will be the function of the revisers of this annual to incorporate both the favorable and the unfavorable.

Personally, as one who has had experience in general practice, I know that it will be of immense value. Heretofore there has been no way for the conscientious practitioner, the medical writer or the editor to differentiate the true from the false. For the first time the book "New and Non-Official Remedies" will furnish a reliable

a reprint of the articles as they appeared in THE JOURNAL and is issued for two purposes To invite criticisms and suggestions, and, what is more important, to furnish even now a book of reference for those who want to support the Council in this movement by using only such preparations as have been approved Another similar edition will be issued shortly, slightly modified, with an index and more information than appears in the first reprint, and, of course, it will include the articles that have been accepted since the first edition was printed It is probable that two or three editions of this preliminary report may be issued before the official book is published

CAN NOT PUBLISH BLACKLIST

It has been suggested that the Council print a list of the preparations that have been refused recognition, since there are many who have intimated that they would not prescribe or recognize in any way the rejected articles This is impracticable First, because the number is too large, second, because the Council hopes that some may reform or be withdrawn without necessitating a resort to extreme measures, and, third, because it might and undoubtedly would involve us in lawsuits A blacklist is not a safe thing to make public

The Council is publishing from time to time reports condemnatory of preparations, with comments, but this has to be done with great caution, every statement must be verified or injustice might be done Further, the function of the Council is to approve rather than to condemn When it does condemn and publishes its condemnation, it is for a specific purpose, that purpose being to educate physicians by presenting concrete examples of the way they are being imposed on

CHEMICAL LABORATORY

A chemical laboratory has been established in the Association building and is in charge of the secretary of the Council, Professor Puckner, and an assistant While it is not possible to do a large amount of chemical work in this laboratory, it will be of great advantage in many ways

In connection with the movement much information relating to the general subject has been gathered This has been classified, indexed and made available for the future This, in fact, is one of the important features of the work being done in the central office In the past considerable matter has been published showing the fraudulent character of products manufactured not only in this country, but in Germany and abroad generally Such matter has usually been published in drug or chemical journals and has never come to the attention of physicians—the very ones who should have been informed

The important drug and chemical journals of the world are taken for the laboratory, and the information obtained from them is most valuable It is needless to say that hereafter physicians will be informed of matters which concern them that appear in this class of journals

In connection with the laboratory is an information bureau, in one division of which advertising literature has been collected and classified This includes booklets, circulars, advertisements and write-ups in medical journals, etc., covering the last five years The exhibit is interesting and instructive for those who want to make a study of this no-trum business, and will furnish texts for future sermons in the propaganda for common sense in therapeutics

Another division directly related to the above is a card index of those who have given testimonials or furnished write-ups of proprietary preparations These cards are made up in great part from the matter on file This division also is most interesting While it contains the names of a few excellent men, the great majority are hardly known in their own locality, and yet their opinions are accepted without question by intelligent, well-educated practitioners Some seem to have a habit of giving testimonials for all kinds of things and it requires considerable space to record the references It is encouraging to note that this exhibit is not growing so fast as it was Evidently, testimonial giving is not so popular as it was previous to a year and a half or two years ago

It is well known that while the *name* of a product does not change, the *composition* of the product may, and does To be able to show this in the future, samples of many proprietaries are preserved, with date of receiving, etc

COOPERATION OF OTHERS

One favorable development is the cooperation of other workers in similar fields A number of chemists in universities, schools of pharmacy, etc., have volunteered to assist, and it is expected that in the future the aid of such men will be of great advantage in solving questions on which they are especially well qualified to pass Several state and municipal boards of health are doing good work, and exchange of information with these is now a feature This promises to develop in the future to the mutual benefit of these boards and the Council It is hoped, in time, to interest teachers in medical colleges, such help is sorely needed

The advantage to the Council of having as members Dr Wiley, chief of the Bureau of Chemistry, and Dr Kebler, chief of the Drug Laboratory, has been very great, for it has received not only their personal aid, but also material assistance from the departments with which they are connected In fact, without the aid of these laboratories some of the work done would have been impossible The profession is also under great obligations to Surgeon-General Wyman, who permitted Dr Reid Hunt to serve as a member of the Council Through Dr Hunt's connection with the Hygienic Laboratory of the Public Health and Marine-Hospital Service, and with the permission of Surgeon-General Wyman, it has been possible to refer certain intricate problems to that laboratory that otherwise would have been difficult of solution

FOREIGN COOPERATION

Another promising feature is the fact that the Council is getting in touch with workers abroad For instance, splendid work is being done in Berlin, especially in the investigation of the synthetic chemical compounds under the auspices of the German Apothecary Society This is directed by Professor Thoms of the Pharmaceutical Institute of the University of Berlin, a chemist of international standing Correspondence with Professor Thoms has been carried on for some months, and he has offered to assist the Council whenever possible At the request of the Council, the Board of Trustees of the American Medical Association has just elected him a corresponding member of the Council

Professor Cushny of the University of London has been a corresponding member since he left this country soon after the Council was organized

It is hoped very shortly to get similar foreign correspondents in Paris, Switzerland and in other countries

Such cooperation will be of great assistance in dealing with foreign products

One of the conditions which the Council has had to meet is the exploitation of foreign goods by American agents who advertise them, sometimes innocently, under claims that are not accepted abroad. In some instances products had been sold abroad under claims regarding the composition that were shown to be false. Over there the manufacturers were compelled to modify their statements, but the old claims are still being made here. The Council has already secured a modification of the literature relating to certain foreign products by calling the American agents' attention to the fact that if such modifications were not made the actual facts regarding the preparation would be published.

A large number of preparations made here are advertised as being made abroad. Further, some are made abroad for the American market that have absolutely no sale in the country in which they are made. In due time evidences of these facts will probably be given to the profession.

I have given a brief review of the conditions which led to the organization of the Council, have outlined the principles or rules by which proprietary articles are judged, and have spoken of the mode of procedure. I have not told you of the difficulties the Council has encountered, and I think this hardly necessary, for I am sure all know without being told that these difficulties have been very great.

CONDITIONS ALREADY IMPROVED

The work has been going on for a little over two years. To all appearances there are just as many nostrums on the market and the advertising pages of certain medical journals are just as well filled with this class of medicines—in fact if the truth must be told, better, and for reasons that should be evident. But in spite of this apparent evidence of prosperity, if one looks beneath the surface one will find that a change has taken place. There has been a gradual decrease in the number of write-ups of proprietaries, there is evidence that physicians are thinking, that they have developed a healthy skepticism and no longer believe all that is told them about the wonderful cure-alls they are asked to prescribe. The detail men do not have such willing and credulous listeners. There has been a remarkable falling off in the sale of "ethical" proprietaries, especially those of the typical nostrum type. This is common knowledge to those in touch with the trade. A comparison of the catalogues of some of the manufacturing houses in circulation two years ago with those of to day will reveal the fact that not a few of the "specialties" are missing. And the descriptive matter, formulas, etc. of many others are different from what they were. A part of this is explained by the national Food and Drugs Act but only a part. Many of the changes had taken place before this law was passed.

The influence of the Council in this connection has been greater than will ever be known. The knowledge that our profession is at last awake that it has a body to expose the frauds that may be imposed on physicians has aroused some of the manufacturers at least to realize that old conditions have changed. The advertising literature is scrutinized more carefully. Positive cures for incurable diseases are not so common.

'WHAT ARE YOU GOING TO DO ABOUT IT?'

This much has been accomplished and yet what does it amount to compared with what must be done

before American medicine is rid of the nostrum blight? The work has really just commenced. The exposés that have been made and the publication of facts regarding the nostrum business have made a large minority of the physicians think. But it is evident that much more must be done to arouse them to act. And this brings us to the question, "What is the profession going to do about it?"

The Council is purely an advisory body, there is no national, state, county, city or any other law that will compel the manufacturer to recognize it or to comply with its requirements. Hence, without the support of our profession its work will be of no permanent value. But this must be more than a passive support. Simply endorsing the work by words, by commendation or by that indefinable something called moral support, is well enough so far as it goes. But if definite, permanent, tangible results are to follow, the profession must act. If the profession does not act and does not back up this movement, rest assured we shall in time drop back into the old conditions, or into even worse.

HOW THE PHYSICIAN CAN HELP

This movement was inaugurated directly for the benefit of the medical profession and indirectly for the benefit of the public. There is no question as to the final success of the propaganda, but the work will be greatly facilitated if you who are interested will.

First.—If you use proprietaries, secure the list of approved preparations and, all things being equal, give those in the list preference in prescribing. This list, with a description of each article, costs but a few cents, without the description it may be had for the asking.

Second.—Write to those whose preparations you are using and ask if the articles have been submitted to the Council, if submitted and refused recognition, why? and if not submitted why not? Bear this in mind. The manufacturers will recognize the Council and ask to have their controlled products placed in the book if physicians insist that they desire this, otherwise, they will do neither.

Third.—Ask detail men who call if the preparations represented have been approved by the Council and if not tell them that until this has been done you do not care to take time to examine the product.

Fourth.—Look over the advertising pages of the medical journals you are supporting—editors and publishers have great respect for the opinion of their subscribers—and write and ask for a square deal in the advertising, as well as in the reading pages.

Will it be out of place for me to suggest here that the members of the Council have a right to ask for your support, when they are working absolutely without pay? Is it presumed that they will keep on indefinitely and submit to jeers and sneers if those whose interests they serve do not themselves do their share?

I am sure that every intelligent physician unless he has some interests on the other side believes that the movement is a good one, and deserves all the support the profession can give it. I am also sure that every one of you believe this. But—what are you going to do about it?

Let me repeat. Moral support alone will not win this battle.

THE CURE OF UNILATERAL RENAL HEMATURIA BY INJECTION OF ADRENALIN THROUGH A URETER CATHETER.

HUGH H. YOUNG, M.D.

Associate Professor of Genito Urinary Surgery Johns Hopkins University
BALTIMORE

The following case of persistent hematuria from the left kidney of sixteen months' duration, which was cured by the injection of adrenalin in the renal pelvis through a ureter catheter, seems of sufficient interest to warrant publication

It is interesting because of supposed traumatic origin, an injury having been received ten days before the hematuria began, because pain was constantly present in the side injured, but the hemorrhage came from the opposite side, because of the absence of any signs of nephritis which is held to be generally present in such cases, and because no previous publication of the use of adrenalin for such purpose has been found in the literature

Patient—R. H. D., single, aged 36, admitted Dec. 3, 1906, complaining of blood in urine.

History—His family history was negative, as was also his past history. Patient had never had gonorrhea nor syphilis. No previous urinary trouble.

Present Illness—In July, 1905, while working on a farm, the rack of a hay wagon fell over on the patient, and a large iron bolt struck him on the right side of the back "between the ribs and hip bone." He was stunned for a few minutes, but soon was able to return to his work, although there was considerable pain present in the region of the trauma. During the next week he had a good deal of pain in the right lumbar region, but he continued at his work. Ten days after the injury he noticed for the first time that the urine was quite bloody. He feels sure that there was no hematuria before this, and says that micturition was normal in every way before and after the onset of the bleeding. There was no swelling present in either side, and he felt well but for the dull pain in the right lumbar region which had persisted since the accident. There had been practically no let up in the hematuria since its beginning, although the amount of blood present had varied somewhat. During this time his general health had been excellent and his only symptom had been a slight, dull pain located in the right lumbar region, almost constantly present but never severe. The blood had always been well mixed with the urine—never any clots. Never any pain nor discomfort on the left side, nor any disturbance to micturition. The urine was continually bloody and had been so for the previous 10 months. The patient had lost weight and was much weaker than normal. He had a dull pain "in the region of the right kidney" which he said felt beneath the ribs in front and in the small of the back on the right side. Occasionally the pain radiated toward the right hip bone, but never into the bladder, groin nor testicle. There was a slight increased frequency of urination and occasionally burning pain in the urethra. His sexual powers were normal, and he had no pain during ejaculation, during defecation or during urination with the exception of the occasional burning pain in the end of the penis previously spoken of.

Examination—The patient was somewhat emaciated and rather pale. There was a slight arteriosclerosis present. The heart and lungs were negative. Neither kidney was palpable nor tender, and there was no tenderness along the course of either ureter. The patient did not complain when deep pressure was made on the region of the kidney on either side. The genitalia and rectum were negative. The urine voided in three glasses was uniformly reddish brown in color. Under the microscope only blood cells were to be seen. There were no bacteria present.

Cystoscopic Examination—A catheter was passed with ease and there was no stricture present. The bladder was large and difficult to wash clean of blood. The cystoscope showed a slight median prostatic bar with a shallow cleft on each side. The lateral lobes of the prostate were not enlarged. The bladder was normal. The trigone was a little irregular and hyperemic. The ureteral ridges and interureteral ligament were slightly hypertrophied. The right ureteral orifice was small, secreted at normal intervals and the urine emitted was apparently clear. The left ureteral orifice was larger, located in a prominent papilla and surrounded by congested blood vessels, but no distinct ulceration or inflammation was seen. It was secreting intermittently at normal intervals and the fluid coming from it was smoky in color. The patient was given urotropin (hexamethylenamin) and was requested to return for ureter catheterization. He was also sent to Dr. F. J. Baetjer for skiagraphs to be made.

On Dec. 4, 1906, Dr. Baetjer reported that skiagraphic examination of the kidneys was negative. Within the bony pelvis and along the supposed course of the right ureter were two small shadows about 5 mm in diameter, lying close together and apparently about 1 cm above the point of juncture of the ureter and bladder. They might have been phleboliths, but Dr. Baetjer was inclined to think that they were small ureteral calculi. Nothing was seen on the left side of the pelvis or along the other portions of either of the ureters.

Cystoscopic examination was again performed and bloody urine was seen coming from the left kidney and clear urine from the right.

Ureter Catheterization—On Dec. 8, 1906, both ureters were catheterized with the double Casper ureter catheter cystoscope with very little difficulty, the catheters being introduced about 4 inches on each side. The urine coming from the left side was bloody, that from the right side was clear until about 5 c.c. had been secured, after that a small amount of blood appeared in the urine. Urine came from the left side much more rapidly than from the right, the total amount collected being about four times as much during the same interval. The urinalyses were as follows:

	Combined Urine	Right Kidney	Left Kidney
Color	Dark red	Slightly tinged with blood	Dark Red
Sp Gr	1030	Amount too small	Am't too small
Sugar	None	None	None
Urea	0.16	0.19	0.19
Albumin	Considerable	Faint trace	Considerable
Microscopic	Blood corpuscles No pus or bacteria. No casts.	Few red blood cells No casts	Many red blood cells No casts.

It seemed evident from the examination that the hematuria was from the left kidney and that there were no calculi in the right ureter, as no obstruction was encountered in introducing the ureter catheter. It occurred to me that adrenalin might be useful to cause a cessation of the hemorrhage from the left kidney and I therefore decided to introduce it through the left ureteral catheter. For this purpose 2 c.c. of adrenalin was added to 8 c.c. of sterile water. With a small syringe about 3 c.c. was first injected through the catheter into the left ureter. The syringe was then removed and bloody fluid allowed to escape from the ureter catheter. When this ceased about 3 c.c. of adrenalin was again introduced. The introduction of the fluid caused pain which the patient felt in the small of the back and beneath the ribs on the left side. When some of the fluid was allowed to escape the pain became less, but after the withdrawal of the catheters, which was done after 6 c.c. of the adrenalin solution had been introduced, the pain in the region of the left kidney persisted, and after the patient was removed from the table he continued to complain of considerable pain in this region. There was no pain referred to the region of the right kidney, and in fact the patient remarked that the dull pain which had been constantly present on that side had disappeared as soon as the pain on the left side came on. The patient soon voided a considerable amount of quite bloody urine. He then lay down for a while, but after about an hour returned home.

Convalescence—During the evening following the injection a request was received to visit the patient at his home. He felt weak and complained of considerable pain in the region of the left kidney. The urine was deep red in color, no infection was present.

On Dec. 9, 1906, the patient reported that at 8 p. m. the previous evening he had a very severe attack of colicky pain in the left side, beginning in the region of the kidney and radiating downward to the bladder and end of the penis, he subsequently passed a large clot and the pain subsided. Seven hours later and again at 8 p. m. of that day similar attacks occurred, but they were much less severe and did not last so long. The patient said that during these attacks he voided urine which was perfectly clear, but when the pain passed away the urine was very bloody and contained clots. An examination of the clear urine passed while the left ureter was plugged, shows urea 0.22 per cent.

Dec. 10, 1906. Another very slight attack of pain, slight headache and fever.

Dec. 11, 1906. At 3 a. m. the patient had a slight attack of pain in the region of both kidneys lasting two hours. Urine was still bloody.

Dec. 12, 1906. The patient said the urine was now clear. Examination shows that it was slightly smoky and contained red blood cells. No bacteria were present.

Dec. 15, 1906. For three days previously the patient had had only a slight pain in the region of both kidneys and the urine had been free from blood. He had had no fever, but he felt nervous.

Dec. 18, 1906. The urine was still slightly cloudy and showed red blood cells.

Dec. 21, 1906. The urine was perfectly clear in all three glasses, it was amber in color and a centrifugized specimen showed no red blood cells nor casts. He said that there had been no blood in the urine for three days. He had a slight dull pain in the small of the back, but there was no pain in the region of either kidney, and the pain which was present in the right side up to the time of the injection of adrenalin had not been present since. He said that this was the first time in one year and four months in which the urine had been absolutely clear. He had taken no treatment except urotropin, which had been given to prevent urinary infection. This was given for a week before the ureters were catheterized, but had no effect on the hematuria.

Dec. 30, 1906. The urine was clear, but a centrifugized specimen showed a few red blood cells. He still had a slight pain in the back, but felt well and had no frequency or difficulty of urination. Neither kidney was palpable, and there was no tenderness on deep pressure over either kidney or ureter.

Jan. 2, 1907. The urine was clear in all three glasses and centrifugized specimen showed no red blood cells and no casts. The patient felt well, had only a slight pain in the back and the kidneys were not tender.

Feb. 2, 1907. The patient had been at work for some time. He said that he occasionally suffered from slight pain in the small of the back, which was increased somewhat by active exercise, but when he was quiet he was entirely free from pain. He slept well and felt perfectly well in the morning. He had gained 11 pounds since the injection of adrenalin and his general health was excellent. His urine continued to be entirely free from blood.

Second Examination—The patient appeared well and his lips were of good color. There was a slight arteriosclerosis but the pulse was regular and of good volume, 100 to the minute. Examination of the kidney was entirely negative. There was no tenderness on deep pressure either beneath the ribs or in the lumbar region with the exception of slight tenderness on the left side on deep pressure. The urine was perfectly clear, light amber in color, sp. gr. 1019 with no albumin, no sugar and the centrifugized specimen showed no casts, pus nor bacteria. He had no treatment since the injection of adrenalin with the exception of urotropin which he took 20 grains daily for three days and has taken none since.

On March 8, 1907, the patient returned for examination. He said that he had been at work daily and that there had been no return of the hematuria. Micturition had been entirely

normal. Work seemed to produce a slight pain in the back, and several times he had a dull pain in the right side of the back, and occasionally in the left side of the back. This was present only in the daytime and disappeared in the evening. He still suffered from headaches but not nearly so severely as before. His eyes troubled him and he wore glasses which he thought did not suit him very well. He had gained in weight and general health and his strength was good. The patient looked well. Physical examination was entirely negative. The urine was clear and normal. There was no albumin, no casts, no blood, no evidence of nephritis.

The subject of renal hematuria without material cause has of late received considerable attention in the literature, and during the last few months important articles by Casper, Fowler and Chute have appeared.

Casper¹ reports seven cases of unilateral hematuria in five of which operation was performed. In four cases the hematuria was due to chronic parenchymatous nephritis, which in two cases did not show itself until several months after the operation, although sections from the kidney at operation showed definite evidence of the disease. In one case the hemorrhage came from carcinoma involving the pelvis of the kidney. In two other cases the kidney from which the hemorrhage occurred was removed one on account of injury to the renal vein and in the other case on account of the very weak condition of the patient. Although very careful macroscopic and microscopic examinations were made in both of these cases the source of the hemorrhage could not be made out, and with the exception of a few small fibrous points the kidney was normal.

Fowler² reports an interesting case of unilateral hematuria, in which he removed the kidney, microscopic examination of which showed a chronic diffuse nephritis. Subsequent to the operation an increasing amount of albumin and casts were found in the urine, and finally a few red blood corpuscles, thus showing distinctly that the apparently sound kidney was also diseased. Fowler has made a careful study of the literature and shows that many of the cases of supposed hematuria from sound kidneys were really cases of nephritis, but he quotes Schede as saying that he has found six cases recorded by competent observers in which careful microscopic studies of the extirpated kidneys showed no evidence of nephritis or other cause for the hemorrhage. I am able to add another case of unilateral hematuria without demonstrable lesion in the kidney. In this case the hematuria of several years' duration came from the left kidney. An exploratory operation was performed and during this the ureter was accidentally torn so that nephrectomy had to be done. Very careful examination of the kidney was made in the pathological laboratory of the Johns Hopkins University and nothing abnormal was to be made out. The patient has since remained entirely well. Adding the two cases of Casper we then have at least nine cases of unilateral hematuria in which careful examination showed no evidence of nephritis or other cause for the bleeding. It therefore seems evident that there are a definite number of cases in which there is no pathological explanation for the hematuria.

As regards the character of nephritis as associated with hematuria there is much divergence of opinion. For example, Pousson, Edebohl, Rossing and others hold that nephritis may at times be unilateral and in fact may involve isolated portions of one kidney. For example, chronic nephritis as associated with hematuria may be divided into two groups: first, the one in which the nephritis is diffuse and

1. *Archiv f. Klin. Chir.* Berlin, ix.
2. *Studies in Urological Surgery*,
port. xiii.

ond, those in which the nephritis is circumscribed or partial, and notes cases of Albarran and Nicolich in which careful pathologic examinations demonstrated lesions of this nature in two cases of unilateral hematuria. Casper, on the other hand, vigorously combats this view and holds that chronic nephritis is always double and diffuse and claims that these isolated lesions which have been described in kidneys extirpated for unilateral hematuria are frequently seen at autopsy where no hematuria had been present and are simply the results of some old lesion which had long since been cured. Similar lesions are frequently seen in various organs of the body. Casper says that he has catheterized both ureters in more than 100 cases of nephritis and has always found the albumin bilateral. He says that the urine in these cases never contains bacteria and that the nephritis is the result of toxic processes, and therefore necessarily bilateral. The unilateral nephritic lesions which have been described, he thinks, are the results of localized arteriosclerosis or focal bacterial infections and that their tendency is toward the formation of a localized area of sclerosis and is not progressive as in cases of true nephritis. Malherbe and Legueu, after an exhaustive study of the subject, assert that it is well established that chronic nephritis can establish itself in only one kidney and be characterized by a single symptom—hematuria. This is proven by numerous nephrectomies where nephritis was found and the patient has remained cured. A careful review of the literature shows that there is need of much work, both clinical and pathologic, in order to clear up this important field of renal pathology and therapeutics.

The diagnosis of the cause of unilateral renal hematuria is not always easy. Fortunately, the more common etiologic factors, calculus and tuberculosis, are usually recognized easily by means of the Roentgen ray and bacteriologic study of the urine. In the case of a tumor the diagnosis is not so easy. As a rule, however, the neoplasm reaches palpable size before the hematuria becomes marked, but in some instances this is not the case. Occasionally the Roentgen ray will show a definite enlargement of the kidney, and tumor may be suspected, although it is not palpable. In cases of hematuria associated with nephritis there may be many unmistakable signs of the disease present, but according to Albarran and Hamonic the hematuria may precede the disease by several years. As a rule, however, bilateral catheterization of the ureters will demonstrate albumin and casts in the urine from the kidney which is not bleeding. Casper says that cryoscopy is of little help in these cases and that the elimination of the sugar after phloridzin injections is about the same from both kidneys. In only one of four cases did Casper find the urine, obtained by ureter catheterization from the non-bleeding kidney, to be free from albumin or casts, and as the kidney was not removed in this case it is impossible to say that the albumin which has persisted does not come from the kidney operated on and that he had a definite case of unilateral nephritis. In both of Casper's cases in which the extirpated kidney was found to be free from nephritis the urine obtained by catheter from the non-bleeding side showed no casts and practically no albumin. The same was true in my case. It seems, therefore, to be pretty definitely shown that simultaneous bilateral ureter catheterization will generally show evidence of nephritis in the non-bleeding kidney if such disease is present and that in cases where the urine thus obtained is entirely normal the diagnosis of bilateral nephritis at least, can be excluded.

PROGNOSIS

This study of the literature has shown conclusively that great importance should be given to apparently causeless hematuria and that it should not be allowed to run on indefinitely without due efforts being made to determine the etiology. For this purpose bilateral ureter catheterization should always be done. The double ureter catheterization cystoscope of Casper has proved the most effective instrument for the purpose in my hands, but the new Nitze instrument is perhaps easier to manipulate. The operation can be done under local cocaine anesthesia (4 per cent cocaine in bladder and urethra), generally with little pain and without much difficulty.

Enough urine should be collected for a careful urinalysis, and a comparison between the separate specimens and the combined urine voided immediately before catheterization made. The case reported at the beginning of this paper demonstrates to my mind the importance of attempting to stop the hemorrhage by the injection of adrenalin through the ureteral catheter. The excellent result which was obtained in this case proves conclusively its therapeutic value in certain cases, and I am convinced that it is practically free from danger. Even in cases where a definite lesion, such as nephritis or renal tumor, may be present the use of adrenalin would not seem to be contraindicated, in fact, it may prove of great diagnostic value. It would seem probable that, in cases of nephritis, if the hematuria ceased after the use of adrenalin, a better opportunity would be afforded for carefully examining the urine and determining the presence of a nephritis, and it is possible that the hemorrhage with its marked weakening effects might completely disappear, even though the nephritis persisted. In the case of renal tumor I do not believe its use would be contraindicated, because I am firmly convinced that if the hemorrhage were due to ulceration of the new growth into the urinary passages it would promptly recur, so that the use of the adrenalin would not greatly delay an exploratory operation to determine the exact nature of the lesion. On the other hand, if a neoplasm were suspected the subsequent ureteral catheterization when the urine is free from blood would give a far better opportunity to study the relative value of the urine from the two sides and by functional diagnosis aid in the recognition of marked renal impairment on the bleeding side, a finding which would be suggestive of tumor.

As remarked above, however, the question of renal hematuria without other symptoms is a subject about which comparatively little is known and should receive considerable study in the future. With the use of adrenalin to stop hemorrhage we may have a measure of considerable diagnostic and therapeutic value. If we can in this way cure, as in the case reported above, cases of persistent hematuria without definite renal disease much will be gained and patients saved from the ordeal of cutting operations. If only a temporary cessation of the hematuria can be procured in other cases a chance will be afforded for a more careful study of the urine and a comparison of the function of the kidneys which may make renal diagnosis much more easy.

The Urine in Nephritis—W. G. Vincent (*New York Med Jour*) states that the further we get away from the strictly parenchymatous types of nephritis the less we can depend on the urine examinations alone to determine the actual pathologic condition of the kidney, though they give us an approximate measure of its functional value.

STRANGULATED HERNIA *

DAVID C. HILTON, A.M., M.D.
LINCOLN, NEB.

Clinically, the term strangulated hernia refers to strangulated abdominal types. It may be defined as "that condition in which the contents of the sac are so constricted or girt about that there follows pain, obstruction, vomiting, irreducibility and absence of expansive impulse."¹ The relative frequency of strangulation, based on a report of 529 cases is as follows:

- 250 cases of strangulated femoral hernia
- 250 cases of strangulated inguinal hernia
- 29 cases of all other abdominal types

The pathology of strangulation may be considered with reference to the gross anatomy of hernia, the histopathology of the strangulated parts, and the mechanisms precipitating the crisis.

By reference to the gross anatomy it is observed that the constriction may occur in the canal transmitting the hernia, in the hernial sac or its contents (Figs 1 to 7). If in the canal, it is usually at one of the natural openings or rings guarding the entrance and exit (Fig. 2). Otherwise, it may be determined by cicatricial contraction or by the pressure of a neoplastic or inflammatory swelling (Figs 3 and 4). If in the hernial sac, it may be at one or more places in the neck or fundus, or in a diverticulum (Figs 4 and 5). In such cases the sac is usually thickened by hyperplasia, or by plicature of its lining. If in the hernial contents, it is secondary to adhesions or the direct result of volvulus (Fig. 6). Constriction may also occur at a rent in the sac through which the hernial contents have extruded (Fig. 5).

The histopathology of the strangulated parts is essentially that of the phenomena accompanying passive congestion, septic infection, and moist gangrene.

Our present knowledge of the mechanisms precipitating strangulation is hypothetical. The two essential elements in strangulation are the constriction itself and the hernial contents bound off by it. The first is usually a constant; the second is a variant, in that it is subject to rapid alterations in anatomic make up, form, volume and position. In connection with the forces exciting these critical alterations, it may produce strangulation in the following ways: 1, By passing through the constriction under sufficient pressure to induce strangulation at once; 2, by undergoing critical alterations, after having safely passed the constriction that increase the pressure to the point of strangulation; 3, by the passage of an additional structure through a constriction filled with all the hernial contents it can safely transmit; 4, by volvulus in a part or all the hernial contents. The constriction itself, which is practically a constant, may become a variant by cicatricial thickening, acute swelling or external pressure. Thus it may close too tightly about the contents of an unreduced hernia and bring on strangulation.

SIGNS AND SYMPTOMS OF STRANGULATION

The earlier symptoms and signs of strangulation are abdominal pain, vomiting, quickened pulse and sometimes elevation of temperature, associated with irreducibility, absence of expansive impulse and increasing volume, turgidity and tenderness of the hernia. If the

bowel is caught we have the additional symptoms of intestinal obstruction and cessation of the gurgling sound within the hernial sac. The late symptoms are essentially those of peritonitis or of abscess formation and the more aggravated manifestations of intestinal obstruction. The pain is intermittent and colicky or continuous. At first it may be general or localized about the umbilicus or epigastrium, finally it centers at the seat of strangulation. The vomiting is at first reflex, but later is due to reversed peristalsis or the direct action of septic poisons on certain brain centers. Stercoraceous vomiting seldom begins inside of forty-eight hours. Tenderness over the tumor may develop later. A sudden cessation of pain and of symptomatic violence without reduction of the hernia is a bad omen.

DIAGNOSIS AND PROGNOSIS

The diagnosis of concealed strangulated hernia is of vital importance. Persistent abdominal pain especially if accompanied by vomiting, with the diagnosis unsettled demands a search for this condition. Strangulation of Richter's hernia, one in which only a part of the circumference of the bowel is caught, is most fatal and difficult to diagnose. In operating for this condition, it is essential not to allow the strangulated segment to slip into the abdomen without thorough examination.

Strangulated Hernia—*a* abdominal cavity, *b* hernial sac, *nc* neck and fundus, *c* hernial canal, *d* hernial contents, *w* mass exerting pressure, *x* diverticulum, *y* cicatricial contraction, *z* rent in sac.

As to prognosis, it is well to remember that the passing of each succeeding hour with strangulation unrelieved portends a decreasing chance of recovery and an increasing probability of a tedious convalescence in case of survival. In violent cases after twelve hours and in all cases after twenty-four hours, the mortality is increased by further delay at an alarming rate.

Strangulation is more common and more rapidly fatal in enterocele than in epiplocele or in entero-epiplocele. It is also more common in small and recent hernias than in large and old ones. Femoral strangulations have a larger mortality than inguinal types. To illustrate, I shall describe two cases of strangulated femoral hernia referred to me by Dr. Van der Sluis of Cheney, Neb.

CASE 1—April, 1905—Patient, a farmer's wife, of middle age, had been afflicted with a small femoral rupture for two years. At 9 o'clock one morning she noticed that her rupture had come down and could not be reduced. Dr. Van der Sluis was called and taxis tried without avail. I saw the case with the doctor at 6 p. m. We decided to prepare and operate immediately, if taxis under anesthesia would not relieve her. By 8 p. m. we were ready, having improved 100 cc. pints for sterilizers and pie pans for instrument trays. The patient was rapidly getting worse. Dr. Myers of Bennett and

*Read at the Johnson County Medical Society annual meeting, Jan. 15, 1907, Tecumseh, Neb.

1 Agnew's Surgery.

—Hancock on Strangulated Hernia.

ministered chloroform and taxis was tried for five minutes with negative results. The tissues were incised down to the hernial sac and bloody serum was encountered both outside and inside of it. A small knuckle of ileum was found badly strangulated and of a dark purple color. Hey's ligament was cut to release the constriction at the external femoral ring, and the bowel drawn out. Although the intestine had been strangulated for only twelve hours, the state of affairs within and about the sac indicated that gangrene would have set in shortly. It was decided to replace the loop within the abdomen. The femoral canal was obliterated by four interrupted sutures through the deep crural arch above, and the tissues over the ramus pubes below. The wound was closed under aseptic conditions and the patient made an uneventful recovery.

CASE 2—December, 1906. A farmer's wife, of middle age, with large irreducible femoral hernia of twenty-five years' standing, was taken sick with the usual symptoms of strangulation. At the end of twenty-four hours Dr. Van der Slice was called. At the end of thirty-six hours, consultation was held and immediate operation urged. The patient grew worse steadily. I operated toward the end of the second day without attempting taxis. The sac was large and filled with omentum and a large loop of sigmoid colon. There was some clear serum in the sac. The bowel and omentum were partially but not severely strangulated. The neck of the sac was large and the omentum firmly adherent to three-fourths of its circumference. It was necessary to cut the deep crural arch slightly to reduce the bowel. The omentum was ligated, amputated, and the stump of it sewed within the femoral canal, making as it were a new septum crurale. The wound was closed as in the preceding case. The patient has recently recovered after a complicated postoperative course.

The strangulation in the first case, a small enterocele of two years' standing, was much more complete than in the second case, a large entero-epiplocele of twenty-five years' standing. In the latter case the strangulation was precipitated by the slipping down of intestine into a sac already filled by an irreducible mass of omentum.

If omentum alone is strangulated, the case may result in recovery with an irreducible hernia. But since it is impossible to know that some part of the bowel is not included, we must treat each case with those prompt and often radical measures necessary to the saving of life in strangulation of the bowel. Unrelieved strangulation of the bowel means certain death.

As to treatment, it is best at the outset to throw a bomb shell into the midst of those who have it in hand to say what shall be done by telling them the patient will shortly die unless relieved. If they doubt you, call for intelligent counsel, and go about your task.

After the diagnosis, determine whether it is a case for taxis or not, bearing in mind the following contraindications: 1, When taxis has already been thoroughly tried, 2, when the case is extremely acute and violent, 3, when several days have intervened, 4, when dealing with an irreducible hernia, 5, when stercoraceous vomiting occurs, 6, when there is a suspicion of inflammation or gangrene, 7, when a skilful and clean operation can be immediately performed.

Taxis can not be done thoroughly without a general anesthetic. Place the patient in such a position that gravity favors reduction. If an inguinal hernia, flex the pelvis and thorax ventrad to relax the anterior abdominal wall. If a femoral hernia, the leg of the same side should be partially flexed, adducted and rotated inward to relax the fascia lata. The tumor should be drawn down in a line with the long axis of the canal transmitting the hernia. Then, while firm, continuous, even pressure is such to direct the contents of the sac in a line perpendicular to the plane of the opening through which the hernia passes, traction enough should be made on the

out the folds into which it may be thrown at the neck. The fingers of one or both hands should be so applied as to mold the part which must first pass the constriction into that form most favorable to its return. Taxis should not exceed ten minutes, for he who persists unduly will be inviting death oftener than relief. If taxis fails, immediate operation should be carried out under aseptic precautions, in order that the hernial canal, the sac and its contents may be dealt with as they severally require.

When the hernia apparently has been reduced by taxis, and symptoms of strangulation continue, one of the following conditions may be present:

- 1 Another strangulated hernia
- 2 Strangulation within the reduced contents
- 3 Paresis of the released intestine.
- 4 Reduction *en bloc* (Fig. 7)
- 5 Reduction beyond the first but not beyond the second narrow where strangulation persists
- 6 Presence of strangulation in an interstitial diverticulum of the sac
- 7 Eruption of the hernial contents through the sac into the interstitial tissues of the abdominal wall

The situation must be met by eliminating the possibility of another strangulated hernia, and operating according to indications. If it is probable that the hernial contents have not entered the abdomen, they can be exposed by an incision over the hernial tract. If they have entered the abdomen, a median laparotomy incision will, as a rule, be most serviceable.

Following actual relief of strangulation by taxis, other serious conditions may arise. Chief among these are peritonitis and hemorrhage. Such unfortunate occurrences may be due to direct injury from rough handling of the hernia, or to the fact that necrosis or active inflammation had actually set in before reduction. Again, these conditions are surgical and must be met promptly as the special case demands.

Finally, to the end of saving life in this crisis, let us bear in mind the words of Macbeth that

If it were done, when 'tis done, then 'twere well
It were done quickly

VASCULAR LESIONS OCCURRING SUBSEQUENT TO ABDOMINAL SECTION *

W. A. NEWMAN DORLAND, A. M., M. D.
Associate in Gynecology Philadelphia Polyclinic.
PHILADELPHIA

There are three bounden duties which the conscientious up-to-date surgeon feels called on to fulfill. These are, first, preservation and publication from time to time of accurate and authentic records of his work, second, the publication in the current literature of all anomalous and unusual cases, or cases of extraordinary interest, which chance to fall in his way, wherefrom the collators of the profession may eventually cull some previously unknown fact or arrive at more or less positive statistics of the rare condition, third, and morally foremost, careful reports of accidents that have occurred in his hands in order that the profession may profit by the lessening of the error. If the urine in increasing amount, parenchymatous type, the urine examination is a logical condition of the mate measure of its fi-

of the condition. In the first place there must undoubtedly supervene immediately on the ligation of the vessels, with the consequent break in the arteriovenous circle, a temporary stasis in the pelvic circulation on the side involved, with more or less distension of the veins of the corresponding pampiniform plexus. This condition may even advance to a decided varix of the broad ligament. The intravenous tension is thereby vastly increased, and any vessel, the weakest point in the circuit, may yield to the pressure.

In the second place the removal of these large pelvic tumors is followed by a decided diminution in the intra-abdominal pressure. There is produced at once an accentuation of the intravascular pressure, and this steadily increases up to a certain point as the patient rallies from the surgical shock. This necessarily contributes to the strain thrown on the broad-ligament veins, which, as has been amply demonstrated by the pathologists, suffer during the development of the tumor, more or less thinning of their walls, which in many instances are reduced to but a single layer—the intima. This thinning, which constitutes the third factor in the production of the rupture is, in reality, the primary and leading cause of the grave accident.

It will be well to note at this point that while the patient is in the Trendelenburg position the pelvic intravascular pressure is considerably lessened, so that a tendency to bleed from an obscure open vessel or from torn adhesions may not be evident until the table has been lowered. This fact was first noted publicly by Buckmaster,¹ of New York, and has since been confirmed by other operators. The obvious deduction is that the abdominal incision should not be closed until an ocular inspection of the cavity has been made after lowering the patient to the dorsal position.

It will not be inopportune to put myself on record as saying that I do not think that the blame for such a grave accident as primary hemorrhage from slipping of the ligature should be attributed so much to the material used as to the method employed in the ligation. There are distinguished surgeons throughout the country who, in all their abdominal work, employ nothing but chromicized catgut and who seldom if ever have to report a slipping or too speedy absorption of the gut. Again there are other surgeons, just as able and distinguished, who employ silk only with equally excellent results. It is not the material but the hand that uses it. The ablest surgeon may mistake the degree of tension he has exerted in tying the knot, and the trusted and most thoroughly prepared and tested gut may yield or become absorbed before the allotted time. In either case the result is the same, and the surgeon and patient both suffer.

Secondary postoperative hemorrhage is of rare occurrence and can result only from absorption of a catgut ligature, as in a case recorded by Howard Kelly,² in which the bleeding occurred on the eighth day, or from sloughing of the devitalized pedicle, as after the use of clamps or charring of the stump.

To review, from what we have seen thus far we may classify postoperative hemorrhages as primary and secondary. Primary postoperative hemorrhage may be intraperitoneal due to (1) slipping or loosening of the ligature, (2) oozing from large raw surfaces, such as are present in incompletely removed growths or from extensive adhesions to omentum and peritoneum, (3)

spontaneous rupture of the pelvic veins from increased intravascular pressure with lessened resisting power in the vessel walls, (4) subperitoneal hemorrhage from imperfect ligation of the connective tissue or peritoneum over and in front of the open mouth of a retracted vessel. The hemorrhage in the latter case, as Voiturez³ has indicated, may be limited and encysted, in which case the blood collects in the cellular tissue of the broad ligament to form a hematoma, or it may flow freely from the vagina.

In any case of bleeding if the hemorrhage has been excessive the danger ensues from the lowering of the blood tension because of the loss of fluid rather than from the diminution in the number of blood corpuscles. Hence the value of physiologic salt solution, by the use of which the lowered tension can be speedily corrected, the fluid being injected intravenously or by hypodermoclysis, or both, as in the case reported.

THROMBOSIS AND EMBOLISM.

History—I operated on Miss C, aged 28, in March, 1906, for cystic degeneration of the left ovary. The organ was considerably enlarged and sensitive, and especially painful during and after the menstrual periods. This condition had persisted for some years, and as the severity of the attacks was steadily increasing, relief was sought in extirpation of the painful gland. The operation was a simple one and unattended by any complications. There was but little visceral manipulation, although the broad ligament was tense and the appendage could be brought into the operative field only with difficulty. The convalescence was perfectly normal until the eleventh day, when some pain was complained of in the right thigh, and this soon extended down the leg. An examination revealed a slight puffiness around the ankle and some tenderness over the femoral vein. The swelling soon involved the entire limb, but at no time did it reach an extreme degree. There was an increase of from two to three inches in the circumference of the leg, but the tissues were not tense nor did the limb present the characteristic milky whiteness of the typical phlegmasia alba dolens. The temperature never reached the 100 F mark, but the pulse was considerably accelerated, ranging from 95 to 110 beats a minute. The usual course of treatment for phlegmasia was instituted, namely, absolute rest and elevation of the limb, which was wrapped in cotton, on pillows. The swelling gradually lessened and beyond the protracted stay in bed no other abnormal features marred the progress of the case.

Here was a typical though light attack of right-sided phlegmasia alba dolens occurring after a simple left salpingo-oophorectomy without complications. There had not been excessive handling of the parts, there were no clinical symptoms of septic infection, the operation had not been prolonged nor severe and hemorrhagic, and the patient was not unusually anemic or run down in general health. There had been, however, some considerable traction on the left broad ligament, and presumably on the uterus and opposite broad ligament, in order to bring the diseased appendage into view.

Krusen⁴ of Philadelphia has called attention to the scantiness of the literature on the subject of postoperative thrombosis and embolism, and he has emphasized a fact which is demonstrated by my case, namely, that in almost all the cases recorded in the literature the symptoms have developed uniformly when the patient was doing well, and often when the cure was considered complete. This is especially true of the reported cases of embolism, which, almost without exception, have developed with appalling suddenness in patients who were thoroughly convalescent.

¹ Ann. of Gyn. and Pediat., May 1894.
² Med. Record, June 8 1901.

³ Jour. d. Sci. Med. Lille, Jan. 25 1902.
⁴ Am. Jour. Obst., 1906, III 478.

The frequency of postoperative thrombosis is not great. Many surgeons fail to see a case in an experience covering many hundreds of operations. Schenck was able to gather the records of but 48 cases of thrombosis in 7,130 gynecologic operations—about 6 of 1 per cent of the cases. Dearborn⁶ holds that thrombosis and embolism are more common after operations in the pelvis than after operations on any other portion of the body. It is well known that embolism has not infrequently been noted after operations on the appendix, but what there is in pelvic and abdominal operations to favor the development of thrombosis and embolism still remains one of the unsolved mysteries of the surgical art. Dearborn suggests that in all probability some of the cases of embolism are overlooked, and that it is possible that many of the cases of pleurisy, pneumonia and pulmonary abscess, following surgical operations, are the direct result of minute embolic obstruction in the parts. Since it is well known that the commonest seat of aggravated and fatal embolism is the pulmonary region, this suggestion is very pertinent.

The causes of postoperative thrombosis have not been definitely ascertained for all cases. There are undoubtedly some factors that are positive in their etiologic relationship to the condition. Thus, there can be no doubt that some cases follow a mild degree of septic infection, due to some error in the technic of the operation. To conclude, however, that every case of phlegmasia following abdominal section is septic in origin is, in the highest degree, erroneous. The absence of fever in many of the cases—as in the one I have reported—would in and of itself indicate that it was probably a non-septic condition.

Another strongly predisposing factor in the development of thrombosis is prolongation and severity of the operation, especially when the hemorrhage has been considerable. Thus Agnew in his "Surgery" remarks that "After operation in which much blood has been lost, there is always more or less tendency to the formation of coagula. This may take place in the vessels of the extremities." In the case just reported the operation was not prolonged nor severe, nor was there the loss of a teaspoonful of blood. Therefore this second factor must be eliminated in this case. It is interesting to note in regard to this etiologic factor of an increased tendency to the formation of coagula, that recently M. Schwab⁷ has stated that a study of the coagulability of the blood in 30 patients failed to show any appreciable difference in the time required for the appearance of threads of fibrin in the hanging drop of blood in patients who afterward suffered from embolism and in the blood of those who did not. This only demonstrates the fact that our knowledge of the interesting study of coagulability of the blood as of leucoerythrocytosis and other seemingly important subjects, is still exceedingly limited.

Anemia and cachexia in association with malignancy, injury to the large venous trunks by too forcible use of retractors, ligation of a vein close to the point at which it enters the main venous trunk with extension of the clot into the larger vessel, the prolonged use of the Trendelenburg position,⁸ altered metabolism due to peritoneal exposure and manipulation, and injury of the fine sympathetic nervules—all these have been suggested as possible causes of pelvic and femoral thrombosis following abdominal section. The truth is that with the exception of the comparatively small percentage of the

cases resulting from sepsis, hemorrhage and severity of operation, we do not yet know the true etiologic history of this curious and frequently serious or fatal condition. Here is opened up a field for interesting original research work. The compilation and tabulation of all recorded postoperative cases of thrombosis might show some hitherto unrecognized fact that would do much to clear away the obscurity that at present veils this interesting surgical complication. With our present limited knowledge of the subject, many of the cases can not be ascribed to any of the possible causes that have been offered in explanation of the occurrence of the accident.

In regard to the symptomatology of thrombosis as Mahler has indicated the most important phenomenon is a persistent frequency of the pulse rate out of all proportion to the elevation of the temperature. Dearborn in his able resume of the subjects, remarks that any sudden increase in the pulse rate during convalescence from an operation, the temperature remaining about normal, should lead one to think of the possibility of the development of a thrombosis. He further adds that if there are evidences of phlebitis or thrombosis absolute rest in bed must be insisted on. Here he hits on the main element in the treatment of the condition. Absolute immobility of the affected limb, external warmth, emollient and antiphlogistic applications along the course of the thrombosed vein and thorough asepsis of the primary wound comprise about all that can be done to relieve the patient.

THE ACTION OF THE EXTRACT OF THE SUPRARENAL GLAND AND THE METHOD AND INDICATIONS FOR ITS USE

JOSEPH L. MILLER, M.D.
CHICAGO

The value of the extract of the suprarenal gland as a topical application to the mucous membranes, especially of the nose and throat is well established. Recently it has been employed extensively in a variety of different conditions, those deserving special mention being cardiac insufficiency, hemorrhage, bronchial asthma and in the treatment of various exudates and transudates in the body cavities. As it is a drug with a very decided physiologic action we should be familiar with its effect and indications for its use.

PHYSIOLOGIC ACTION

Inasmuch as adrenalin has been employed in most of the experimental and clinical work this term will be used, bearing in mind, however, that the active principle under various other trade names has the same effect.

The action of adrenalin in general simulates that of electrical excitation of the sympathetic nerves. So exact is this selective action that it is assumed that an organ contains sympathetic fibers if it contracts under the influence of adrenalin as plain muscle without sympathetic fibers is not affected. In the past it has been disputed whether this action on the sympathetic was central or peripheral. At present it is generally conceded that the action is a peripheral one affecting the neuromuscular function. The most important action of adrenalin is on the cardiovascular system, the effect produced being the same as would follow electrical excitation of the sympathetic. Three minims of the 1-1000 solution injected intracutaneously into a rabbit within thirty seconds will cause a rise in pressure of from 10 to 50 millimeters of mercury. This maximum pressure is only maintained

⁵ Ann. Crn. and Pediat. November 1904.

⁶ Münch. med. Wochschr. Novem. 1906.

⁷ Strauch. Centrbl. f. Gynak. xiii 1894.

for twenty or thirty seconds, then gradually falls, reaching normal in from two to five minutes. This return to normal is not due to disappearance of the adrenalin, but to fatigue, as it has been shown that the blood of the animal, even thirty minutes later, if injected into another rabbit, will produce the typical rise in pressure. If a rabbit receives repeated doses at short intervals the pressure effect will be less and less marked until finally scarcely any reaction occurs. However, by continuous intravenous transfusions of very dilute solutions, from 1-500 to 1-1,000,000, a moderate increase in pressure, as shown by Crile,¹ may be maintained for several hours. The increase in pressure is due chiefly to vasoconstrictor effect, partly to its direct accelerative action on the heart, very soon, however, a peripheral nervous impulse slows the heart by overpowering the accelerative influence of the adrenalin. Later when the pressure begins to fall the acceleration reappears and may continue for some time after the pressure has reached normal.

Plethysmographic tracings, during the period of high pressure, show that the output of blood at each contraction is considerably increased, indicating dilatation of the cardiac chambers, due to inability of the right ventricle to empty itself completely against the increased resistance. So great may this resistance become that the serum is forced out through the thinned ventricular wall into the pericardial sac, as first mentioned by Oliver and Schafer and which I have observed in one rabbit after a fatal dose. The venous pressure rises very slightly. In the various vessels the degree of constriction is in proportion to their sympathetic innervations. According to Schafer, the coronary vessels do not take part in this constriction on account of the absence of vasoconstrictor fibers. Brodie and Dixon² believe they have demonstrated the absence of sympathetic fibers in the lesser circulation in the lungs, as they maintain that these organs are not constricted by adrenalin. This very important point from a therapeutic standpoint has been disputed by Plummer and must be considered as still in doubt.

METHOD OF ADMINISTRATION

Large amounts may be given by mouth without any demonstrable effect on the cardiovascular system. I have administered 5 c.c. at a single dose to an adult without any subjective effect or increase in pressure that could be detected with the Stanton instrument, although taking the pressure every two minutes for the period of one hour. D'Amato³ has shown that very large doses given in this manner to rabbits do not increase pressure, although they may cause arterial degeneration. It is evident that the only indication for adrenalin by mouth would be for its local effect in hemorrhage from the esophagus or stomach. It is valueless given in this way in intestinal hemorrhage on account of the readiness with which it is decomposed in the stomach. Applied to the mucous membrane it does not usually have any constitutional effect, the action being entirely local. Bennett,⁴ however, recently reported marked cardiac disturbance with pulmonary edema after a urethral injection absorption probably taking place through an open vessel. Freely applied to the nasal mucous membrane of man or rabbit, it does not cause a rise in blood pressure. This is explained by the local vasoconstrictor

action being so great that an insufficient amount of the drug reaches the general circulation.

The results of subcutaneous injection are not uniform. The general opinion has been that when administered in this way the drug does not cause a rise in pressure. Recently in going over this work experimentally I found that in some rabbits doses of 1 c.c. were without effect, in other rabbits the same amount would cause a very marked rise in blood pressure, the curve being different from that of intravenous injections. The first effect is observed about one minute after injection, when a very gradual rise begins, the maximum of from 30 to 40 mm. is reached in from three to five minutes, gradually reaching normal in from twenty-five to thirty minutes. Meltzer⁵ has obtained these same results, but is inclined to believe that in the cases in which a rise occurs the needle has entered the muscle. I have observed a marked rise, however, when exercising special care in introducing the adrenalin, and believe that subcutaneously an increase in the general blood pressure often occurs. I have obtained similar results in man when using subcutaneous injections. In eight cases, using 1 c.c., in which careful blood pressure observations were made, seven responded with a rise in pressure of from 10 to 45 mm. of Hg, the first effect being observed in about one minute, the maximum in from three to four and one-half minutes, the maximum was maintained for from eight to eighteen minutes, the return to normal requiring from twenty-six to forty-five minutes. In one patient a nephritic with a normal pressure of 150 mm., no rise occurred.

Intramuscularly, as Meltzer has shown, there is always a decided reaction. The rise is more gradual than after the intravenous injection and much more prompt than after its subcutaneous use. The duration and action is also considerably greater than after its intravenous injection. We see, then, that a cardiovascular effect can only constantly be expected after subcutaneous intramuscular or intravenous use of this drug. When considering its application in cardiovascular conditions, the best method of administering it in any special case will be discussed.

USE IN CARDIOVASCULAR CONDITIONS

On account of its marked vasoconstrictor action the field of its greatest influence is conditions in which there is marked vasodilatation with good heart muscle. This latter should be emphasized, as the sudden increased work can only be borne by a good heart. These indications are present in chloral poisoning, shock and heart failure in chloroform or ether anesthesia. Under these circumstances there is a very low blood pressure, due largely to vasodilatation. Gottlieb⁶ has shown that when a rabbit has received increasing doses of chloral until the heart comes to a standstill the injections of suprarenal extract will start the heart beating and maintain it for from 20 to 30 minutes, and by repeated injections it may be kept beating for hours. Even when the heart had stopped beating five minutes, by injecting adrenalin and compressing the thorax he was able to start it again, and in one minute to have a blood pressure of from 50 to 60 mm. Hg. In man, when using adrenalin for this purpose, the drug should be given intravenously in from 5 to 10 minim doses, repeated as often as required, or better, continuing intravenous transfusion of normal salt solution in strength of from 1-50,000 to

1-100,000 Gottleib has shown that adrenalin is far superior to digitalis under these circumstances. Crile has demonstrated its value in surgical shock. Miles and Muhlberg caused vasomotor collapse in a rabbit by giving ether, and were able with adrenalin to cause a very prompt and marked rise in pressure, which persisted for five minutes or until the danger was past. In shock and in chloroform and ether poisoning the drug should be given intravenously. For the former, as a prolonged action is needed, continuous intravenous transfusion of a solution of from 1-50,000 to 1-100,000 is most desirable. With the latter a single injection of 10 minims of the 1-1000 solution should suffice. We have here probably the field of greatest usefulness for adrenalin. In these conditions it is a safe remedy and probably of much greater value than strychnia or digitalis.

When we consider its use in the heart failure of acute infection it is quite another problem. Here vasomotor paresis probably plays a very important rôle. We have also however, a degenerated heart muscle and it is, furthermore, not a question of maintaining the circulation for a few minutes, but for hours or even days. Under these circumstances the intravenous use of adrenalin by its vasoconstrictor, throws such an enormously increased work on a diseased heart that acute dilatation with fatal termination may follow. Gottleib has demonstrated this in a rabbit that received daily doses of diphtheria toxin until evidence of cardiovascular disturbance appeared. An injection of adrenalin then raised the pressure from 56 mm Hg to 132 mm, and maintained it there for a short time. It then sank lower and lower, a fatal termination being reached in a few minutes. Here the first result was apparently beneficial, but the heart was unable to maintain this increased work and dilatation and death followed. The same results were obtained in animals poisoned with phosphorus. If adrenalin is allowable at all in this group of cases it should be administered subcutaneously as the increase in pressure is then much more gradual.

At the recent meeting of the Association of American Physicians there was considerable discussion on its value in acute pulmonary edema. Experimentally it is well known that the usual cause of death in rabbits after an excessive dose is acute pulmonary edema. Bennett⁴ has recently reported acute pulmonary edema in man after a urethral injection of 2 cc of the 1-1000 solution. It can, therefore, scarcely be considered a safe remedy in this group of cases.

VALUE IN STOPPING HEMORRHAGE

Here I shall only consider the value of this drug in hemorrhage from vessels not accessible to local applications, as in the lung or intestinal tract. Adrenalin may check hemorrhage not only through its constrictive action but also by increasing the coagulability of the blood. The latter action can be readily demonstrated after intravenous injection. At first thought it would appear that we have here an ideal hemostatic. Its constrictor action however is more than counterbalanced by the sudden increase in pressure. In rabbits I observed that in a wound the vessels that have stopped oozing often start bleeding after an intravenous injection of adrenalin. It is also not an infrequent occurrence to have a cannula forced out of the carotid immediately following the use of an intravenous injection. In pulmonary hemorrhage there is the additional danger of possible absence of vasoconstriction and therefore the bleeding might increase by having a condition of dilated vessel

with increased pressure. Its action in stopping hemorrhage by increasing the coagulability of the blood may be more safely and effectually induced by calcium chlorid or gelatin, neither of which increases blood pressure. The use of adrenalin in controlling distant hemorrhage should be discouraged as it probably does harm as may any substance that increases blood pressure. This has led Smith, Hare,⁷ Lemover and others to advocate vasodilators in controlling distant hemorrhage.

USE IN BRONCHIAL ASTHMA

The use of adrenalin by subcutaneous injection in controlling asthmatic attacks is of recent date. Although applied to the nasal mucous membrane, it has been employed for this purpose for several years. Kaplan⁸ has reported very favorably of its action in relieving the asthmatic attack. The dosage is from 5 to 15 minims of the 1-1000 solution subcutaneously or intravenously. During the past year I have used adrenalin in eight cases of bronchial asthma with very satisfactory results. In all these cases marked relief appeared in two or three minutes and continued for three hours. Some of these cases were of long standing and the patients had employed all the ordinary remedies, but, according to their statements, none afforded such prompt and complete relief as adrenalin. From tests with other substances I am quite convinced that the results are due to the specific effect of the drug and not to any suggestive action. In none of my cases could I observe any curative effect, the attack occurred at the usual interval and with the same intensity. One patient during a period of eight months received 100 injections always with relief, no increase in the dose being necessary. In none of the cases could I observe any untoward results. J. A. Capps, however, in personal communications, reports serious cardiac disturbance in an elderly person immediately after an injection for asthma, and its use here should be restricted to patients with good heart and blood vessels. The action of this drug on asthma may throw some light on the nature of the pathologic process. It is difficult to conceive how adrenalin can relieve a bronchial spasm, one can more readily see how a hyperemia of the bronchial membrane could disappear under its vasoconstrictor action.

USE IN PLEURAL AND PERITONEAL EFFUSIONS

Barr,⁹ in 1903, after withdrawing fluid from the pleural cavity of a patient suffering from carcinoma of the lung, introduced a solution of adrenalin through the cannula and was surprised to find that the fluid did not reaccumulate. He then tried it in tuberculous pleurisy, tuberculous and malignant peritonitis and in ascites due to cirrhosis. His method was to withdraw the fluid, then introduce through the cannula 5 cc of the 1-1000 solution of adrenalin diluted to 15 cc with sterile water. After injection into the peritoneal cavity he used light massage to facilitate its distribution. Plant and Steele¹⁰ following this method, treated three cases of liver cirrhosis and two of pleurisy. Two of the patients with ascites received one treatment, the other one received two following which the accumulation of the fluid stopped. One patient later relapsed and was again relieved after one injection. The two patients with pleurisy each received one treatment and no reaccumulation occurred.

⁷ Lancet, Nov. 14, Aug. 29 and
8 N. Y. Med. News, 1907, p. 571
9 J. Urol., Feb. 1908, p. 1
10 Phila. Med. Jour., Jan. 17, 1911

These cases at the time the report was made had only been under observation a few months, too early to draw conclusions as to the permanency of the result. Barr reports untoward results in one case in which he injected 3 c.c. of a 1-1000 solution into the pericardial sac, after withdrawing 600 c.c. of fluid. The pulse disappeared at the wrist and for a short time the patient's life was in imminent danger. Plant reports colic and a rise in temperature of 2° F. after its intraperitoneal use. Exner,¹¹ and Meltzer and Auer,⁵ working with animals in order to determine the effect of adrenalin in preventing absorption and transudation in the peritoneal cavity, obtained results which lend plausibility to Barr's empirical treatment. Exner, in 1903, demonstrated that the intraperitoneal injection of adrenalin delayed absorption of poison from the peritoneal cavity. He injected into the peritoneal cavity of a rabbit 20 times the fatal dose of strychnin, preceding it by adrenalin, the tetanic convulsions being delayed fifty minutes and were much milder than in the control. Meltzer and Auer confirmed these findings. They also showed that fluorescence transfused from the blood into the peritoneum much more slowly in animals that had previously received adrenalin intravenously. It has also been demonstrated that intraperitoneal injection of adrenalin will lessen the tendency of transudation into the peritoneal cavity after excessive transfusion of normal salt solution.

DANGERS OF ADRENALIN

The special dangers attending the use of adrenalin besides those already mentioned are rupture of an artery from the sudden increase in pressure, glycosuria and arterial degeneration.

It is a remedy that must be employed with great care in all patients with suspected arterial degeneration. In elderly people, both on account of atheromatous arteries and myocardial changes, it is a dangerous remedy. Kaplan⁸ has found that glycosuria does not occur after moderate dosage. He observed on twelve patients the effect of a daily dosage of from 30 to 40 minims continued for two weeks and never detected any glycosuria. Underhill¹² has reported that repeated doses of adrenalin finally fail to produce a glycosuria in rabbits, a certain degree of tolerance being acquired. The danger from this source is very slight and may be overlooked. Much more important is the possibility of causing an arterial atheroma. In rabbits it has been found that a single intravenous injection may cause decided changes in the media and its continued use destruction of the muscle fibers and later calcification. It has, furthermore, been shown that these same changes may be produced by administration of large amounts by mouth or subcutaneously. We must not conclude, however, that its use in man with the usual dosage is necessarily attended with the same danger. We have reasons to believe that the rabbit is especially prone to such changes, as an attempt to produce these in some other animals, as dogs and monkeys, have failed. A variety of substances, some of them well-recognized therapeutic agents, as barium chloride, physostigmin, lead and digitalin, will produce these same changes in rabbits, and further experimentation would probably show that this list can be added to. It is probably true, however, that these changes are more readily brought about by adrenalin than by any other substance employed up to the present time. Again the dosage per kilo, when used subcutaneously, is fifty

times our therapeutic dose in man. When we consider that subcutaneously in animals the majority of investigators have never been unable to produce vascular changes, it would appear that the danger of the drug in this respect could easily be overestimated. Its continuous intravenous use should be discouraged. It is not probable that a single intravenous injection would cause vascular changes, although it has been shown that this may occur in rabbits, the real danger attending its use, however, is immediate cardiac disturbance, especially acute dilatation.

OCCUPATION IN THE TREATMENT OF THE INSANE *

THOMAS J. MOHER, M.D.

Medical Superintendent of Brockville Asylum for the Insane,
BROCKVILLE, ONTARIO

It will not be possible for me to consider this subject at length, but I wish to urge persistent effort in devising ways and means to find employment of a suitable kind for the insane. I do not pretend to add anything of importance to what others have said on this topic, and it is not unlikely that any one will object to my according a great deal of importance to occupation as a remedial measure for the insane, but I hope that I may be able to direct attention more strongly to the desirability of prescribing this valuable remedy in a more systematic manner.

Some authorities say that great care should be taken to assign patients to labor similar in character to that which they are accustomed to perform. Surely this is not wisdom. A patient comes from the counting house fairly saturated with the toxemia of figures. He has spent his days—and often, it may be, a considerable portion of his nights—in struggling with great and perplexing problems, as a result of which there is a failure of his physical health and a more or less complete shattering of his nervous system. To ask such a patient to perform any sedentary duties would be but adding fuel to the fire already consuming his nervous vitality.

Better far to start this patient at some occupation requiring little or no mental exertion. Send him out in the open air where he will be surrounded by conditions favorable to health, and give him a hoe, a spade, or a rake, and see that he is kept in motion. Do not attempt to explain what he is expected to accomplish. The great majority of patients will attempt to use any utensil of this kind as soon as it is placed in their hands. They appear to work automatically, little or no mental exertion being required. The power of observation appears to be aroused and developed, slowly it may be, but steadily. A simple hole is perhaps made in the soil and the patient proceeds either to enlarge this opening or fill it in or build a mound. He will continue this occupation, apparently forgetful of his delusions, for a time, but suddenly the abnormal ideas return and any attempt at occupation ceases. Here is where the properly trained attendant is able to render valuable assistance. He has, or should have, a good knowledge of the temperament of his patient and can, by tact and patience, encourage him to recommence his work. It was a revelation to me to notice the progress made by patients from day to day. At the outset perhaps a few minutes would represent the time spent in work, but this time is gradually extended until a patient may continue his occupation for an hour or longer,

¹¹ Arch. f. exper. Path. u. Pharm. 1903, p. 313.
¹² Amer. Jour. Phys., xvii, p. 42.

*Read before the British Medical Association, Toronto.

apparently unconscious of his surroundings and forgetful of his delusions. Of course, even after the patient has made progress and understands the nature of the work in which he is engaged, and why he is asked to perform it, he may become obstinate and refuse to do more. In such an event no force should be used. Allow him to remain indoors or to spend his time with the walking parties, etc., for days, if necessary, and await confidently the time when he not only consents to accompany the working parties, but expresses a desire to do so.

I might cite a number of cases to explain more fully what I desire to express, but time will not permit. This case, however, will interest you.

A young man, in the prime of life, was sent to the hospital for treatment. He was the most perfect specimen of physical development that I have ever seen. He was brought in on a mattress to which he was firmly bound. This patient had occupied a position of great financial responsibility, and filled with an energetic young man's determination to master all the details of his work he spent day after day and many a night at his desk. His domestic environments were such that he was denied rest even when he tried to obtain it, and he never thought of recreation. His general health became impaired, followed by a complete mental breakdown. After his admission he would destroy his bedding, clothing and everything he could lay his hands on. He went on all fours and fancied he was a ferocious animal in a cage, and sniffed and snapped at everyone. He continued in this way for some time with little if any improvement, although his condition varied somewhat from time to time. Spring came, however, and instead of looking for some occupation befitting his condition in life, he was provided with a spade and sent out with the working gang. He was dull and stupid and seemed to move about mechanically. He soon began, however, to use the utensils supplied him and in less than a week I was surprised and delighted when he asked me to sit with him under the shade of a tree, as he had something to say to me. For the first time since he came to the hospital, more than three months previous, he appeared to realize that something was wrong and asked for an explanation, but the mental cloud was yet too dense to make him understand. I had previously ascertained that this patient had a hobby for gardening in his spare time, and it would appear that even in his afflicted condition enough of his old inclination remained to induce him to persist in his work. He made a good recovery and subsequently resumed his former occupation.

This case has impressed me with the necessity of studying the temperament of a patient before selecting his occupation and of endeavoring to obtain as much information as possible regarding the previous history, not forgetting the whims and fancies.

I will cite one more case to point out the danger in allowing a too great time to elapse before placing a patient at work.

A male patient, aged 30 years, was admitted suffering from acute mania. He fancied he was charged with electricity and was alarmed lest he might unintentionally injure his friends. He was very irritable, attacked the other inmates and was considered a dangerous patient. He became a great nuisance on the ward and was sent out under the care of an experienced attendant, who with nine other patients, were engaged in grading. He commenced to improve at once, forgot his delusions and ceased to provoke trouble while indoors. In a short time he was discharged and has been well for almost two years. I am convinced that this patient's restoration to health could not be so completely and quickly effected in any other way.

The percentage of patients who are not likely to derive benefit from occupation of some kind is very small, indeed. If we exclude those cases who are physically unfit and those who are in the advanced stages of dementia the proportion who are unable to perform work of any kind almost disappears. A considerable number

of patients with acute mania are, during the early stages of the disease, unable to perform any labor, but this period of enforced idleness may be very much shortened if careful and systematic efforts are made to ascertain the earliest possible time when simple occupation may be attempted. Paretics, too, during the period of exaltation, are not capable of undertaking work of any kind, but it is not unusual to find them able to perform considerable work later on in the disease. Some patients who have dementia præcox also absolutely refuse to do anything, no matter how persistent our efforts may be.

Occupation should be simple at the outset. It does not require much mental effort on the part of any patient to push a heavy brush up and down the corridor on the polished floors, and this effort is much less when the patient is only one of a large number moving up and down in the form of a procession. It is little more than an exercise in walking, while it serves as a stepping stone to something more complicated. This simple occupation is continued longer than the condition of the floor requires, the principal object being to endeavor to direct our patients along the line that leads to something better. A change to outdoor exercise is made just as soon as the patient is reported as being able to perform the simpler indoor labor with very little direction from the attendant in charge. It is true that patients vary much in the time necessary to reach what I may call an "outdoor stage," but the great majority are sure to advance this far.

While I think it is unwise to restrict any class of patients to any particular work, nevertheless it is true that certain patients can not be induced to perform any work other than that to which they are accustomed. I have in my mind the case of a tailor who was exceedingly dull and sluggish, refused to eat or speak and could be only moved from place to place with difficulty. It was useless to attempt to force him to brush or to do anything else, yet when a needle and thread and a piece of cloth was placed in his hands his interest appeared to be aroused and he made some attempt to ply his trade. This led to better things, and later on he was sent to the tailor shop where he proved to be a skillful workman. Another matter that should never be forgotten is that certain classes of patients should never be asked to perform the more menial services that must always be rendered in every hospital. In matters of this kind the same judgment should be exercised in selecting certain persons to fill certain positions as is used in the world at large.

Friends of patients often object to the rule in force to induce every person who is physically able to engage in some occupation, and this objection comes from the poor as well as from the rich. It is assumed by many that the poor are asked to labor in order to defray the expenses in connection with their maintenance. Others assure us that certain patients are under no obligation to labor, as their friends are willing to pay for all they receive. It takes a little time and patience to point out to persons making these objections that occupation is a remedial measure and that it must be administered in accordance with the requirements of the patients and under the direction of those who are in charge of the asylum. The time occupied in making such explanations is well spent, however, and later on we will find that the number of persons objecting gradually diminishes. I even now the general public is so impressed with the importance of occupation that complaint is often made when visitors come and find their friends who for some reason may be in the ward, unoccupied.

Once the facts that occupation is an important remedy

in the treatment of insanity and that it must be administered in an intelligent and systematic manner, are firmly impressed on the minds of the attendants, little difficulty is found to keep patients employed. Patients who, previous to their arrival at the asylum, belonged to the indolent class and who were never obliged to perform any labor, may consider it a hardship to do so, but they are soon influenced by their surroundings and learn to fall in line and perform such duties as may be assigned to them. The fact that they are not asked or permitted to overwork themselves and that attendants are expected to make their outdoor life as cheerful as possible, robs labor of much that is disagreeable in their minds. Even persons belonging to this class are glad to be permitted to participate in the advantages to be derived from occupation.

My experience has taught me also that it is unwise to offer any pecuniary reward for services rendered by a patient. If this plan is permitted, patients are encouraged to think that they are employed for the benefit of the institution and not for their own good. It also encourages jealousy and serves to engender a general feeling of dissatisfaction and unrest that is not at all conducive to the physical or mental improvement of the patient. A full day's pay is impossible and a lesser amount is unsatisfactory. Better far to eliminate this feature altogether and to encourage the feeling that occupation is the best and most easily administered remedy known to us at the present time.

How does occupation effect a cure? This is not an easy question to answer. Delusions may be nothing more than mental expressions of physical disease. At all events we know that in a large number of cases mental improvement is coincident with the return of physical health. As a result of suitable outdoor employment, we find that patients are less restless, sleep better, their appetites are improved and the secretions become normal. The gentle perspiration helps to eliminate the excess of toxic products and the muscular exercise tends to tire the patient sufficiently to induce quiet sleep. While in the wards, too, they become less noisy, less quarrelsome, less destructive and much better behaved generally. One thing is certain, that the coated tongue, the obstinate constipation, the diminished secretions, the sallow complexion and the other symptoms of ill health that very stubbornly resist other methods of treatment gradually disappear when patients are engaged in suitable occupation and we can nearly always look forward with confidence for a marked improvement in the mental condition.

While I have no objection in stating that the cure of a large number of patients may be attributed to occupation, I am also of the opinion that the greatest good is conferred on the incurable cases by delaying dementia and by adding to the comfort, happiness and general well-being of the chronic insane.

The fact that the employment of patients materially lessens the cost of their maintenance and saves the expenditure of hundreds of dollars annually in the carrying on of the various industries in connection with an asylum for the insane is, of course, a matter of some importance. But when we attempt to consider what the restoration of a patient's health may mean to his family who may be dependent on him for support, or when we try to estimate the value of the happiness that lights up the home when a loved one returns, whose departure has enveloped his own fireside in the shadows of sorrow and desolation and left behind him the fearful dread that he may never recover when we consider all this we must

forget such matters as finance and carry on our various works with the sole object of improving the mental condition of our patients. Our annual reports contain elaborate statements in detail of the handiwork of our patients. We report from 50 to 75 per cent as having been employed and the total number of days labor is very large, indeed. I am inclined to believe that these figures are not always accurately compiled, yet they go to show that a great deal of labor is being performed by patients in the different institutions. But this in itself is not everything. We should endeavor to carry on our work in such a way that every manufactured article will represent in some measure an improvement in the mental condition of a patient, and not a single piece of work of any kind should be placed to the credit of any institution if its performance interferes in any way, with the recovery of a patient.

Much that I have said in this paper applies to amusements and entertainments which I look on as important aids to be employed in connection with occupation.

SUMMARY

1 Only a small proportion of our patients should be exempt from labor.

2 A careful study should be made of the temperament of each patient before deciding the kind of labor suitable in each case, and the previous occupation or social condition should not be the only determining factor.

3 The carrying on of this work successfully depends in a large measure on the attendants in charge. Attendants should be selected with care and carefully instructed.

4 Members of the medical staff should visit the working parties regularly for the purpose of studying individual cases.

5 Patients should never receive wages. It is possible that such a system may appear to work successfully in some cases, but in the end it is sure to create trouble.

6 In some cases it is advisable to encourage patients to learn a trade, so that they may the more easily earn their living after their discharge.

7 Agricultural pursuits and caring for grounds appear to be ideal labor for the great majority of patients.

8 Female patients may with advantage be employed in the vegetable and fruit garden, weeding, picking berries, etc., in addition to the work performed in the day rooms, dormitories and dining rooms. They should also perform fancy work, do all the mending, and assist in the industrial department in the making of mats, mattresses, etc.

TUBERCULIN TEST*

C. P. AMBLER, M.D.
ASHEVILLE, N. C.

Eight years ago, in a paper on the "Early Diagnosis of Pulmonary Tuberculosis," I made the statement that the tuberculin test had been accepted for testing cattle, but that this procedure would be slow in becoming popular with our profession as a means of confirming or rejecting our suspicions in the human being. It was compared to hunting for a gas leak with a lighted candle.

Having used tuberculin, in its various forms, since it was first brought out, I am more convinced to-day than ever that in tuberculin we have our most efficient remedy in fighting this disease.

*Read before the Buncombe County (N. C.) Medical Society, Feb. 18, 1907.

Experience has convinced me more firmly than ever that its use under proper precautions and with a full appreciation as to its limits and results is justifiable and advisable, while this is true, I am just as firmly convinced that my old comparison of "hunting the gas leak with a lighted candle" is still applicable, but with this addition, experience has shown how better to guard the light. So powerful an agent can be safely used only when the utmost caution is exercised and the indications for its use are given the consideration and attention which they demand.

Ten years ago those of our profession who advocated and used tuberculin were few and far between, during the first years of its use (as has been the history of all our greatest medical discoveries) the remedy was abused at the hands of those who employed it in half-moribund patients and in cases in which it should never have been used either as a diagnostic measure or in treatment. To-day we find a majority of the progressive members of our profession using the remedy at least as a diagnostic measure. Those who a few years ago were loudest in their denunciations have now become non-committal. Ten years more will without doubt convert those who are skeptical to-day.

A tuberculin test will frequently clear up the diagnosis in cases in which, without the remedy, the true nature of the disease would otherwise remain obscure until the disease had become more advanced and valuable time had been lost.

REACTION TO THE TEST, PROOF OF THE PRESENCE OF TUBERCULOSIS

The fact that animals and human beings will react when no evidence whatever of a tuberculous disease exists (otherwise than found by a tuberculin test) does not prove that a reaction can or does occur without the disease. It is well known that a small local tuberculosis may be present in any organ of the body without the patient or physician being aware of its existence. It has been claimed that a reaction will occasionally occur in uncomplicated syphilis. The more we become acquainted with tuberculin and its action the more certain do we become that we have been lame in our diagnosis, that our powers of discernment and judgment have been at fault, and that a reaction means tuberculosis, no matter whether we find the deposit or not.

Veterinarians have been able to satisfy themselves on this point more quickly than we have, from their ability to get a postmortem immediately following the reaction if desirable. Were it possible that we also could secure an autopsy in all cases and dissect the body as carefully and in the same detail as does the veterinarian we should undoubtedly find evidence sufficient to convince us that the occurrence of reaction to tuberculin means tuberculosis.

The majority of tuberculous foci starting in the human body probably never produce an open tuberculosis. A reaction, when such shut-in tuberculosis exists, will occasionally produce sufficient local manifestation (throat, pulmonary, articular or glandular) so that the diseased area may be determined accurately during the reaction.

Experience shows that the more recent case will give a stronger reaction to a given dose than will a case of longer standing, further, the more recent case will react to a much more minute dose than will a case more advanced.

IN WHAT CASES SHOULD THE TUBERCULIN TEST BE EMPLOYED

In pulmonary work we are constantly finding patients presenting absolutely no symptoms of tuberculosis except a hacking cough, associated with bronchial inspiration, and perhaps prolonged expiration or slight dulness on percussion, the temperature, sputum, history, weight, etc., all fail to aid us in our diagnosis. What are we to do? Wait, as we would do in syphilis, until more positive signs appear? No, it may then be too late or the patient may not return. A tuberculin test properly given under such conditions is of the utmost value to both patient and physician.

A sputum examination giving negative results in itself, unless repeatedly made, is not an indication for tuberculin. All other means of arriving at a correct diagnosis should be employed before resorting to a tuberculin test, not that I believe this test is dangerous or that it ever aggravates the disease, but the depression of the reaction fever, nausea and other concomitant symptoms are not desirable in any one, and particularly is this true in a patient suffering from tuberculosis. The claim made a few years ago by various observers that a reaction excited a latent deposit or developed a quiescent disease into an active one has not been proved by facts and experience.

In joint troubles, bone disease, persistent wasting without pulmonary symptoms, chronic pleurisy, bladder trouble, and especially in adenitis, is tuberculin most valuable as a diagnostic measure. It is rarely necessary or advisable to use the tuberculin test in cases running a daily maximum temperature of over 100 F. I have never used the test in a suspected case of brain tuberculosis.

WHAT TUBERCULIN SHOULD BE USED

After trying several makes and modifications, I have found that the tuberculin made by Koch and imported through Victor Koechl & Co., New York, is the most satisfactory and is apparently more nearly "standardized" than any other.

ADMINISTRATION

The temperature of the patient should be taken once in three or four hours for a period of several days before giving the first injection. As a rule, I have not used the test in patients having maximum temperature over 100 F. Different observers advise dosage ranging from one to six milligrams, some giving the tuberculin in slowly increasing amounts over a period of a week or more, others going to the opposite extreme both in amount used and in the number of injections.

While I would not advise the use of the maximum dose as a test measure I believe that the slowly increasing method of administration is faulty in that many individuals quickly acquire more or less tolerance and fail to react (even in the space of a week or ten days) as they would had a larger amount been given earlier.

In the average adult I use 2 mg. at the first injection, preferably giving it late in the evening, continuing the temperature record for two days, if no reaction occurs 5 mg. is then given on the third day. This plan, in my experience, avoids excessive dosage and obviates the possibility of developed tolerance. The injections are given with a graduated syringe in the subscapular region, the needle being inserted into the deep fascia but not into muscle tissue.

The tuberculin is diluted with a 0.5 per cent solution of carbolic acid and distilled, filtered and sterilized.

water, little local discomfort results, such hyperemia as follows subsiding in from twenty-four to forty-eight hours

WHAT CONSTITUTES A REACTION

A tuberculin reaction may be either local or general. If local, the symptoms may be confined to a small area and consist of congestion, swelling, pain, tenderness on pressure, or increased secretion. Local reactions, as a rule, are not clearly defined, they occur particularly in laryngitis and in disease of the joints and of the larynx, it is not infrequent that increased moisture will be heard over a suspected area in the lung without other change in the character of the respiratory sounds. In a general reaction the symptoms may be slight or so severe as to give rise to grave apprehensions on the part of the patient or the friends. The symptoms usually occur in from twelve to twenty-four hours and consist of fever, pain throughout the body (particularly the back and joints), nausea, vomiting, headache, increased cough and expectoration, restlessness, chill or the ordinary evidence of a common cold. Many of these symptoms may be entirely lacking, others existing either slightly or to a severe degree. The most distinctive evidence of reaction is usually presented in the change of temperature a variation from one to even three or four degrees from the record for the previous days being taken as a positive evidence, other possible causes, of course, being eliminated.

The reaction may be retarded, not coming on until the second day, then appearing suddenly and presenting the most conclusive evidence. Even when the reaction is violent the maximum is reached in a few hours, the symptoms then subsiding gradually, so that in twenty-four hours from the outset the patient is again practically normal. I have occasionally had my attention called by the test to the larynx, where, beforehand no suspicion of trouble existed, the reaction causing slight or marked local redness with such symptoms as occur in ordinary acute laryngitis. Slight chill, a rise of two to three degrees in temperature and more or less aching is the rule, nausea being less frequent and vomiting rarely seen.

ALL TUBERCULOUS PATIENTS WILL NOT REACT TO THE ORDINARY TEST DOSE

As has already been pointed out, a recent case, or one presenting but a small or circumscribed deposit, will react more positively than will the usual well-developed case or one in which there is extensive involvement. In other words, in the advanced or extensively involved case a certain degree of tolerance is established to tuberculin as evidence that Nature produces in the body the same resistive element (call it partial immunity, if you like) that occurs when tuberculin is used in gradually increasing dosage.

WHAT PRODUCES THE REACTION

With all that has been written, following innumerable experiments on lower animals, after the most painstaking laboratory experiments as yet there is no satisfactory explanation for the phenomena of the tuberculin test. Empirically we know the results as we do with man, remedies, scientifically we are in the dark here as we are with the "how and why" of the action of many of our simplest and commonest remedies.

In conclusion I wish to affirm my belief in the efficacy, safety and positive diagnostic value of a properly

conducted tuberculin test, and to state that while a failure to react is not proof positive that the disease does not exist, a clearly defined reaction must be accepted as diagnostic proof of the existence of tuberculosis.

Special Article

WATER SUPPLY AND PUBLIC HEALTH CHAPTER I

WATER AND DISEASE *

The causal connection between water and disease has been impressed on the human race by a series of tragic occurrences. Throughout the Middle Ages a common explanation of any sudden outbreak of epidemic disease was that "somebody had poisoned the wells," and this unhappy hypothesis often led to a destruction of life which was even greater than that caused by the original epidemic. The belief that certain outbursts of a specific disease were somehow associated with drinking water did not, however, become general until about the middle of the nineteenth century, when a number of facts hitherto seen through a glass, darkly, first came into clear view in connection with the causation of Asiatic cholera.

(a) *Asiatic Cholera*—This disease afforded an early and conspicuous demonstration of the relation between a specific disease and the use of a given water supply. The famous case of the "Broad Street Pump" in London in 1854 has long been celebrated as an epidemiologic classic.¹ It will be recalled that a remarkably concentrated and explosive outburst of cholera occurred among the persons who used the water from a certain well in Broad Street. The circumstances surrounding this outbreak were such as to foster immediately the suspicion, even in those prebacteriologic days that the well water contained the "specific poison" of Asiatic cholera. Fortunately for the advance of preventive medicine, the investigation of the occurrence fell to the lot of several shrewd and competent observers who succeeded in securing convincing evidence, amounting indeed to virtual proof, of the causal connection between the use of the water and the production of infection. It is with much reason that some writers date the beginning of modern epidemiology from the inquiry into the Broad Street pump epidemic of Asiatic cholera.

In more recent times the connection between drinking water and Asiatic cholera has been graphically shown in the famous Hamburg-Altona epidemic of 1892-3. Here similar population groups in the two cities, living under identical climatic and social conditions were most diversely affected. The residents of Hamburg were supplied with unfiltered water from the River Elbe and suffered severely while the inhabitants of Altona, who were supplied with filtered water from the same source, remained almost entirely exempt. Topographically and industrially the two communities were under identical conditions the character of the water supply alone determined the presence or absence of infection. In those districts in which the Hamburg water mains passed across the boundary line for a short distance into Altona a tongue of cholera infected houses projecting into Altona betrayed the presence of the infected water.

(b) *Typhoid Fever*—The evidence connecting epidemics of typhoid fever with drinking water is intrinsically more difficult

*[This is the first of a series of articles on the relation of water supply to the public health. Succeeding papers will treat of kindred topics such as the methods of sanitary water analysis, the methods of water purification and similar themes. Many of the existing treatises on water and water supply have been written primarily for the engineering rather than for the medical profession and it has seemed to us desirable to secure a presentation of this subject that shall be of especial value to medical readers. In most communities physicians rather than engineers constitute the membership of the local board of health and it is to the former consequently that the public must look for proper guidance in the matter of safe water supply. As a matter of fact the water supply problem is often of a hygienic rather than of an engineering character.—Ed.]

¹ Sixth Report of the River Pollution Commission, Appendix 10, p. 499. An excellent detailed review of this outbreak is given in "Principles of Sanitary Science and the Public Health" by W. T. Sedgwick. The Macmillan Co. 1902.

to secure than in the case of cholera, owing to the long period of incubation and the frequently obscure symptoms of the former disease. Nevertheless, an overwhelming number of cases is on record in which the association between the use of a particular drinking water and an outbreak of typhoid fever is so direct as to admit of no doubt as to the causal relationship.

There is no need to recapitulate here in detail the features of the more familiar water borne epidemics of typhoid fever. These are for the most part on file in easily accessible publications. Among the classic epidemics may be mentioned the one at Lausen, Switzerland, in 1872, at Plymouth, Pa., in 1885,² at Worthing, Eng., in 1893,⁴ at Ithaca, N. Y., in 1903,⁵ and at Butler, Pa., in 1903.⁶

In addition to the evidence afforded by these epidemics of a circumscribed and definite character, there is a large body of evidence, less direct to be sure but very cogent, derived from a study of the typhoid fever death rates in those cities afflicted with more or less polluted public water supplies. Attention has often been directed to the low typhoid fever rate in cities supplied with a surface water purified by sand filtration as compared with the higher death rate in cities furnished with unfiltered surface water.

TABLE 1

Cities Using Sand Filtered Surface Waters.—Typhoid Rate per 10,000	Sur	Cities Using Unfiltered Surface Waters.—Typhoid Rate per 10,000	Sur
Berlin	0.50	Boston	2.79
London	1.40	New York	1.51
Hamburg	0.90	Baltimore	4.70
Rotterdam	0.20	St. Louis	4.70

Table 2 shows the death rate from typhoid fever in the principal cities of two large states. In one of these states the public water supplies were under the direct legal control of the State Board of Health; in the other such authoritative supervision was lacking.

TABLE 2.—Average Typhoid Fever Death Rates (1898-1902 and 1900-1901)

PENNSYLVANIA		MASSACHUSETTS	
CITY	DEATH RATE	CITY	DEATH RATE
Pittsburg	108	Boston	30
Allegheny	86	New Bedford	30
Johnstown	86	Springfield	27
York	81	Lawrence	25
Chester	64	Taunton	25
Lancaster	59	Dorchester	21
Philadelphia	54	Chelsea	21
McKeesport	51	Salem	21
Reading	50	Worcester	21
Allentown	49	Lowell	21
Harrisburg	41	Lynn	21
Altoona	33	Newton	20
Wilkes-Barre	29	Cambridge	18
Erie	28	Worcester	18
Scranton	23	Mill River	15

An immediate and striking effect on the typhoid fever death rate has often been observed when a city has exchanged a polluted water supply for one of more satisfactory character. Thus the city of Vienna between 1851 and 1874 procured its public water supply from the River Danube and during this period the typhoid rate ranged from 100 to 340. In the latter year a pure spring water was introduced and the typhoid rate at once became and has since remained consistently low, averaging only 5.1 in the years 1898-1902. In Chicago the typhoid fever death rate fell to the lowest point recorded in the history of the city in the year (1900) immediately following the opening of the Chicago drainage canal which diverted a large portion of the city sewage away from Lake Michigan, the source of the city water supply.⁷

A singularly instructive condition existed at one time in the city of Paris. The main water supply was obtained then as now from various springs and small rivers and was of fairly satisfactory character but during certain seasons this source proved inadequate and the scanty supply was eked out with water from the polluted River Seine. In order that every part

of the city should share alike each improvement was supplied in turn with river water due notice being given through the public press to the residents of the district concerned. That the authorities clearly recognized the situation is shown by the fact that if the river water was supplied for more than twenty days of the year the householder had the right to demand a reduction in his water rates (Legge). The effect of the orderly distribution of the Seine water was manifested by a miniature epidemic of typhoid fever which followed the course of the Seine water from one section of the city to another. In 1889 an accident occurred to the conduit of the Vanne one of the chief sources of the spring water supply, and all Paris received nothing but river water for five days. It is estimated that this caused 1,570 cases of typhoid fever.

(c) *Other Diseases*.—In addition to Asiatic cholera and typhoid fever a number of other diseases have been attributed with more or less reason to water borne infection. Conspicuous among these is the so-called epidemic diarrhea. Various well defined outbreaks of intestinal disturbance have been traced not infrequently to the use of polluted water. An interesting outbreak of a dysenteric affection ascribed to the use of well water has been reported by Lartigau.⁸ This case is a particularly important one since the micro-organism apparently responsible for the infection (*B. pyocyaneus*) was isolated both from the discharges of the patients and from the contaminated well water.

The most extensive epidemic of this order yet described is one recently recorded by Thresh,⁹ which occurred in the borough of Chelmsford, Eng., attacking about 1,400 persons, mostly adults and causing 14 deaths. The practical limitation of the cases to definite sections of the population first threw suspicion on a certain portion of the water supply. The original sources of supply apparently were not exposed to pollution but a small uncovered reservoir was found into which water from a deep well had been pumped and through which it flowed to mix with water from a spring in a large covered reservoir. The conditions surrounding the small reservoir are thus described: "This small reservoir was not bricked above ground level hence during heavy rain water from the ground around would run into it. Adjoining one end of this reservoir was a patch of garden ground on which flowers were being grown. This I found was manured from time to time with road scrapings. The intimate connection between the onset of the epidemic and a particularly excessive rainfall was shown by the fact that the epidemic commenced between July 23 and 25, while the rainfall records show that after three rainless weeks 0.6 inches of rain fell on July 17, 0.45 on July 19 and no less than 2.1 on July 23. Table 3 sets forth the relation subsisting between the use of the contaminated water and the deaths from diarrhea."

TABLE 3.—Deaths from Diarrhea during epidemic

5,000 persons not using contaminated water	0
7,700 persons using the contaminated water	14
2,000 persons in the remainder of the union not using the contaminated water	0

Less convincing than such well marked outbreaks are the instances that have been reported in which water borne epidemics of typhoid fever have been preceded by a large number of cases of diarrhea. This circumstance has been regarded by some observers as indicating that the ingestion of polluted water causes in some persons a diarrheal disorder with a short period of incubation and in others genuine typhoid fever. A critical re-examination of the evidence however is needed in most of the cases especially since the bacteriological data are strikingly incomplete. It is sometimes alleged further, in communities in which typhoid fever has been rare as in the cities of Chicago and Philadelphia that cases of apparently non-specific diarrhea have been notably more common than in cities supplied with purer water. The so-called attacks of winter cholera should perhaps be placed in this category.

The degree to which infective diarrhea can be rightly ascribed to the use of infected water must be considered a question. Some facts such as those recorded in Table 3

color to the supposition that infection sometimes comes by this channel. The danger must be recognized as a real one, although the relative frequency of water infection under ordinary conditions of infant nourishment has not yet been definitely ascertained.

Both the bacillary and the amebic forms of dysentery are ordinarily water borne infections. Although the two infections are etiologically and otherwise distinct, the sources of infection and the modes of transmission are probably very similar. In both cases the infectious elements are contained in the feces of the patient or convalescent, and the entrance of the bowel discharges into drinking water must constitute the most important mode of dissemination, precisely as in Asiatic cholera.

The somewhat rare affection known as Weil's disease or infectious jaundice has also been definitely traced to the use of polluted water.¹¹ The organism (*B. proteus fluorescens*) concerned in the causation of this disease is discharged from the body of the sick in the urine and feces,¹² and the same prophylactic methods, therefore, are necessary as in typhoid fever.

Anthrax in animals sometimes has been traced to the use of highly contaminated water, notably in a case reported by Diatropoff.¹³ River water may receive anthrax spores through the drainage from tanneries and the like, and when such infected water overflows meadow lands the spores may be deposited and taken up subsequently by grazing cattle. No instance appears to have been recorded of water borne infection in man.

The opinion has often been expressed, especially by physicians in malarious regions, that water derived from marshy districts is the cause of malaria, but there is no real evidence that this is the case. Experimenters who have drunk water taken from swamps in malarial localities have experienced no ill effects, and even the swallowing of small quantities of blood derived from malarial fever patients and known to contain the specific parasite has not produced the disease. Furthermore, the demonstrated dependence of malaria on the bite of certain mosquitoes places the hypothesis of malarial water infection in the region of unverified myth.

It seems quite unlikely also that water ever serves as the vehicle of infection in yellow fever. In this disease as in malaria, the transfer from man to the mosquito and back again to man seems to be the only means of propagation.

In the case of the bubonic plague it is very doubtful whether water plays any rôle in the transmission of the disease. The German Plague Commission was unable to discover evidence of any authentic case of alimentary tract infection in man, and, although perhaps the possibility of water infection can not be altogether excluded this mode of conveyance must be so infrequent as to have little practical importance.

Infection with various animal parasites may sometimes result from the contamination of drinking water, especially in tropical countries. It is stated that the occurrence of the hydatid stage of *Tænia echinococcus* in man is usually due to the swallowing of the ova present in polluted water. The tapeworm form of this parasite inhabits the intestine of the dog and human infection is said to be common in countries where dogs abound, as in Australia and Iceland. Infection with *Ascaris lumbricoides* is also usually attributed to drinking water. The ova of this worm may pass directly from the intestine into sewage, and if such sewage enters a water supply a possible cycle of infection is clear. Other parasites, infection with which is attributed with more or less reason to water conveyance are *Bilharzia hematobia*, *Amelostomum duodenale*, *Trichocephalus hominis* and *Filaria medialis*.

CHAPTER II

SOURCES OF INFECTION

The most common way in which water becomes infected is through admixture with sewage. The infectious elements or disease germs in sewage sometimes may be derived from street washings or from factory waste but in the great majority of cases they enter the sewage directly together with the dis-

charges from the human bladder or intestine. This is notoriously the case with the bacteria of typhoid fever and Asiatic cholera, diseases which are by far the most common as they are the most serious of the water borne infections.

In Asiatic cholera, it is well known that the specific germ leaves the human body in the intestinal discharges in which it is often present in large numbers. It has been shown also that the dejecta in mild and apparently simple cases of diarrhea, occurring in times when cholera is prevalent, may contain myriads of cholera spirilla, and that at such periods, moreover, cholera spirilla have even been found in the intestinal contents of perfectly well and healthy persons. It follows that such persons, migrating from a cholera infected district, although remaining healthy themselves, may be the means of scattering the seeds of infection. Any condition, therefore, chance or otherwise, that allows sewage to mingle with water used for drinking purposes may be the means of originating an outbreak. Those communities into whose water supply sewage enters are, hence, in greater or less peril at all times when cholera is rife in the surrounding region.

The sources of infection in typhoid fever are similar to those in cholera with the addition that the liability of carriage by mild or unrecognized cases is present in even greater degree. The evidence both from epidemiology and bacteriology indicates that the typhoid bacillus remains in the human body longer after convalescence than does the cholera spirillum. This is particularly true as regards its persistence in the urine. The investigations of the last few years have shown that in from 25 to 30 per cent of all cases of typhoid fever the urine contains typhoid bacilli. They are sometimes found here in enormous numbers, and may range as high as 500,000,000 per cubic centimeter (Horton Smith). Examinations occasionally reveal their presence far into convalescence, and it is possible that in rare instances the urine of the patient may remain infectious for years after complete recovery. The broad epidemiologic importance of this fact has only recently become fully recognized. The evacuations of urine are more frequent and copious than the discharges from the bowels, are more highly infectious, and may remain infectious for a longer period. On the supposition that the urine of typhoid fever patients and convalescents may contain the specific bacillus, apparently mysterious cases of isolated infection and even obscure epidemic outbreaks become susceptible of plausible explanation. At least one instance is on record¹⁴ where a well water apparently became contaminated from urine alone, since typhoid bacilli were found in the water without any admixture with colon bacilli, and this would hardly have been the case had any accompanying fecal contamination occurred. The relative facility with which infection may result from the urine of a case of walking typhoid or of a convalescent renders this source of evil a particularly insidious one, and one against which special precautions will doubtless soon be taken more generally both by health authorities and by physicians in private practice. The well known fact that urine can be freed at least temporarily from typhoid bacilli by the administration of hexamethylenamine to the patient has been taken general advantage of, but other methods of disinfecting the urine after passage (e. g. with carbolic acid or mercuric chloride) should not be neglected, especially in view of the fact that the bacilli may reappear in the urine when the hexamethylenamine is discontinued.

Perhaps the most common source of water borne anthrax infection is the entrance into water of anthrax spores discharged in the drainage from tanneries. The spores may become detached in the process of cleansing hides imported from anthrax infected localities. Infection of well water with spores derived from the bodies of dead or diseased animals may also conceivably occur.

In considering the pollution of large bodies of water such as lakes or rivers it has been customary to lay great stress on urban as opposed to rural sources. Thus, emphasis is often placed on the urban or sewered population on a watershed to the relative neglect of the dwellers in rural districts. There can be no doubt that so far as the amount of organic matter entering a river is concerned, the urban population is vastly

¹¹ Jäger Zeits. f. Hyg. 1892 12 p. 525

¹² Conradt and Vogt Zeit. f. Hyg., 1901, 37, p. 283

¹³ Ann. lase., 1893 7, p. 286

¹⁴ Kübler and Neufeld, Zeitsch. f. Hyg. 1899, 31 p. 133

more significant than the rural, but the question of infection is on a different footing. Many scattered farmhouses are provided with outhouses or privies which adjoin, or perhaps overhang small tributaries of the main stream. Disease germs may be introduced from this source, and owing to the relative neglect of disinfection in country districts, this may occur more readily than in urban communities. It may be noted that some of the greatest epidemics of typhoid fever have been caused by infection from rural sources, Plymouth, Ithaca and Butler are familiar examples. There is evidence, further, that typhoid bacilli introduced into water together with abundant organic matter, as in sewage, perish more quickly than when introduced into relatively pure water. From this standpoint also rural infection can hardly be regarded as a negligible quantity.

CHAPTER III

INJURY OF WATER SUPPLY BY ALGÆ AND RELATED ORGANISMS

In certain regions and at certain seasons of year the appearance of disagreeable odors and tastes in drinking water is not an infrequent occurrence. These odors are particularly likely to develop in reservoir or storage basin waters, the affected waters often becoming so disgusting as to preclude their use on the table. It is usually popularly assumed that such odors or tastes are due to the active decomposition of matters of animal origin or even that the nauseous qualities are due to the admixture of sewage with the water. The presence of these odors consequently causes serious concern among water drinkers, but such concern, however, is not altogether justified. The malodorous or unappetizing emanations, which are quite various in character and are often picturesquely described by terms such as 'fishy' are as a matter of fact due to the products of growth, or sometimes to the products of decomposition of microscopic algæ. These products, at any rate in the proportion in which they are found in natural waters are not known to have any prejudicial effect on human life and health. The practical seriousness of the trouble, however, is shown by the fact that some supplies representing large investments, have been rendered almost valueless by becoming infested with algæ. In other cases large expenditures have been found necessary to remedy the evil.

The organisms commonly found producing these odors belong to several distinct groups. Some of them are diatoms, some of them *Cyanophyceæ* (blue-green algæ) and some of them are infusoria. Among the diatoms *Asterionella* has been the genus most frequently associated with the occurrence of unpleasant odors. When this diatom is present in small numbers the odor has been described as aromatic, resembling the odor and taste of the geranium but when it occurs in very large numbers it imparts a distinctly disagreeable, fishy odor to the water. *Asterionella* frequently multiplies in great abundance in pure ground waters which have been stored in reservoirs and which, owing to their nitrate content and their exposure to light and air, afford a highly favorable medium for the development of diatoms. In some cities, e.g. Brookline and Newton Mass., it has been found necessary to prevent the growth of this diatom by roofing over the storage reservoir and so excluding the light that is necessary for growth. Some other diatoms, such as *Tabellaria* and *Meridion* are found to produce disagreeable odors in public water supplies but *Asterionella* surpasses other organisms of this class both in the frequency of its occurrence and the offensiveness of its products. These odors arising from the presence of great numbers of diatoms are due to the products of growth of the living micro organism and not to the products of decomposition. It has been well established that these products of growth are due to oils compounds (essential oils) secreted or excreted during the healthy metabolic activity of the organism.

Among the blue-green algæ (*Cyanophyceæ*) several species have been found implicated in the production of disagreeable odors. By far the most troublesome of these is the genus *Microcystis* the natural odor of which is described as 'mouldy' or 'grassy' but which when the process of decomposition sets in evolves an extremely offensive stench almost universally described as suggestive of the pigeon. This 'pigeon' odor is produced by the decay of highly nitrogenous organic com-

pounds, containing sulphur or phosphorus, of such compounds in fact as those which usually produce the evil smell proceeding from the decomposition of organic matter. Many hygienically excellent and otherwise highly desirable water supplies have been seriously injured by becoming infested with *Anabaena*. Other blue-green algæ which produce nearly or quite as offensive an odor are *Clathrocystis*, *Livularia*, *Coclosphaerium* and *Aphanizomenon*, although they are not found so commonly as *Anabaena* in public water supplies.

Among the grass-green algæ (*Chlorophyceæ*) the general *Tolvoa*, *Eudorina* and *Pandorina* have been found associated with the production of more or less pronounced 'fishy' odors, which, as in the case of the diatoms, are due to the qualities of the essential oils formed during the normal growth of the organism.

In the group of infusoria, *Uroglæna* and *Synura* have proved specially objectionable as inhabitants of water supplies. A number of important public supplies have been rendered practically unfit for use through the presence of *Uroglæna*. Middle town and Meriden, Connecticut, and Norwood and Plymouth Massachusetts, are among the places where the organism has caused much trouble. The disintegration of the organism during its passage through the water pipes is often responsible for the liberation of the odoriferous materials. The water taken from pond or reservoir may swarm with colonies of *Uroglæna* and yet emit no disagreeable odor, while the tap water drawn from supply pipes may be highly offensive. The odor produced by this organism is hence not really one of decomposition although of an intensely offensive character. Other odors of growth have suggested to various observers the odors of ripe cucumbers, rockweed, Irish moss, salt marsh, and even in the case of infusorium (*Cryptomonas*) candied violets!

There is no reason for supposing that the odors and tastes due to the presence of large numbers of any of the microscopic organisms are in any degree dangerous to health. This is doubtless true whether the odor be caused by the products of growth or by those of decomposition. The proportion in which these substances occur in the natural waters in question is so small as to preclude any physiologic effect. In the actual operation of water works, however, the impairment of the esthetic value of water by these micro organisms has often led to considerable expense, and has sometimes placed practically insuperable obstacles in the way of securing a supply that is both palatable and hygienically suitable.

Another micro organism that is related only rather remotely to the algæ and infusoria just under consideration but which has frequently caused much inconvenience in the conduct of water works is the so-called iron fungus or *Crenothrix*. This organism is one of the largest of the higher bacteria and among other peculiarities, is characterized especially by the deposits of oxid of iron in the sheaths of the filament. The growth of this organism on the sides of the pipes and conduits of various public water works in widely separated localities has caused much annoyance. The rapid multiplication of this plant may suffice to cover entirely the walls of a reservoir or drain pipe with a thick felt, portions of which are dislodged at frequent intervals and swept along by the current as small, dark brown flocculent masses. As these appear in the tap water they are extremely unsightly. Decomposition of the particles may occur and produce offensive odor. Small pipes may become entirely clogged by the growth. The famous 'water calamity' of Berlin in 1878 was the first occasion on which the production of trouble was definitely laid at the door of this organism. Other municipal supplies have since been attacked by *Crenothrix*, notably that of the city of Rotterdam, Holland where the *Crenothrix* invasion was thoroughly investigated by the distinguished botanist D. Vries. At Rotterdam the operation of a well conducted and filtration plant has been grievously interfered with by the growth of this organism which indeed is said still to cause trouble in spite of all efforts at its eradication. The cities of Lille, France, Rome, Italy, and some places in this country (e.g. Woburn, Mass. and Hartford, Conn.) have also suffered from the growth of *Crenothrix* in

Clinical Notes

THE PREVALENCE AMONG SCHOOL CHILDREN OF DISEASES OF THE EAR AND THROAT *

W G B HARLAND, M.D., AND G W STIMSON, M.D.
PHILADELPHIA.

A review of the following tabulated results of an ear and throat examination made in one of our largest preparatory schools brings to light some points of practical interest. The examination was systematically carried out, and, as gross defects alone were looked for and recorded, the tables show only such conditions as were undoubtedly harmful to the boys from the standpoint both of physical health and scholastic efficiency. The figures underestimate rather than exaggerate the amount of disease present. It may, perhaps, be said that the number of boys examined is too small to be of great statistical value, nevertheless the figures do give some idea of the relative prevalence of diseases of the ear and throat among school boys of the better class in whom it ought hardly be expected to find any harmful disease that prophylaxis can prevent or medical science cure.

TABLE SHOWING RESULTS OF AN EXAMINATION OF SCHOOL CHILDREN OF THE BETTER CLASS

	39 examined 8 to 10 years of age, per cent.	91 examined 11 to 13 years of age, per cent.	117 examined 14 to 16 years of age, per cent.	50 examined 17 to 19 years of age, per cent.	297 total exam- ined, per cent.
EARS					
Normal	64 10	57 14	53 84	52 00	55 87
Deafness slight, in one or both ears	10 25	20 87	27 34	26 00	22 88
In both ears	2 58	10 98	6 83	12 00	8 41
Deafness marked in one or both ears	7 68	6 58	10 25	6 00	9 09
In both ears	2 58	2 19	0 00	6 00	2 02
History of purulent dis- charge	15 89	14 28	8 54	4 00	10 43
Impacted ear wax	10 25	5 49	2 56	2 00	4 37
NOSE AND THROAT					
Enlarged tonsils including adenoids	28 20	18 12	10 25	8 00	14 98
History of removal of tonsils	8 97	1 09	2 98	1 00	2 85
Abrasion septum (nose bleed)	0 00	3 29	2 56	2 00	2 35
Chronic catarrh of nose	17 97	2 19	4 27	0 00	4 75
Obstructive lesions of nose	3 84	8 23	5 55	1 00	3 87
Hay fever	0 00	0 00	0 00	8 00	1 34
Chronic pharyngitis	5 12	9 89	11 96	6 00	9 42

Looking over the table in detail we find only 55 87 per cent. of these boys had approximately normal ears. The older boys were freer from ear disease than the younger ones, the explanation of which is found in the lower table, which shows a lessening of nose and throat affections as the boys outgrew childhood diseases and tonsillar enlargements—the most frequent causes of ear troubles.

Noticeable deafness for the voice, in one or both ears, occurred in an average of 9 09 per cent. of the boys, a high percentage in view of the handicap such deafness places on a student in his mental development. Impairment of hearing in one or both ears that was readily detected by simple tests was found in 22 88 per cent. of the boys. Impairment of hearing increases progressively up to the fourteenth and sixteenth year, after which it decreases somewhat. This decrease can be explained by the reasons already given above, namely, that they have passed the age when diseases of childhood and tonsillar hypertrophy are prevalent. A sufficient per-

centage of deafness continues into the older years to prove that an "outgrowing" of deafness can not always be counted on.

The percentage of children giving a history of purulent discharge from the ear also becomes smaller as they grow older. It may safely be assumed that the older boys are freer from purulent middle ear disease. For although a larger percentage was affected when they were younger, later on they had forgotten about it, while the younger boys remembered the ear discharge because of its comparatively more recent occurrence. Hearing is not often seriously affected by purulent discharge from the ear, the chief danger lying in the possible extension of the purulent process to the brain.

The filling of one or both ears with ear wax was noted in 4 37 per cent. The percentage of pupils affected was larger in the young and became less as they grew older.

Cases of enlarged faucial and pharyngeal tonsils, the chief causes of mouth breathing and deafness in children, decreases at puberty, but disappearance of the tonsils does not invariably take place. The number of boys giving a history of removal of the tonsils lessens as they grow older, firstly, because many have forgotten about the operation performed in the past, and, secondly, because operation for adenoids and tonsils was not so frequently resorted to formerly as at present.

Examination of the nasal fossae of boys between seventeen and nineteen was not as carefully made as in the other children, a thorough examination entailing too much time and trouble, otherwise it is probable that a higher percentage of defect would be recorded under chronic catarrh of the nose and nasal obstructive lesions in the columns for those ages.

Four out of fifty boys between the ages of seventeen and nineteen gave a history of "hay fever." Perhaps other boys suffered from this affection, but had not yet recognized it in its incipency.

In concluding we are justified in stating that a surprisingly large number of school children suffer from defective ears and throat, and that, therefore, all school children should be subjected to a thorough examination at least once a year. Many of these children are incapable of gleaning the full benefit of their school training because they are retarded in their progress on account of these defects and consequently require a greater amount of attention from their teachers, which is given at the expense of the other boys.

Therefore, it seems that it would be highly beneficial from a standpoint of prophylaxis to require a certificate of examination on a child's admission to the first primary grade, for that is the time when most good can be done in a prophylactic way by removing obstructive adenoids and hypertrophied tonsils. The examination should be made by a capable physician or medical inspector, with itemized reference to nose, throat and ear as well as the rest of the body. If defects were found, although the examiner might not be able to refuse the child admission to the school in case the parents refused the necessary means of correction, he could at least strongly advise treatment and send in with the child a certificate calling attention to each child's individual defect. These children could then be separated from the others for careful observation and frequent examination. If the child, receiving no attention at home, develops a severe attack of earache the teacher could explain to the parents the cause of the condition and perhaps gain their consent to the removal of the offending adenoids and tonsils. In this way the chances of serious middle

*Read before the Philadelphia County Medical Society March 12, 1907.

ear disease with its many complications and sequelæ will be lessened and something will have been done toward lowering the very high percentages recorded in our tables

AMYOTROPHIC LATERAL SCLEROSIS

CLINICAL REPORT OF A CASE.

WILLIAM LITTLETON ROBINS, M.D.

Formerly Assistant Physician Maryland Hospital for the Insane,
Professor of Nervous and Mental Diseases Howard University
WASHINGTON, D. C.

If for no other reason, I would appear to be justified in reporting a case of this extremely rare nervous disease, when the statement is made that this case was diagnosed as locomotor ataxia by as many as five physicians, some of whom reside in various parts of the United States

Patient—J. K., white, married, aged 50, traveling salesman for Ferris wheels and merry-go-rounds, was examined Jan. 19 and 20, 1905. He has two children in good health, and has lost none. In the past ten years he has made seven trips to the tropics (Porto Rico, Cuba, Philippines, etc.), averaging about seven to eight months in each year in a tropical climate.

Family History—Negative. Mother living, aged 87. Father died of chronic bronchitis at 69. One grandparent died from an accident, one died at 85, one at 82 and one at 65. No history of tuberculosis or nervous diseases in the family.

Personal History—At the age of 15 he had a severe attack of pneumonia, and at 20 was critically ill with typhoid fever. Denies syphilis, no evidence of any specific infection. From the age of 20 to 49 he had not been confined to bed on account of illness. Injuries. In 1887, while lifting a very heavy log the bolt in the cant hook broke and his body was suddenly elevated, causing severe pain in the small of the back, which has continued to some extent up to the time of this examination—a period of eighteen years. Patient remarked that since this accident he noticed that "in lifting any moderately heavy weight, the muscles on the right side of the spine" (in lower dorsal and lumbar regions) "would swell up and get very firm, and the small of the back would feel sore for three or four days." He sometimes lived at a "pretty swift pace," drinking heavily at other times drank nothing for weeks. Sexual habits usually moderate.

Present Illness—In the early part of October, 1903 (at the age of 49), patient first noticed a little twitching of parts of the muscles of the right leg from hip to knee, and about three weeks later fibrillary twitchings of muscles of the left arm appeared. Three or four months after this came the fibrillary twitchings of the muscles of the left leg from hip to knee, and several weeks later the twitchings appeared in the muscles on either side of the spine and in the intercostals. A short time after the twitchings began, patient noticed more or less weakness of the muscles affected, and in the case of the arms, intercostals and muscles of the back, atrophy began to appear. With weakness of the intercostals, he noticed that his "lungs would not fill up as readily as formerly." He says that up to date of examination there has been very little twitching of the muscles of the legs below the knees and careful examination failed to elicit any fibrillary movements of the calf muscles.

Patient's Condition Jan. 20, 1905—A man of large frame, who had weighed a year or more previously 235 pounds, now shows at a glance some atrophy of the intercostals and of muscles of the back, neck, shoulders, upper arms and forearms, with wrist drop on each side, the left being more marked than the right. There is also some shrinkage of the muscles of the buttocks and hips, and an apparent hypertrophy of the muscles of the thighs and legs, the contrast between the atrophy of the muscles of the arms, forearms and hands and the normal or slightly hypertrophied condition of the muscles of the thighs and legs being quite marked. There is a peculiar hoarseness of the voice and some fibrillary tremor of the tongue. He is unable to whistle. Fibrillary

twitchings of the muscles of the arms, neck and thighs are noticeable at times. Spasticity of the legs is prominent. He is able to walk with assistance, the gait being markedly spastic.

Physical Examination—This shows the heart normal. Some shortness of breath is present. Pulse 78, temperature 99. Bladder and bowel functions normal, sphincters all intact, and sensory conditions normal. Electric reactions. The left arm shows slight reaction to faradism in the deltoid, biceps and triceps, no response in extensors, but some in flexors of forearm. Little or no response to galvanism, except a tetanic contraction in the deltoid. Right leg. All thigh muscles appear to respond to faradism, the thigh muscles showed marked A C C to galvanism. The calf and other muscles of the right leg below the knee show some response to faradism. Left leg. Practically the same electric reactions as those of the right, but response is somewhat weaker. Eyes. Pupils, vision, fields of vision, and muscular movements normal. Ears. No deformities. Hearing normal in both ears, senses of smell and taste normal, memory good, logical powers good. Emotions. Extremely emotional at times, laughing and crying. Very anxious to get well, but if he must die, insists that he can not and must not be allowed to suffer. Sleep. Awakens about every two hours when he becomes restless and irritable, desiring to be removed from bed to a chair and back again in a short time. Reflexes. Jaw jerk exaggerated. Elbow jerk exaggerated. Knee jerks very markedly exaggerated. Ankle clonus present on left side, not elicitable on right side because of former injury to right ankle joint (fixed joint). Babinski present in both feet. Wrist jerks absent, owing to extreme atrophy of extensor muscles of the forearms. Cremasteric present. Abdominal present.

As time advanced the condition grew progressively worse. The trapezius and other muscles of the neck grew weaker and weaker until he was unable to hold his head erect, a special pillow being arranged to support the head. The voice became so feeble that it was scarcely audible. Fibrillary tremors were often noticeable without tapping the muscles involved. Swallowing and respiration became extremely difficult. Finally pulmonary edema developed, causing death on July 21, 1905, the actual duration of the disease being twenty-two months. An autopsy was urgently requested but was declined.

This would appear to be a typical case of amyotrophic lateral sclerosis. This disease is defined by Starr as a chronic form of spinal paralysis characterized by the symptoms of progressive muscular atrophy in the arms and of lateral sclerosis or spastic paraplegia in the legs. Oppenheim states that in typical cases bulbar paralysis occurs. All of these symptoms were present in this case.

ETIOLOGY

Little is known of the causation of this disease. In this case we have perhaps two possible factors in the etiology, namely, prolonged exposure to heat in the tropics and the sudden wrenching of the spinal muscles eighteen years previous to the first symptoms. Examination of the spine failed to show any curvature or other injury and I am led to the conclusion that this very remote accident was probably not the exciting cause of this condition. Whether prolonged exposure to tropical heat was a predominating factor in the etiology of this case, I am at present unable to determine.

AGE OF ONSET

This case began at the age of 49 years, which is not an unusual age of onset. Collins, who has made an interesting study of nearly all the cases of record, found that of 100 unselected cases 29 occurred between 15 and 50, 30 between 30 and 40, 25 between 50 and 60, and only 2 under 30. McPhedran's case began at 47. Gor-

ANORECTAL FISTULA—PENNINGTON

don reports a case in a boy of 15 with a history of acute anterior poliomyelitis in infancy

DURATION OF THE DISEASE

My case lasted 22 months, which is probably about the average length of this disease. Collins reaches the conclusion that the average duration is about two years. A few of the recorded cases lasted from six to nine months. A very small number lasted four to five years, while one case extended over a period of ten years. McPhedran believes most cases terminate in one year, but the case reported by him lasted two years.

A NEW METHOD OF OPERATING FOR ANORECTAL FISTULA.

PRESERVING THE CONTOUR OF THE ANUS AND THE FUNCTIONS OF THE SPHINCTER MUSCLES
J RAWSON PENNINGTON, M.D.
Professor of Rectal Diseases Chicago Polyclinic.
CHICAGO

I have learned from practical experience that much can be done to preserve the functions of the anal sphincters by operating as follows. The patient having

Fig 1—Diagrammatic fistula and anal canal a complete fistula b tissues between

Fig 2—Diagrammatic c scope of incision on distal (toward the skin) side of the fistula c tissues remaining and undivided d the seton passed around them and tied.

length, may be dissected out and the remaining fibers of the muscle sewed together, thus preserving the contour of the anus and the functions of the sphincters. By operating in this manner no deep sulcus is left to mutilate the anus as there frequently is following the usual incision method of dividing the muscle. Instead of this the contour of the anus is preserved. Should the seton be left *in situ* until the wound is completely healed a small non-secreting fistula will be seen entering the

Fig 3—Diagrammatic full view f incision of fistulous tracts external to sphincter g seton passed through the opening into anal canal and out through anus h

been prepared in the usual manner, the fistula (Fig 1) is injected, when deemed necessary, with a solution of methylene blue (methylthionin hydrochlorid, U S P) or other coloring materials to aid in searching out the course of the tract or tracts. All of the fistulous tracts external to the sphincter are then divided. A probe-pointed director is then passed into the bowel through the remaining tract and an incision is made on its distal side. This incision should extend far enough distally to divide all or a part of the fibers of the external sphincter and in such a direction as to locate the transferred internal opening at or near the anal margin (Figs 2 and 3). Then, turning the knife, make an incision—Salmon's "back cut"—on the proximal side of the tract. A seton is then passed through the opening entering the bowel and tied loosely around the tissues remaining and undivided (Figs 2 and 3). The wound is dressed as after the ordinary incision operation for fistula. At the end of twenty-four to thirty-six hours the wound is redressed, care being taken to dress it so that the opening entering the bowel will be made to heal from the proximal toward the distal

anal canal. This may be left alone or dissected out and sewed together at will. Sometimes this opening will give no annoyance and finally close without further interference. Should the remaining tissues in this case be simply divided without dissecting out the tract and sewing them together, mutilation of the contour of the anus and loss of control to a certain extent would most likely follow. In such a case the entire epidermis-lined tract should

JOUR. A. M. A.
MAY 18 1907

be dissected out and the ends of the muscle united. This may be done either under local or general anesthesia. It is best performed, however, under the latter.

The question might arise: What is the use of the seton? Would it not be just as well, or even better, not to use it? No, for by using it the opening into the bowel is transformed and transferred at the pleasure of the operator and the incision through its use made to heal from the proximal toward the distal side, or, in other words, with it you can direct and greatly control the healing process and the location of the final fistulous tract.

It might be objected theoretically that there would be constant reinflection from the setonized fistulous tract which would be inimical to the healing. Practical experience has not found this to be true. Besides, the tract is washed out daily with an antiseptic solution.

It is the consensus of opinion that the large majority of cases of incontinence following operations for fistula could be avoided if the external sphincter were cut squarely across and the ends sutured together or the postoperative treatment so directed that the ends of the muscle would be slightly separated by the cicatrix. The seton method provides for this procedure.

The anus not being divided aids the healing of the external wound and prevents much of the contraction and atrophy usually observed after these operations.

By operating in this manner we simply have an external wound with which to contend. The anus is not disturbed to any great extent, and in some cases not at all, and the patient is usually up and around in a few days. Moreover, the bowel movements do not soil the wound.

Finally, I have found that the employment of this method of operating greatly aids in preserving the contour of the anus and the functions of the sphincter muscles in operating on many cases of anorectal fistula.

THE BICYCLE PUMP IN INTUSSUSCEPTION

H. T. GOODWIN, M.D.

Surgeon to St. Vincent's Hospital
TOMPKINSVILLE, N. Y.

History—Baby X, aged 13 months, was reported by his mother on the afternoon of Nov. 10, 1907, as having vomited several times during the day and being unable to retain any thing in his stomach. I directed her, by telephone, to give the child calomel gr 1/10 every twenty minutes. At 7 p. m. the mother asked me to see the child, as he was no better. No other than his usual food had been given him, and this had previously agreed with him, as evidenced by his weight, 32½ pounds. He had had one small bowel movement in the morning, prior to this his bowels had been regular.

Examination—I could detect nothing to account for his symptoms. His temperature was normal, there was no tenderness over the abdomen, and but for the frequent vomiting his condition seemed good. Between the attacks of vomiting he was bright, though peevish, and wanted to be carried, which for him was unusual. I directed that the calomel be continued. On the following morning his temperature was 101.6 F., the vomiting had continued and his bowels had not moved. There was still no abdominal tenderness.

Treatment—Calomel gr ¼ was ordered every two hours until four doses had been given. As this produced no effect, the same dose was given every hour until one more grain had been taken. At 3 a. m. the child had one very small bowel movement. On the morning of November 12 there was no further movement. The temperature was 99.6 F. Saline enemas, one pint with the addition of an ounce of glycerin were ordered every three hours. At 11 p. m. Mrs. X. called

me up and asked me to come to the house, as the baby's bowels had not moved, and she was worried about him. When I arrived he still seemed in good condition, but kept his mouth open in a peculiar way, as though he was nauseated, and every few seconds yawned. It was this open mouth and yawning that worried the family. The enemas having produced no result, I had, at 7 p. m., ordered the addition of ox gall to every enema. The abdomen being very soft and free from tenderness, I performed massage, and directed that the enemas be continued, but in larger quantities.

By the morning of November 13 there was still no movement. Child retained albumin water, but was given only a teaspoonful at a time. Vomited occasionally. A mass, which the mother could also plainly feel, was made out in the right iliac fossa, a little below the appendix. Only slightly tender, but pressure produced gurgling. I advised consultation, and Dr. L. E. La Fetra was asked to come over. He arranged to be at the house at 4 p. m. At 1 o'clock I again saw the child. The mass, if anything, was larger, and was now very tender, the slightest touch causing the child to cry. Feeling now certain, of what for the past twenty-four hours I had suspected, that I had a case of intussusception to deal with, I took a bellows, attached to it a catheter, and introducing the latter into the rectum, attempted to inflate the intestines sufficiently to replace the telescoped gut. The bellows worked badly, and my efforts were unsuccessful. One of the boys in the family having a bicycle pump, I substituted this for the bellows. I had the father manipulate the pump slowly and carefully, while I kept up percussion over the abdomen. When I considered that sufficient air had been introduced, I withdrew the catheter, and directed Mrs. X. to wait a half hour and then give an enema. When I returned at 4 o'clock to meet Dr. La Fetra, Mrs. X. informed me that just after the enema the child had had a small fecal movement, and an hour after another. Dr. La Fetra examined the child, but finding no mass asked me to point it out. I attempted to do so, when I was surprised to find that it had entirely disappeared. There was no possible doubt that it was there before the pump was used, as not only I, but the mother, distinctly felt it, and I not only felt it, but distinctly mapped it out. Between 1 and 4 o'clock there had been a wonderful improvement in the child. There was but one conclusion to reach, and in this Dr. La Fetra said he thoroughly concurred, that it was a case of commencing intussusception, and the air driven in by the pump had forced the invaginated gut back to its normal position. That night the child had a large bowel movement, and from then on continued steadily to improve. There was no return of the trouble, and he has since been perfectly well.

54 Richmond Road

A CASE OF VOLKMANN'S PARALYSIS AND CONTRACTURE

FRANCES N. BOYNTON, M.D.
NEW HAVEN, CONN.

In view of the recent publication of an article¹ on Volkmann's paralysis and contracture, giving a history of the literature of the subject and a tabulation of cases, it was thought that the following case, which through the kindness of Dr. E. H. Arnold, I am permitted to report, might prove of interest.

Patient—A L., girl, aged 5½, was brought to Dr. Arnold March 1, 1901, with the left hand and wrist paralyzed and contracted.

History—Family history and personal history up to time of accident five months previous were negative. On Nov. 10, 1900, patient fractured left humerus just above elbow joint. The fracture was reduced and the arm splinted and bandaged. It was not especially painful, but the hand soon puffed up, assumed a wax-like pallor and the fingers began to contract. The attending physician brought another in consultation and

¹ Powers (Charles A.) Ischaemic Paralysis and Contracture of Volkmann. THE JOURNAL A. M. A., March 1, 1907, p. 759.

the bandages were loosened, but not removed for some time. The exact time of removal of splints was not remembered by the mother, but the attending physician told her it was sooner than usual. At this time sloughing was found to have taken place on the anterior aspect of the forearm. The wrist and fingers were flexed and absolutely powerless.

Examination—March 1, 1901, five months after the accident, the conditions were as follows. On the anterior aspect of the left forearm, slightly to the radial side and about two inches below the bend of the elbow, was a scar an inch in diameter. The flexor muscles were short, hard and adherent, the lower part atrophied, changing the contour of the arm. The fingers were flexed on the hand and the hand on the forearm. There was little power of voluntary movement and even passive extension was impossible.

Diagnosis—Ischemic contracture.

Treatment—Previous to this examination there had been some treatment by forcible stretching, but without effect on the contracture. Heat and massage, electricity and passive movements were now advised by Dr. Arnold and after some delay these measures were instituted. Good effect was soon apparent in lessening of the contracture and improved usefulness of the hand, but owing to temporary removal of the patient to another town there have been long intervals in the treatment. Since January, 1907, treatment has been pushed vigorously, and, although six years have elapsed since the injury to the muscle, improvement is noticeable. The treatment now consists of dry hot air, followed by cupping over the scar, effleurage, frictions, pétrissage and vibrations of the muscles, passive stretching and active movements with special apparatus. The muscle bellies are becoming softer and less board like, the lower forearm is rounding out, and the power of extension is increasing. It is still impossible to extend simultaneously wrist and fingers, but the wrist can be extended with fingers only moderately flexed at the terminal joint, and the hand is nearly, if not quite, as useful as its mate. This case is clearly one of Volkmann's paralysis and contracture, i. e., ischemic paralysis due to the pressure of too tight dressings.

In view of the great improvement already noted it would seem that an early institution and vigorous prosecution of appropriate non-operative treatment might have cured the deformity as well as restoring the functional ability. Indeed, even at this late day there is some hope of such a result. Of the cases tabulated by Powers 31 had non-operative treatment. Of these 4 are described as completely recovered, 1 as almost recovered, 6 as having good functional results with deformity, 12 as manifesting slight improvement and 8 as being unaffected by treatment. The case herewith reported falls at present in the third class of good functional results with some deformity. The latter has, however, been so much reduced that it may yet present complete recovery.

A NEW URETHROSCOPE TO BE USED WITH THE AID OF WATER DISTENSION

GEORGE WALKER, M.D.

Associate in Surgery, Johns Hopkins University
BALTIMORE.

The accompanying cut represents a urethroscope based on the broad principles of the cystoscope, but so modified as to enable one to get a lateral view of the urethra and not that of the collapsed wall which we ordinarily see. At first I employed the ordinary tubes in which a window had been cut immediately opposite the prism, but this proving unsatisfactory, it occurred to me to distend the urethra with water and to discard the tube entirely. I then devised the metal cap to be fitted into the meatus. Water distension has proved to be very advantageous and superior in many ways to the tube

DESCRIPTION OF INSTRUMENT¹

The urethroscope is No. 15 French, its full length is 20 cm (8 in.), its length from the outer lens to the prism is 17.5 cm (7 in.), it focuses at $\frac{1}{8}$ inch, at which distance the amplification is 3 diameters. The prism is made after the modern double convex pattern. The lamp is turned around so as to be placed very near the prism, but separated from it in such a way that the setting of the prism does not get too hot. The connection with the cord is made by means of two metal rods, the adjustment at this point being such that a slight turn makes or breaks the connection. The instrument passes through a metal cap which is made so as to fit into the meatus, this piece has a second opening, which is provided with a cock into which a syringe fits and which can be opened or closed by means of the point of the syringe. The syringe is made of metal and holds 6 drams.

MODE OF USING

The instrument is inserted into the urethra and the middle cap slipped down and fitted into the meatus. The glans is then pulled up so as to make the meatus water-tight. The syringe having been filled with water, the point is adjusted into the cap and the urethra is distended. The amount of distension is regulated by the degree of distension as felt by the finger on the outside of the urethra, as a rule 3 or 4 drams are required. The connection is now made and the lamp illuminated. In order to get the proper focus the lower

end of the urethroscope is pressed against the wall of the urethra opposite to the point which is to be inspected. The metal cap is held together with the glans in the left hand and the telescope pulled up and down and rotated so that the whole urethra is passed under inspection. No pain is experienced, no cocaine is necessary and all adult meatuses will admit the instrument easily.

This urethroscope can be used without the metal cap, in which case the urethra is distended with water and the meatus held closed by the fingers, after having been well lubricated with glycerin and a drop of glycerin having been poured on the meatus, the instrument can be slipped in without the escape of any water.

In view of the clear delineation of the blood vessels of the urethral wall and of the glands and follicles I believe that after one is accustomed to it and is able to interpret the pictures it will be found far superior to the urethroscope now in use.

¹ When I presented my idea for the construction of a urethroscope to Mr. R. Wappler of New York I found that he had a small straight cystoscope similar to the one above described. I can not therefore claim originality in the cystoscopic part of my instrument. I wish to thank him for his valuable assistance.

Tuberculosis of the Uterus—Reginald H. Lucy, Plymouth, England asserts that tuberculosis of the uterus is more common than is suspected. He believes that as microscopic evidence accumulates it will be found that many ulcerations of the cervix, hitherto considered malignant, will prove to be tuberculous.—*Jour. Obst. and Gyn. of Brit. Emp.*

The advantages of having charted urine findings in such diseases as diabetes mellitus will readily be seen. Changes in medication in diet and in general management can be watched from day to day and the gross results over a long period compared. The cases can be referred to readily and frequently facts of great interest to both patient and physician noted. For purposes of instruction the chart brings out more forcibly than any other method the important points in the course of the disease. Students are enabled to carry away a definite mental picture of the progress of a case which is far more satisfactory than an array of figures. In some cases the rise in the acid curves might foretell the impending danger from coma. The economic value of having one sheet carry the findings over a period of four weeks may in some instances be worth considering. In private practice such a chart as is here outlined keeps histories from becoming bulky—a fact might encourage one to keep closer watch of the urine.

TONSIL SNARE

EDWARD C SEWALL, M.D.
SAN FRANCISCO

The use of the snare with a cold steel wire for the removal of the tonsil requires an instrument simple in construction and strong in all parts. The instrument here shown covers, I think, these requisites.

No provision is made for the re-use of the same wire because the snare can be so quickly threaded and a loop once used loses its best form. The general shape and mechanism is that of snares that are well known to be satisfactory. The parts have been adapted to the uses to which it is to be put. The canula is strong and has a button on the end to prevent its splitting. The screw for the attachment of the wire is set firmly into a strong

piece of steel, over this fits a button and then a loose washer. Both button and washer are made of chilled steel and milled so that by means of the strong thumb-screw the wire can be secured and quickly fastened. Most snares fail to provide for the quick and secure fastening of the wire, it often being made fast by clumsy and slow twisting. When the loop has engaged the tonsil the wire is drawn taut and then the cutting slowly accomplished by the windlass. This crushes the vessels and makes bleeding less to be feared.

CHRY SOPHANIC ACID KERATO-CONJUNCTIVITIS

CHARLES J KIPP, M.D.
NEWARK, N. J.

The fact that chrysophanic acid or chrysarobin, when applied in the form of a salve to any part of the face and even to other parts of the body, will give rise in some individuals to a conjunctivitis of greater or less severity is known to dermatologists and is mentioned in many text-books on diseases of the skin. Recently this drug seems to have come into favor again, at least I have been told by apothecaries that it is prescribed more frequently now than for several years past, and this is one reason which has induced me to put the following case on record.

Patient—N. C. L., aged 63, in good health, of temperate habits, a clerk by occupation, came to me on May 5, 1906.

Examination—He was led into my office with a bandage over his eyes, and his companion told me that he was blind. I found that the eyelids of both eyes were red, shining and edematous. The edges of the lids were glued together by secretions. After soaking the lashes with warm water, the lids were opened and tears streamed from the conjunctival sac. There was not much secretion in the conjunctival sac. The palpebral conjunctiva was very red and swollen, the bulbar conjunctiva was edematous and intensely injected. The cornea of both eyes were hazy, but the epithelial layer was apparently intact. The pupil was small, but there was no iritis and no disease of the posterior half of the eye. Both eyes were in about the same condition. The patient was complaining bitterly of pain and intense burning in his eyes and of photo-

phobia. He was unable to keep his eyes open long enough to determine the refraction of the eyes and the amount of vision.

History—This is the first time in his life that his eyes have been inflamed. For some years the tip of his nose has been somewhat red from enlargement of the blood vessels in the skin, and this has annoyed him a good deal, especially as he never indulges in alcoholic drinks. He was told that this condition could be removed, and thereon he consulted his family physician, a homeopath, who prescribed a salve which was to be applied to the skin of the nose every night and washed away again the following morning. He applied this salve only once, and on the following morning tried to wash it off, and in doing so he probably got some of it in his eyes. His eyes, which previous to this time had been in normal condition, began to give him pain soon afterward, and the lids began to swell in the afternoon of the same day. The pain and the swelling of the lids increased very much during the following night. He slept but little in consequence of the pain. I saw him forty-eight hours after he had rubbed the salve in his eyes. He showed me the salve he had been using. It looked like chrysarobin salve, but to make sure of its composition I applied to the apothecary who had compounded the salve for a copy of this prescription. It showed the salve to be composed of chrysophanic acid 3*ii* and lard 3*vi*.

Treatment—An examination of the secretion from the conjunctiva showed it to contain a few pneumococci. I advised the patient to apply cold compresses to his lids, a salve of ammoniated mercury to the edges of the lids, and to put a drop of a 0.5 per cent solution of sulphate of atropin and 1 per cent cocaine in each eye six times daily. The cold application failed to give relief, and I substituted for them compresses wet with a warm solution of boracic acid. During the next two days his condition remained un-

changed. I brushed the excoriated edges of the lids with a 1 per cent solution of nitrate of silver once daily. On the third day the epithelium of the cornea was wanting in a number of places, mostly in the horizontal meridian, and in the right eye somewhat more than in the left, and the whole cornea appeared somewhat more hazy. The lids were now less swollen and much paler than previously. On the fifth day the deficiency in the epithelial layer of the cornea extended across the whole cornea and was about 1 mm in width. The adjoining parts of the cornea were decidedly hazy, both eyes were in about the same condition. At this time there was but little secretion from the conjunctiva. On the sixth day the entire lower half of the cornea of the right eye was very hazy. The deficiency of the epithelial layer had not increased in extent. The left eye remained as before. He had but little pain, but the photophobia continued. On the ninth day there was a decided improvement in the condition of the cornea of both eyes. There was less haziness, and the deficiency in the epithelial layer was gradually filling in. On the fourteenth day the cornea were clear and there was no longer a defect in the epithelial layer, the lids were normal or very nearly so, and there was no secretion from the conjunctiva. He was free from pain, but still had photophobia. On the twentieth day both eyes were normal. The refraction was hypermetropia 2 D S 6/5, both eyes alike.

There can be no doubt, I think, that the eye disease was caused by the entrance of the chrysarobin salve in the conjunctival sac. Whether the corneal disease was due to the direct action of the chrysarobin or was caused by the conjunctivitis, I am unable to say. The disease of the cornea certainly made the case a much more serious one, as it endangered the sight of the eye. Fortunately, it passed away without leaving even a slight opacity of the cornea.

With regard to the treatment given in this case, I may add that I should not use cocaine in such a case unless the pain could not be relieved by the other means employed. The tendency to exfoliation of the epithelium of the cornea is always great in such cases and is

doubtless increased by the cocain, especially if the eyes are kept open. In this case the eyes were kept closed for several days and I do not think that the shedding of the epithelium was caused by the use of the cocain. Holocain, which is also a local anesthetic for the cornea, is said to be free from this objectionable quality, but my experience does not confirm this. In most cases atropin and warm applications to the lids is all that is required to subdue the pain.

A primary disease of the cornea as the result of the application of a 20 per cent chrysarobin salve to other parts of the body than the head, beginning after four weeks' use of the salve, is described by P. Krause.¹ In this case a ring-shaped opacity developed in the parenchyma of the cornea, which disappeared in a short time under the use of warm applications and instillation of atropin, but returned after the applications of the chrysarobin were resumed, and again disappeared under the above mentioned treatment in eleven days. He reports also another case in which furrows running radially somewhat like herpetic eruptions on the cornea were present. In this case the eye disease developed on the fifth day after the beginning of the chrysarobin application. The eyes were normal in about a month.

The fullest account of this affection is to be found in the recent work of Lewin and Gullery.² It is there stated that the development of a conjunctivitis has been observed after the external use of chrysarobin even in cases in which it was not applied to the face. In 4 to 5 per cent of patients treated with chrysarobin chloroform solution, a conjunctivitis was observed after twelve to twenty-four hours first in one eye, and a few hours later in the other. In the beginning the patient experiences an intense smarting and burning and edema, unpleasant sensations of heaviness in the eyes. The pain increases, blepharospasms appear, lachrymation is increased, and sometimes there is also a slight degree of photophobia. The conjunctiva of the eyeball and of the lids, especially that of the lower lid, is intensely injected. The conjunctiva of the upper lid may be intact. The cornea need not be affected, although ulcers of the cornea have sometimes occurred in connection with the conjunctivitis. The ante-period of this affection lasts three to four days. The injection of the conjunctiva continues for a longer period. The eyes are normal again after eight to ten days with or without treatment. There is no secretion from the conjunctiva. In the eye last affected the symptoms are usually less severe and disappear more quickly than in the eye first affected. The affection may disappear spontaneously, but may also be followed by unpleasant sequences. This conjunctivitis is to be regarded as a resorptive action, more especially since small quantities of the chrysarobin chloroform solution when introduced in the eye produce a mucopurulent inflammation but such is not the case in the chrysarobin conjunctivitis, also because an infection by means of the fingers could be excluded, because the conjunctivitis reappears with every new application of the chrysarobin and because the resorption from the skin was proved. If chrysarobin enters the conjunctival sac in the form of a powder or as a salve a catarrhal conjunctivitis is developed which may be followed by chemosis and even by ulcers of the cornea.

In the discussion following the reading of a paper

entitled "The Therapeutic Value of Chrysophanic Acid in Dermatology," read by Dr. Charles James Fox,³ Dr. Henry C. Baum said that he thought the chrysarobin should be used on the scalp only in exceptional cases. Kaposi himself had warned his pupils regarding the possible dangers of applying the drug in that locality. Dr. Baum said that he had seen a number of cases of violent dermatitis follow the use of chrysarobin on the scalp. He recalled an instance where a physician had applied a small amount of chrysarobin to a ringworm on the nose of a young woman. It produced a violent dermatitis, which extended to the eyes and culminated in complete blindness. In every instance in which this drug was applied to the face or scalp the case should be watched with the greatest care, and only a small area treated at a time until the individual idiosyncrasy of the patient can be determined. In the same discussion Drs. R. A. McDonald and Edmund L. Cocks said that they had applied the drug to the scalp with very satisfactory results and without producing conjunctivitis. Dr. L. Weiss said that in using chrysarobin on the face and scalp the possible resulting dermatitis could be prevented from spreading by the application of zinc gelatin which acts as a compress.

My patient, after he had recovered from his eye trouble, commented on his own case as follows: "Vanity caused me to apply to a doctor to remove the redness from my nose; his salve did not cost much, but it disabled me for work for three weeks. I have suffered much pain and I still have my red nose."

MALIGNANT TUMOR OF THE TESTICLE

DAVID L. WALMSLEY, M.D.

DETROIT

Two cases of this disease are reported in *THE JOURNAL* February 9 and March 30. I wish to add a third case.

Patient—On July 22, 1906, Mr. W., aged 40, married, one child, healthy up to the present, consulted me for the first time.

History—The case dates back to injury to the right testicle by a baseball during high school days. Pain and swelling followed the injury, and atrophy followed the subsidence of the local symptoms. The left testicle was normal. The man became reconciled to his injury, and being fully developed in every respect, paid no further attention to the deformity until the beginning of July, 1906, when his attention was drawn to it by a feeling of fullness and slight uneasiness of the atrophied organ. His family history is good. I advised close watching of the parts. On September 20 I again examined the patient, finding the atrophied testicle the size of an ostrich egg. The tumor was semisolid, smooth and egg-shaped. Tight, not transmitted, slightly tender on pressure.

Treatment and Result—Feeling suspicious of malignancy, I removed a specimen and submitted it to Dr. F. H. Hayward, pathologist to the board of health, whose examination determined malignancy, and I operated Sept. 22, 1906. The patient made a good recovery and was dismissed with instructions to return for inspection.

Dec. 4, 1906, He returned complaining of slight uneasiness in the stump which he thought was enlarging. I discovered a nodule on the end of the stump and advised removal at once. This, however, was delayed until Jan. 6, 1907, when I removed the cord high up and with it the lymphatic glands and adipose tissue, hoping thereby to ward off recurrence. To date of writing (April 25) there are no indications of recurrence. The patient feels well and enjoys living, were it not for the eternal dread of returning trouble.

UNIFORMITY IN THE STRENGTH OF TETANUS ANTI TOXIN

Tetanus antitoxin is undoubtedly of great value as a prophylactic and immunizing agent, its efficacy having been fully confirmed by both laboratory studies and numerous clinical experiences. It is highly important, therefore, that a standard unit for this serum should be provided such as now renders the administration of diphtheria antitoxin so accurate and satisfactory. The necessity for such a standard is evidenced by the fact that in this country, until recently, there were as many methods of standardizing tetanus antitoxin serum as there were manufacturers.

The standardization of this serum is a very difficult problem, and a vast amount of study has been devoted to its solution. Work on this subject has been carried on in the Hygienic Laboratory of the Public Health and Marine-Hospital Service for the past two years, with the result that a stable tetanus toxin has been obtained. This toxin, when preserved under conditions of absolute dryness *in vacuo*, and in the cold and dark, retains its strength for many months, and under ordinary conditions loses its strength very slowly. A satisfactory official standard is thus made possible, and we note with pleasure that the Public Health and Marine-Hospital Service¹ has now undertaken the important task of establishing an American standard.

As we have previously stated,² the official unit went into effect April 1, 1907, the committee of experts appointed by the Society of American Bacteriologists having recommended that "tetanus antitoxin be standardized by the tetanus toxin furnished by the Public Health and Marine-Hospital Service. The unit is ten times the least amount of serum necessary to save the life of a 350-gram guinea-pig for 96 hours against the official test dose of the standard toxin. The test dose is 100 minimal lethal doses of a precipitated toxin preserved under special conditions at the Hygienic Laboratory of the Public Health and Marine-Hospital Service. It was decided that the minimal immunizing dose for a case of possible infection through a wound should be 3,000 of such units. It was decided that after April 1 the new unit should be adopted by all producers of tetanus antitoxin."

The necessity of establishing uniformity in this respect is strikingly shown in the results of examinations of different serums sold on the market. The units claimed per cubic centimeter by the manufacturers of seven samples varied from 0.1 to 6,000,000 and the units per cc actually contained in these samples, according to the American standard, varied from 2 to 769. It is evident from these figures that there has been a marked difference in the potency of the serum found on the market, due to the great discrepancy in former systems of measurement.

With the adoption of the new standard an accurate dosage of antitetanic serum will be made available for both prophylactic and therapeutic purposes, and more reliable data will be secured regarding its beneficial effects. With the preparation of this standard and its subsequent supervision by the Public Health and Marine-Hospital Service a serum of undoubted purity and definite potency is assured.

THE NOMENCLATURE OF SYNTHETIC MEDICINES

The difficulties and disadvantages connected with the present nomenclature of the rapidly increasing number of synthetic chemicals introduced into medicine is forcibly presented in a recent issue of the *British Medical Journal*. Three phases of the difficulty present themselves. 1. The distinctive and systematic chemical terms are too meaningless to the ordinary physician and too long and cumbersome for common use. 2. The shorter names introduced by the manufacturers are arbitrary and, being protected by registration, are intended to prevent the use of the products of rival houses when the patents expire. 3. If a preparation shows any degree of popularity it is likely to be introduced by other firms under new names so that the multiplicity of names for the same article becomes confusing. Further, it is possible that a substance which has proved unsatisfactory may be again introduced under a new name and be considerably used before its true character and worthlessness is discovered. This has often been done. Frequently, also, a substance is introduced in various countries under different names, therefore, an international nomenclature is needed. As a remedy for these evils it has been proposed that unregistered coined names be provided for the new synthetics and that such names be published in the *Chemist's Annual*, which is a special yearly issue sent to all members of the Pharmaceutical Society of Great Britain.

The question is one that concerns the medical profession more than the pharmaceutical, since the physician must first use the name in prescribing, and while the pharmacist will be justified in using any preparation of the chemical if it is prescribed under a non-protected name, his knowledge of such a name will not justify him in substituting if the physician, ignorant of such a name, has used the protected one chosen by the pro-

¹ Public Health Reports P. H. and M. H. S. vol. xxii No. 3
Jan. 18, 1907, 43.
² THE JOURNAL A. M. A. Jan. 26, 1907, 335.

proprietary manufacturer. Some medium is needed to secure wide publicity of these names among the members of the medical profession. The names should be authoritative, convenient and systematic, but should not indicate, as suggested by the *British Medical Journal*, the therapeutic properties of the drug. In rare cases in which the chemical composition is not too complex a name indicating its derivation might be chosen. That something should be done no one will deny, but just what, and how, is a difficult problem to solve. Conditions are getting to be almost unbearable, new names are coined daily, and no one is consulted, except as suits the manufacturer or the one who introduces the product.

The coined names themselves are very often misleading, giving false indications of origin or quality, and under the Food and Drugs Act such names as these are excluded from interstate commerce. The chief difficulty is the property right in a registered name. This opens up an inviting field of gain by permitting the sale of the same article under as many different names as the imaginative manufacturer can create. The whole system is intolerable from the scientific view of medicine and pharmacy.

Until recently there has been no person or organization that could take up the matter. At present the Council on Pharmacy and Chemistry, if it were authorized to do so by the American Medical Association, might take up the subject and work it out. Or some central body might be organized which would represent the American Medical Association, the American Pharmaceutical Association, the American Chemical Society, the Society of Chemical Industry and the Committee of Revision of the United States Pharmacopeia. In this way definite, practical results would follow and an end be put to the hopeless confusion that now exists.

MEDICINAL FOODS

The report on medicinal foods by the Council on Pharmacy and Chemistry of the American Medical Association, which was printed in *THE JOURNAL* last week (page 1612), contains information of vital importance to all practicing physicians. In order that when they use these preparations they may do so on a rational basis, it would indeed, be well if every doctor in the country would read and read again, first, the report of the Council, and then as a comment thereon Dr. Edsall's letter in this issue (page 1694). It has been said that publicity is the best remedy for certain public evils. The facts in regard to so-called medicinal foods—their failure to measure up fully to what has been and is claimed for them, their great relative cost, their dangerous alcohol content, and the likelihood that some physician following

blindly the optimistic suggestions of those commercially interested will do his patients harm—these facts are now public, and every intelligent physician who becomes familiar with these facts may be counted on to take the necessary steps to guard himself and his patients against placing more confidence in these articles than they deserve.

But, in order that publicity in this case shall have the desired effect promptly and decisively, it must be made general and the facts, humiliating as they are, must reach the rank and file of the profession all over the country. In view of the importance of this matter it is nothing less than a duty that those who, as active workers and leaders, are committed to the promotion of general professional efficiency and progress, take special pains to direct the attention of their colleagues to the facts now presented in regard to medicinal foods. Clearly greater general interest must be taken in the homely but important subject of dietetics. The manufacturers have shown themselves very active dietetic teachers, but the place assumed by them should be reclaimed by the therapist, who should take deeply to heart Dr. Edsall's plea for greater exactness and thoroughness in dietetic teaching and practice.

On the other hand, let us as physicians not forget to take on ourselves the blame which lies at our door. Some of these manufacturers have stated exactly the content of the products, and the physician is presumed to draw his own conclusions as to whether it is possible for the products to do what the manufacturers claimed for them. It should be further said to the credit of some of the manufacturers that when the Council called their attention to certain statements they readily complied with the suggestion to modify such statements.

This general subject was taken up by the Council, and a special committee appointed to report on it, because when it faced the problem of passing on certain of these articles, it realized that it was a problem that did not apply to one product only but to all as a class. The results of the experimental work of the committee and its deductions and conclusions will of course not be startling or new to those who have been especially interested in the question, but it is the first time that the subject has been brought directly to the attention of the medical profession in a practical manner. We understand that some of the products mentioned in the table will be approved by the Council but in the description published in *New and Non Official Remedies* a definite statement will be made not only as to the alcoholic content, but as to the caloric or actual food value of the product, so that the physician will be able to use his judgment as to whether or not it is what he wants in individual cases.

LATIN DERIVATIVES IN MEDICAL WRITING—THE USE OF THE INTERNATIONAL MOTHER TONGUE

The attention of medical writers is directed to the interesting plea on page 1714 for the use of Latin derivatives in order to facilitate the reading of articles by foreigners. The immediate advantages of the plan are so evident and they are so well stated in the "plea" itself that further elaboration really is unnecessary except by way of emphasis. The importance of exact titles for medical and scientific articles has often been discussed. Many an important observation has escaped deserved notice and remained buried in the literature deprived of opportunity to influence the development of knowledge because of misleading, incorrect or inadequate title. On account of the enormous extent of the current medical literature of the present day, it is more important than ever that the title should reveal at a glance the special topic and the scope of the article. Otherwise the article is likely to remain unnoticed by those who would profit most by it and who would make the best use of it, namely, the special worker in the same special field as that with which the article is concerned. Exact, specific titles also help to lighten the labors of librarians and of others who perform the useful functions of indexing medical literature so as to make its contents readily available for the student. Furthermore, the effort on the part of the author to formulate an expressive title—often a difficult task—may serve to concentrate the attention on the construction and order of his article and on the important question, only too commonly neglected, whether the article conveys in the briefest form consistent with clearness the real message he desires it to bring. Now, in view of the increasing extent as well as importance of American medical literature, our authors certainly will further its recognition and, what is more important, aid general scientific progress by the use, especially in the titles of their articles, of terms the meaning of which is grasped readily by educated physicians elsewhere. The value of cooperation in medical progress needs no emphasis and by proper attention to details like those spoken of here medical writers will do much to promote general cooperation.

THE ARMY MEDICAL DEPARTMENT

Although the Fifty-ninth Congress enacted some useful measures which had long been desired and needed by the country, the credit due therefor is somewhat offset by its neglect to grant relief in other directions, and among the latter the failure on the part of the lower house to provide a more effective organization for the Army Medical Department can not be regarded otherwise than as a very grave omission. This failure is entirely due to the action of Mr. Cannon, the speaker, who for some occult reason has either failed to understand the necessity for the legislation, or understanding it, has some personal reason for not favoring it. The Army Medical Department was reorganized in February, 1901, at which time the Army was largely increased, the peace footing being placed at 60,000 men and that for war at 100,000, while the medical department was organized for an army of only 40,000 men. Moreover, the lower

ranks in the medical department were increased out of all proportion to the upper ranks, so that now as regards the prospect of promotion the department offers less inducements than any other in the Army. Owing to the shortage of commissioned medical officers it is necessary to employ from 150 to 200 civilian physicians by contract to supply the existing deficiency. The necessity for relief in this matter is patent and urgent. The medical profession of the country, as represented by the American Medical Association, has time and again urged that the needed law be enacted. The President, Secretary Root, Secretary Taft and others have urged it. The Senate passed the bill twice and the House was willing to pass it, but the speaker refused to let it come up. Mr. Cannon is, therefore, wholly responsible for its failure and on him must rest the entire blame and responsibility. It is impossible to get competent young physicians to fill the vacancies in the grade of assistant surgeon, notwithstanding that every possible effort has been made to do so. The number of candidates for these positions this year is surprisingly small. The War Department believes the explanation of this is to be found in the neglect of the medical department by Mr. Cannon, the speaker of the House, and that unless the condition of the Army Medical Corps is improved it will be more and more difficult to fill the vacancies.

A REMOTE DANGER OF PARAFFIN PROSTHESIS

A few cases are coming to light which indicate a possible accident from the use of paraffin for prosthetic purposes, which might have been anticipated, but which apparently has been entirely overlooked. This consists of a connective tissue overgrowth at the site of the paraffin injection, as a result of the long continued slight irritation produced by the presence of the paraffin. Heidingsfeld¹ has recorded two cases of this sort in which paraffin had been used by "beauty doctors" for the removal of wrinkles or hollows about the face and neck. In these two cases there had developed at the site of the injections reddish tumor-like masses from the size of a pea to that of an English walnut and of the appearance of keloids. A similar case was recently shown at the Chicago Dermatological Society by Armsby. In this case a beautifier had injected paraffin into the lower lids and between the eyes to remove wrinkles. The result was eminently satisfactory for about a year, then, however, tumors began to develop at the sites of the injections, and when the patient was exhibited there existed in either lower lid and in the glabella an oval tumor of the size of a large olive. These masses were hard and dense, the skin over them was of a purplish color and they bore a striking resemblance to sarcomata. At the time that this patient was shown the tumors were still growing and had been increasing in size for several months. The amount of deformity produced by these large purplish swellings can readily be imagined. Sections from these cases show a connective tissue overgrowth, like a granuloma, with many giant cells and other evidences of a chronic inflammatory process produced by a long-continued irritation of low grade. The tumors present

many similarities to keloid and it is possible that their treatment will be by no means satisfactory. These accidents, of course, belong in a different category from those in which deformity is produced from the unskilful use of paraffin or from accidents which result in the deposition of the paraffin in improper places or to an excessive amount. The formation of these tumors is an accident which can not be guarded against or prevented, and the accidents suggest that before one uses paraffin for the relief of trivial troubles like wrinkles he should ponder the possibility of an untoward result. In fact, this possibility makes it exceedingly questionable whether the use of paraffin prosthesis is justifiable for the treatment of slight cosmetic troubles.

Medical News

ALABAMA.

Personal.—Dr M L Tidwell, Evergreen, has been assigned to duty as an interne at Bryce Hospital, Tuscaloosa.—Dr Willis W Scales, formerly quarantine physician at Fort Morgan, has been assigned to duty at Colon, Panama.—Dr Gregorio M Guiteras has taken charge of the Marine Hospital, Mobile.—Dr James J Peterson, Mobile, is reported to be dangerously ill with appendicitis at the Inge Bondurant Sanitarium.

CALIFORNIA.

Commencement.—The commencement exercises of Cooper Medical College, San Francisco, were held May 8. The address of the evening was delivered by Rev George W Stone and a class of 23 was graduated.

Spinal Meningitis.—Spinal meningitis is reported to be epidemic in the Sacramento Valley. A largely attended meeting has been held in Woodland to investigate the cause of the disease and to discuss the situation.

Society Meeting.—Butte County Medical Society, at its annual meeting in Chico, elected Dr Buchanan Caldwell, Biggs, president, Dr Lewis Q Thompson, Gridley, vice president, Dr Ella F Gatchell, Chico, secretary, treasurer, Dr Oscar Stansbury, Chico, censor and delegate to the State Medical Society, and Dr Labon C Perdue, Chico, alternate.

Personal.—The Board of Health of Chico has organized with Dr John W Harvey as president, and Dr Wasley, health officer (re elected).—Dr O D Hamlin, chief surgeon of the Oakland Receiving Hospital, has been given 90 days leave of absence and will visit the Atlantic seaboard.—The City Council of Alameda has appointed the following board of health: President Dr J Emmet Clark, Drs Harold A Miller, James K. Hamilton and Ernest M Keys. The board has appointed Dr L W Stidham city physician.—Dr Ernest Barry, San Francisco, while visiting in Monterey April 26, fell from a balcony, fracturing the pelvis.—Dr John H Kuser, Novato, has been appointed physician of Marin County, vice Dr William J Wickman, San Rafael.

Hospital News.—The University of California Hospital, San Francisco, was opened to receive patients, April 15. The institution has a capacity of 42 patients and the attending staff includes the faculty of the University of California Medical Department.—The Saint Catherine's Hospital, Redding, will be completed early in September at a cost of more than \$20,000. It is a two story and basement structure 56 by 72 feet in the mission style of architecture. There will be two wards of six beds each and also ten private rooms.—The Santa Monica Bay Hospital, erected by a corporation composed of local physicians at a cost of \$25,000 with a capacity for 25 patients will be open to the public early in May.—The Mammoth Copper Company has completed a hospital with two private wards and a ward containing eight beds with accommodation for operating rooms for physicians and nurses at a cost of \$10,000 at Kennett.—The cottage hospital at San Rafael was formally opened May 9. The medical staff consists of Drs Harry O Howitt, William J Wickham and William F Jones.

DISTRICT OF COLUMBIA.

March Mortality.—During March 1,558 deaths were reported 42 less than in February, 69 more than in March 1907 and 308 more than the average number of deaths for the

month during the five years preceding. This is equivalent to an annual death rate of 18.06 per 1,000. The deaths reported from infectious diseases were 293, or 18.8 per cent of the total mortality. Chief among the death causes were pneumonia, 242, nervous diseases, 173, heart diseases, 165, consumption, 143, influenza, 87, accidents and violence, 78, and bronchitis, 63.

To Help Internes.—Commissioner McFarland has provided a plan to improve the status of internes at the Washington Asylum Hospital which provides for their promotion to resident physicians and physicians to the poor. The plan provides that internes shall be appointed by competitive examination, that when an interne has served one year and passed the district examining board and licensing board he shall be promoted to the position of resident physician for six months; then he shall be transferred to the Home for the Aged and Infirm for a like term, and then to the Tuberculosis Hospital serving six months as a resident physician. If, at the end of this time his record moral and professional, is good, he shall be appointed physician to the poor.

GEORGIA.

District Society Meeting.—The next meeting of the Sixth District Medical Association or Georgia will be held at the Wigwam Hotel, Indian Springs, June 12.

Change in Medical Journal.—Dr Miller B Hutchins, Atlanta, has disposed of his entire interest in the *Atlanta Journal Record of Medicine* and retired from its management May 1.

Tuberculosis Prevention.—The Atlanta Sanitary and Tuberculosis Prevention Society was organized May 6, when a constitution presented by a committee consisting of Drs Rufus R Kime and J E Summerfield, and Eugene Mitchell was presented for adoption.

Medical Club Formed.—An organization known as the Emory Club was organized March 21 by the students of the Atlanta School of Medicine. The club is composed of graduates of Emory College and will work in the interest of that college and of the Atlanta School of Medicine.

In Memory of Pioneer Anesthetist.—At a meeting of the Jackson County Medical Society, held in Jefferson, April 10, a monument to the memory of Dr Crawford W Long was presented by the society to the city of Jefferson and Jackson County. The monument is to be erected on the spot where Dr Long first performed a surgical operation under anæsthesia.

Commencement Exercises.—The commencement exercises of the Medical College of Georgia, Medical Department of the University of Georgia, Augusta, were held May 1 when a class of 21 was graduated. Diplomas were presented by Chancellor David Barrow, and the address of the evening was delivered by Rev S R Belt.—The annual commencement exercises of the Atlanta College of Physicians and Surgeons were held April 27, and a class of 37 received diplomas. The address of the evening was delivered by Hon Robert C Altom and the diplomas were conferred by Judge Howard Van Tassell.—The commencement exercises of the Atlanta College of Medicine were held April 23 when a class of 20 received diplomas from the hands of Bishop C K Nelson, vice president of the board of trustees. Rev James W Ice delivered the annual oration.

ILLINOIS.

Maternity Opened.—The Elizabeth Williams Memorial Hospital the maternity department of the Evanston Hospital just completed at a cost of \$25,000 was formally dedicated May 9.

Smallpox.—A case of smallpox has occurred at Pushville, said to have been imported from Beardstown.—On account of the prevalence of smallpox at Tremont the commencement exercises at the high school have been postponed.

Personal.—Dr and Mrs Robert A Noble Bloomington have returned from abroad.—Dr Frederick W Werner, who has been ill with scarlet fever is reported to be improving.—Dr T J Fenton, Philo, is reported to be critically ill at the Burnham Hospital, Champaign.—Dr Leigh J Schwartz, Highland Park, sailed for Europe May 2.

Civil Service Examination.—The State Civil Service Commission announces that it will call an examination for assistant physicians in the hospitals for the insane, interne and possibly a psycho-pathologist in June. The positions pay from \$75 to \$125 per month and board in the majority of cases. The position of psycho-pathologist will at least pay not less than \$2,000 a year. The positions are to be

located at Kanlakee and the psycho pathologist will live there

Society Meetings—The thirty first annual meeting of the Brainard Medical Society was held at Lincoln, April 25, jointly with the Logan County Medical Society. The following officers were elected: President, Dr Calvin C Montgomery, Lincoln, vice presidents, Drs Archibald G Servoss, Havana, Don W Deal, Springfield, and John W Bozarth, Mount Pulaski, secretary, Dr Harry S Oyler, Lincoln, treasurer, Dr Charles C Reed, Lincoln, and censors, Drs John M Wilcox, Clinton, William A. Mudd, Athens, and Charles M. Noble, Bloomington. —At the thirty third annual meeting of the Central Illinois District Medical Society, held in Pana, April 20, the following officers were elected: President, Dr Frank P Auld, Shelbyville, vice presidents, Drs Ben B Griffith, Springfield, and Don W Deal, Springfield, treasurer, Dr John N Nelms, Taylorville, and secretary, Dr Roscoe C Danford, Pana. —At the regular monthly meeting of the Champaign County Medical Society, April 11, the following resolutions were unanimously adopted

WHEREAS In certain parts of the county fees are allowed for treatment of pauper cases, while in other parts of the county the payment is refused be it

Resolved, That it is the sense of this society that operation fees and full fees for attendance be charged for treating pauper cases on orders from supervisors be it further

Resolved That this resolution be binding on the members of this society immediately on its adoption be it further

Resolved That a committee of three be appointed to confer with the board of supervisors at their next meeting

Chicago

Bequest to Hospital—By the will of James Henry Smith, \$100,000 is bequeathed to St Luke's Hospital, of which he was a trustee

Contagious Diseases—During the week ended May 11, 99 cases of scarlet fever, 66 cases of diphtheria and 117 cases of measles were reported. Measles and whooping cough are reported to be very prevalent

Promotions in University of Chicago—Dr Robert R. Bensley has been made professor of anatomy, Edwin O Jordan professor of pathology and bacteriology, and Drs Horace T Ricketts and Norman M Harris assistant professors in pathology and bacteriology

Personal—Dr Albert I Bouffleur has returned after a few months in California. —Dr and Mrs Alfred C Croftan are visiting in Pasadena, Cal. —Dr William H Knapp is reported to have been seriously injured in the accident on the Mexican Central Railway, at Bermejillo, Mexico, May 11

Deaths of the Week—During the week ended May 11, 47 fewer deaths were reported than during the previous week the respective numbers being 717 and 764, equivalent to annual death rates of 1774 and 1890 per 1000 respectively. Pneumonia caused 153 deaths, consumption, 92, heart diseases, 59, nephritis, 49, violence, including suicide, 46, cancer, 31, diphtheria and scarlet fever, each 10, whooping cough, 8, typhoid fever, 6, and influenza 5

INDIANA

State Association Meeting—The fifty eighth annual meeting of the Indiana State Medical Association will be held at Indianapolis, May 22, 23 and 24

Society Meetings—At a meeting of the Eighth District Medical Association, held at Union City, April 18, Dr General W H Kemper, Muncie, was re elected president, Dr Maynard A Austin, Anderson, was elected secretary treasurer, Dr Etta Charles, Summitville, censor, and Dr Frank G Keller, Alexandria, committee on arrangements. —At a meeting of the Third District Medical Association held in Bedford, Dr Charles P Cook, New Albany, was elected president, and Dr William C. Cauble, Salem, secretary

KANSAS

Personal—Dr Matthew R. Mitchell has been appointed city physician of Topeka. —Dr Charles B Van Horn has been made president, Dr Matthew R. Mitchell, secretary, and Dr Max Stout, a member of the Topeka Board of Health. —Dr William S Fleming, Arcadia, sustained serious bruises in a runaway accident April 23

Graduation Exercises—The seventeenth annual commencement exercises of the Kansas Medical College, Medical Department of Washburn University, Topeka, were held April 16, when a class of 14 was graduated. Dr William S Lindsay, dean of the college, conferred the degrees, and the address to the graduates was delivered by Dr Henry B Ward, Lincoln, dean of the Medical Department of the University of Nebraska

Communicable Diseases—During the first quarter of 1907 317 cases of measles were reported in Topeka. —Smallpox is reported at Buffalo Gap, Sycamore, Avoca and Stamford. —Two cases of smallpox have occurred among the convicts at the State Prison, Lansing. —On account of a case of smallpox in Elmdale, April 26, the city schools were closed. —The prevalence of measles in Kansas City threatens the closure of the public schools. During the last week of April six deaths resulted from the disease, and on the first two days of the week 52 cases were reported. It is believed that there are at least 400 cases in the city

KENTUCKY

Delegate to Milk Commission—The milk commission of the Jefferson County Medical Society has appointed Dr Henry E Tuley a delegate to the Conference of Milk Commissions of the United States, to be held at Atlantic City June 3, at which time an association will be formed. Dr Henry L. Cort of Newark, N J, is temporary chairman

Personal—Dr Homer Blaine, mayor of Cadiz, has been appointed captain and assistant surgeon, Ky N G, and assigned to duty with the Third Infantry. —Dr Henry C H Gunkel, Newport, fractured two of his ribs in a fall down stairs May 3, and, on account of his advanced age, his condition is considered serious. —Dr George W Ronald, Louisville, is reported to be critically ill with congestion of the brain

Tuberculosis Dispensary—The dispensary for tubercular patients, established under the auspices of the Kentucky Anti Tuberculosis Association, will open June 1. The committee reports that a suitable house has been found on Chestnut Street, between Brook and Floyd. No patients will be housed in the building, but individuals suspecting that they have tuberculosis will come to the dispensary to be examined by the physician on duty

State Hospital Changes—Announcement has just been made of the following appointments by the State Board of Control of Charitable Institutions: Dr Lewis H Mulligan, Lexington, superintendent at the Central Kentucky Asylum for the Insane at Lakeland, Dr J W Stephenson, Todd County, superintendent at the Western Kentucky Asylum for the Insane at Hopkinsville, and Dr Alexander Bailey of Franklin County, superintendent of the Feeble Minded Asylum, Frankfort, to fill vacancies caused by resignations. The board also formulated rules for the governing of the institutions under their charge, business methods according to the system of an audit company have been installed in all, and they will be controlled from the central office. The institutions have been placed in the complete charge of the superintendents

MARYLAND

Baltimore

Disposition of Tuberculosis Fund—The Maryland Association for the Prevention and Relief of Tuberculosis will use the fund of \$10,000 recently raised to maintain three tuberculosis nurses, to display throughout the city and state a tuberculosis exhibit with daily addresses by the secretary, to distribute literature and to establish two or three tuberculosis dispensaries

Personal—Dr Henry Barton Jacobs sailed from New York for Europe May 8. —Dr David Street was thrown from his carriage in a collision May 9, and severely bruised. —Dr William N Hill is head of the "mosquito brigade" sent out by the health department. —Among the medical men who will receive honorary degrees from the University of Maryland at the approaching centennial are Drs William T Councilman and J Homer Wright, Boston, Major James S Carroll, surgeon U S Army, Dr J Ford Thompson, Washington, D C, Drs Charles P Noble and Alexander C Abbott Philadelphia, Drs Nathaniel G Keirle and Thomas C Gilchrist, Baltimore

MASSACHUSETTS

Scarlet Fever Closes Schools—On account of the existence of scarlet fever the Mary A Livermore grammar school Melrose has been closed for four days. —The prevalence of scarlet fever among the students and attendants at Lawrence Academy, Groton, caused its closure on May 3 for ten days

To Investigate Light in Schools—As a result of numerous complaints that the coloring of the walls and the bad lighting of the English High School were injurious to the eyes of the pupils the Boston School Board has appointed a committee to investigate conditions and report to the board. The committee includes two expert electricians and Drs George S Derby, Frank I. Proctor and Miles Standish

MICHIGAN

Graduation Exercises—The eleventh annual commencement exercises of the Grand Rapids Medical College were held May 2, when a class of ten was graduated. The address was given by Dr. George L. McBride, and the degrees were conferred by Dr. Francis J. Lee.

Communicable Diseases—More than 200 cases of measles are reported at Elmira. More than one fourth of the school children of Morris are reported ill with measles. The physician of Houghton County announces a number of cases of smallpox in Houghton, Keweenaw and Baraga counties. Two students at the State Normal College, Ypsilanti, have smallpox.

Personal—Dr. and Mrs. Theodore E. Sands, Battle Creek, returned from Europe April 20. Dr. A. Marion Allen, the oldest practitioner of Adrian, has decided to retire from active practice. Dr. C. Henri Leonard, for more than 25 years a member of the faculty of the Detroit College of Medicine, has been made emeritus professor of the diseases of women and clinical gynecology.

MISSOURI

New Hospital—Work has begun on the new St. Mary's Hospital, Kansas City. The plans call for a three-story and basement structure, to cost about \$200,000.

Interne Examination—A competitive examination for positions at the St. Louis City Hospital will be held by the board of health May 20. Thirty-two appointments will be made following the examination, which is open to students of the various medical colleges of the city.

Graduation Exercises—A class of 26 was graduated at the thirtieth annual commencement of the Ensworth Central Medical College, St. Louis. The address of the evening was delivered by Rev. Sanford P. Cresap, and Dr. Jacob Geiger, the dean, conferred the degrees. The annual commencement exercises of Barnes Medical College, St. Louis, were held May 11, when a class of 76 received diplomas. The alumni banquet of the college was held May 7.

Personal—Dr. Walter C. G. Kirchner assumed charge of the St. Louis City Hospital May 1, vice Dr. John Young Brown, resigned. Dr. Henry S. Brookes has succeeded Dr. Eugene T. Neville as surgeon to the St. Louis fire department. Dr. David W. Scott, St. Louis, was run over by a wagon May 1, while attempting to save a small child from being run over. Dr. Elms Potter Lyon has been elected dean of the medical department of the St. Louis University, vice Dr. Young H. Bond. Dr. William G. Moore has been re-elected vice dean. Dr. William B. Winn has been confirmed as assistant health commissioner of St. Louis. Dr. G. W. Wise Robinson, Kansas City, has been made superintendent of State Hospital No. 1, Nevada, vice Dr. Larkin H. Callaway. Dr. Frank Devilbiss Eugene, has been chosen assistant physician at the hospital, vice Dr. V. A. Williams, resigned.

NEBRASKA

Medicine Vendors Barred—Itinerant medicine vendors have been barred by the city council from obtaining licenses to sell their wares on the streets of Omaha.

Personal—Dr. Lorenzo C. Voss has been appointed city physician of Columbus, vice Dr. Charles H. Platz, resigned. Dr. George L. Miller, Omaha, has resigned as president of the Nebraska Humane Society.

Commencement—At the annual commencement of the Creighton Medical College, Omaha, May 4 a class of 37 was graduated. At the banquet which was given the graduating class and alumni, Dr. Henry B. Jennings, Council Bluffs, Iowa, was toastmaster.

NEW YORK

Signed by the Governor—The governor has signed the Dunn bill providing that managers of state charitable institutions who fail to attend the meetings of their boards or to make visitations for three successive months, shall be deemed to have vacated their positions unless the absence is excused by the governor.

Two Anticocain Bills Passed—Without discussion or opposition the senate passed the bill making it a felony to sell cocaine and eucain except on a physician's prescription, also the Whitney bill which also prohibits the sale of these drugs except on a physician's prescription but provides a different system of prosecution and less severe penalties.

Hearing on the Medical Board Bill—A hearing on the bill which proposes to create one medical board of examiners for all schools of medicine was held before the governor on May

9. The homeopaths and eclectics bitterly opposed the bill on the ground that it is class legislation. The speakers for the bill included Drs. Arthur Root of Albany, for the Medical Society of the State, Frank Van Vleet of New York, for the Medical Society of New York, and Howard J. Rogers.

Recommends Long Lease of Ward's Island—The Hospital Commission, at its last meeting, recommended that a fifty years' lease of Ward's Island to the state be entered into by the city on condition that the state construct on the island a modern hospital for the insane poor of the city. This commission has been in existence for about a year, and one of its tasks is to decide what to do about a new Bellevue Hospital and to simplify hospital regulations. It will recommend whether a central hospital to take the place of Bellevue be constructed at a cost of twelve to fifteen million dollars, using the site now occupied by Bellevue, or whether the money shall be spent in erecting three or four hospitals in various parts of the city.

New York City

Large Gift to Hospital—The will of the late James Henry Smith bequeaths \$100,000 to the Orthopedic Hospital. The testator was a trustee of the hospital.

Hospital Removal Bill Vetoed—Mayor McClellan disapproved of the bill passed by the legislature to prevent the removal of dying patients from different hospitals to Bellevue.

Mayor Approves of Milk Stations—Mayor McClellan has signed the resolution adopted by the Board of Aldermen asking the Board of Estimate and Apportionment to issue special revenue bonds for \$8,000, the proceeds to be used for the erection of milk stations in the parks.

Alleged Unlicensed Doctors Held—Charles Conrad and Paul Schmitt were arraigned before the Yorkville police court charged with practicing medicine without a license. It is alleged by the prosecutor of the County Medical Society that the men posed as physicians and claimed that they could cure glanders.

Police Surgeons Districted—The twenty-five police surgeons who make up the medical corps of the police department and who heretofore have been compelled to go from one end of the city to the other, according to where police men lived will hereafter have to attend only men living in districts to which they have been assigned.

Changes in Faculty—At a meeting of the faculty of Columbia University, the resignation of Dr. George H. Fox, professor of dermatology, was accepted. Dr. Francis Huber was appointed professor of clinical medicine, Dr. Frederick Peterson professor of psychiatry, Dr. Andrew J. McCosh professor of clinical surgery and Dr. Pearce Bailey, adjunct professor of neurology.

Contagious Diseases—There were reported to the sanitary bureau for the week ended May 4 492 cases of scarlet fever with 19 deaths, 445 cases of tuberculosis with 180 deaths, 534 cases of measles, with 12 deaths, 342 cases of diphtheria with 38 deaths, 88 cases of typhoid fever with 23 deaths, 56 cases of whooping cough with 9 deaths, 27 cases of cerebro-spinal meningitis with 20 deaths, 74 cases of varicella and 3 of smallpox making in all 2,061 cases with 310 deaths.

Personal—Dr. Robert W. Hall and Dr. John J. White have been appointed fire surgeons at salaries of \$3,300 a year. Dr. J. Bayard Clark sailed for Europe on the *Blücher* May 11. Dr. Joseph D. Bryant had the degree of doctor of laws conferred on him by the chancellor of the New York University at a meeting of the faculty of the University and Bellevue Hospital Medical College April 30. The Medical Society of Athens Greece in recognition of the labors of Dr. Achilles Rose in medical onomatology has elected him a corresponding member. Dr. Louis W. Bremerman has resigned as associate professor of genitourinary surgery in the New York School of Clinical Medicine on account of his removal to Chicago.

NORTH DAKOTA

Changes at State Hospital—Dr. Louis B. Baldwin, superintendent of the North Dakota Institution for the Insane, Milled Crofton, has been appointed superintendent of the State Hospital for the Insane of North Dakota, Jamestown, vice Dr. Dwight S. Moore.

Society Meeting—The Shovonne Valley Medical Society held its annual meeting at Valley City and elected the following officers: President, Dr. Carl L. Linn; Secretary, vice president, Dr. Albert A. Lang; Sanborn; and secretary, treasurer, Dr. Willi C. Nolte, Duxey.

Smallpox.—Owing to the fact that occasional cases of small pox have been found in the towns around Grand Forks, and by reason of the risk involved of its spread at the breaking up of the lumber camps, the Grand Forks Board of Health has decided to insist on the state law requiring the vaccination of all children attending public schools.

OHIO

Public Policy and Legislation.—The state and auxiliary committees on public policy and legislation of the Ohio State Medical Association will hold a joint meeting May 22 at Columbus. The chief subjects to be discussed are "A Summary of Medical Legislation," Dr John W. Clemmer, Columbus, "Illegal and Fraudulent Practitioners," Dr Walter H. Snyder, Toledo, "Education of the Public as a Check to Evils of Venereal Diseases," Dr Benjamin R. McClellan, Xenia, "Medical Practice Legislation," Dr Charles A. L. Reed, Cincinnati, "Criminal Abortion," Dr Robert H. Grube, Xenia, "The Advertisement of Venereal Cures in Public Press," Dr David R. Silver, Sidney, "Proprietary Medical Legislation," Dr George H. Matson, Columbus, "The Public Health Service," Dr Walter W. Brand, Toledo, "Tuberculosis Legislation," Dr Charles C. Probst, Columbus, and "Medical Service in Public Institutions," Dr Gilbert E. Robbins, Chillicothe.

County Secretaries' Meeting.—The secretaries of seventy-five county medical societies of the state met at Columbus, April 25. Dr J. H. J. Upham, Columbus, was made temporary chairman, and Dr Charles J. Shepard, Columbus, temporary secretary. It was decided to hold another meeting at Cedar Point at the time of the meeting of the state association in August, and to effect a permanent organization. Among the papers read were the following: "Address of Welcome," Dr Frank Winders, Columbus, secretary of the Ohio State Medical Association, "The Relation of the Secretary to the Society and to the Profession," Dr Clyde E. Ford, Cleveland, secretary of the Cleveland Academy of Medicine and the Cuyahoga County Medical Society, "The Relation Between Local and District Societies," Dr Joseph S. Rardin, Portsmouth, "How the Secretary's Work May be Made Easier," Dr Carrie Chase Davis, Sandusky, secretary of the Erie County Medical Society, "My Plans for the Struggle," Dr Cornelia B. Kennedy, Findlay, secretary of the Hancock County Medical Society, "What Can a Secretary Do to Secure More Members?" Dr John B. Donaldson, Lorain, secretary of the Lorain County Medical Society. After luncheon which was served at the Neal House Dr Charles A. L. Reed, Cincinnati, spoke on medical legislation. Dr John B. Donaldson, Canonsburg, Pa., secretary of the Washington County (Pa.) Medical Society, spoke on "The Secretary and His Opportunity." Papers by Dr Hirschel Fisher, Lebanon, secretary of the Warren County Medical Society, on "How Can We Make Open Meetings More Successful?" Dr Horace Bonner Dayton, counselor for the second district on "The Social Factor in the Life of the Successful Physician," Dr O. M. Wiseman, Zanesville, secretary of the Muskingum County Medical Society, on "Our New Doctors," Dr R. H. Grubb, Xenia, secretary of the Green County Medical Society, on "How Does Postgraduate Study Help the County Medical Society?" and Dr N. Worth Brown, Toledo, secretary of the Toledo Lucas Academy of Medicine, on "How Does Postgraduate Work Help the City Medical Society?" comprised the afternoon's program. The large attendance and the evident value of the meeting proved most encouraging and it is probable that meetings for conference and mutual helpfulness will be held regularly.

PENNSYLVANIA.

Consumptive Camps.—The senate approved the appropriation of \$600,000 for sanatoria for indigent persons infected with incipient tuberculosis.

Anti-Vaccination Bill.—A bill to permit the admission to schools of pupils whose physical condition makes vaccination dangerous to their health was passed finally by the senate May 7.

Regulation of Marriage.—The senate passed the bill to prohibit marriage on the authority of licenses issued more than 30 days prior to such ceremony, providing that no marriage licenses shall be issued unless the parties shall first give certain information and requiring this information to be certified to the department of health.

Free Patients Barred.—It is stated that the White Haven Hospital for Consumptives will receive no more free cases after June 1. The cause is said to be due to want of funds and because the state appropriations during the past several years have not been sufficient to allow the institution to continue to receive the great number of poor patients applying for admission.

For Hospital Investigation.—The House of Representatives, May 6, adopted a joint resolution providing \$20,000 for an investigation of the expenditures by asylums, hospitals and all semi public institutions which receive state aid. The commission will report at the next session, suggesting new laws to govern the appropriations.

Appropriations for Hospitals.—The following appropriations were presented to the senate and approved by the house: Jefferson Hospital, Philadelphia, \$300,000, Douglass Hospital, Philadelphia, \$32,000, Bellevue Hospital, \$15,000, Warren State Insane Hospital, \$250,000, Harrisburg Hospital, \$53,500, Ridgway Hospital, \$15,000, Philadelphia Living in Charity Hospital, \$20,000, Philadelphia Home for Aged Veterans, \$23,000, Wills Eye Hospital, \$70,000, Garrettson Hospital, \$42,500, Philadelphia Sanitarium, \$5,000, Philadelphia Maternity Hospital, \$6,000, St. Mary's Hospital, \$30,000, St. Vincent's Home, \$10,000, West Philadelphia Hospital for Women, \$10,000, Philadelphia Gynecical Hospital, \$25,000, Kensington Hospital, \$15,000, St. Christopher's Hospital, \$20,000, Philadelphia Home for Incurables, \$45,000, Coatesville Hospital, \$17,500, Easton Hospital, \$30,000, State Hospital, Hazelton, \$45,500, Williamsport Hospital, \$65,000, Lebanon Hospital, \$16,502, Chester County Hospital, West Chester, \$16,000, State Hospital, Scranton, \$166,878 74, Phoenixville Hospital, \$15,000, York Hospital, \$20,000, Norristown Hospital, \$32,000 and Danville Hospital for the Insane, \$429,300.—By the will of the late Rev. Samuel A. Heilner, the Methodist Hospital Philadelphia, will receive \$10,000.

Philadelphia

Interne Examination.—An examination for positions as resident physicians in the Philadelphia Hospital will be held June 4. The examination is open to any medical graduate.

Jefferson Alumni Announcement.—The General Alumni Association of Jefferson Medical College announces a meeting at Atlantic City during the session of the American Medical Association. The annual business meeting will be held in the college June 1, and the annual banquet will be held in the Bellevue Stratford the same day.

The New Jefferson Medical College Hospital.—The dedicatory exercises of the new Jefferson Medical College Hospital, which has just been completed at a cost of \$1,500,000, will be held June 7. A picture of the building appeared in *THE JOURNAL*, May 4. Addresses will be delivered by Hon. William Potter, president of the board of trustees, by Dr. William H. Welch, professor of pathology in Johns Hopkins University, representing medical science, and by Dr. J. Chalmers Da Costa, professor of surgery in Jefferson Medical College, representing the faculty and alumni.

Gifts and Bequests.—Mr. Stephen Green, ex president of the board of trustees of the Methodist Hospital, has presented a building to that institution to be used as an isolation ward. The building is to be one story high, of brick and terra cotta and will be erected at a cost of \$6,000.—By the will of the late John Simmons the Methodist Hospital will receive \$5,000 for a free bed to be known as the "John Simmons Bed."—In memory of the late Theodore Spencer, vice president and general manager of the Bell Telephone Company, the employees of the company have endowed a free bed in the Pennsylvania Hospital.

Philadelphia to Entertain.—Intending visitors to the meeting of the American Medical Association at Atlantic City will benefit by many events planned to occur in Philadelphia before and after the Atlantic City meeting. Specially arranged series of clinics will be given at all of the teaching institutions, hospitals, etc., on June 3, 7, 8 and 12. The dedicatory exercises of the new Jefferson Hospital will be held June 7. The Medical Club of Philadelphia will entertain the retiring and newly elected presidents of the American Medical Association June 7 at a reception at the Bellevue Stratford.

Personal.—Dr. and Mrs. Wharton Sinkler sailed for Europe May 11.—Dr. William S. Newcomet has been elected president of the Oncologic Hospital, and Dr. Charles W. Sheppard was elected assistant physician to the same institution.—Dr. Charles Nassau has been appointed demonstrator of applied anatomy in Jefferson Medical College, and Dr. Hoffmann assistant demonstrator.—Dr. Albert E. Roussel has been honored by the French government with the decoration of the purple ribbon, which confers on the holder the honorary title "Officier de l'Académie."—Dr. George B. McClellan, professor of applied anatomy in Jefferson Medical College, was presented with a silver case by his students, May 8.

Bureau of Health Report—The report of the bureau of health for March shows that in the division of medical inspection 3,720 inspections were made, excluding schools, 615 fumigations were ordered, and 63 cases were examined for special diagnosis. The medical inspectors made a total of 5,301 visits to the different schools, and of this number 683 children were excluded from school. The inspectors collected 371 cultures, made 130 injections of antitoxin and performed 231 vaccinations. During the month 2,613 deaths and 2,392 births were reported. In the division of milk inspection 7,496 examinations were made, which comprised 159,755 quarts of milk, 834 of which were condemned. The report of the bacteriologic laboratory of the bureau shows that 1,653 diphtheria cultures and 560 specimens of suspected typhoid blood were examined, 865 bacteriologic examinations of milk and 147 bacteriologic examinations of sputum were made, 6 disinfection tests were performed and 2,700,500 units of antitoxin were distributed throughout the city.

Treated the Sick for 156 Years—On May 6 the contributors of the Pennsylvania Hospital held their one hundred and fifty-sixth annual meeting. The Pennsylvania Hospital was the first hospital established in America, and at a period when there were but few such establishments in England or continental Europe. Public opinion had been prepared for it by Benjamin Franklin who had written in his newspaper of its utility and desirability, and whose connection with the assembly enabled him to secure the passage of an appropriation of £2,000 for its foundation, conditioned on the movers securing a like amount. The plan for the hospital was drawn in London. Franklin was not himself the projector of the hospital. It had its origin in the mind of Dr. Thomas Bond. The annual report of the hospital shows that the number of patients admitted to the receiving wards during the year was 27,660, of whom 4,100 were transferred to the wards. The report of the out-patient department shows that 10,861 surgical cases were treated, 2,345 medical, 2,015 eye, 612 ear, 1,216 nose and throat, 424 gynecologic, 47 mental and nervous, 1,388 dermatologic in all 18,908. The total number of visits in the out-patient department was 60,631. The total expenses of the hospital for the sick and injured were \$152,124.47, or \$9,339.01 more than the expenditures of last year.

Pathological Society Semi-Centennial—The Pathological Society of Philadelphia commemorated the fiftieth anniversary of its founding May 10 and 11. The exhibition meetings began May 9 and continued until May 11. The formal exercises were opened by the president Dr. W. M. Late Coplin, at 10 a. m. May 10 when the society went into scientific session a report of which will be found in this issue under *Society Proceedings*, page 1709. At 7 p. m. a dinner, at which 157 covers were laid, was held in the Clover room of the Bellevue Stratford. The following committee had this dinner in charge: Drs. W. M. Late Coplin, Allen J. Smith, Joseph McFarland, Warfield T. Longcope, Courtland Y. White, Alfred Stengel, David L. Edsall, David Riesman, J. Dutton Steele and Albert P. Francine. Dr. George E. de Schweinitz of the University of Pennsylvania was toastmaster and called on the following to answer to the toasts of the evening: Dr. S. Weir Mitchell, Philadelphia, "The Founders of the Pathological Society," Dr. William H. Welch, Johns Hopkins University, "The Pathologic Era in Medicine," Dr. J. Collins Warren, Harvard Medical School, "The Surgeon and Pathologist," Dr. Simon Flexner, Rockefeller Institute, "Experimental Pathology," and Dr. Alfred Stengel, University of Pennsylvania, "The Pathological Society of Philadelphia." Informal toasts were responded to by Dr. Reginald H. Fitz, Harvard University; Dr. George Dock, University of Michigan; Dr. Frank Billings, University of Chicago; Dr. Alonzo F. Taylor, University of California; and Dr. Abraham Jacobi of New York. The guests of the society were: Drs. Reginald H. Fitz, president Congress of Physicians and Surgeons, professor of medicine of Harvard University; J. Collins Warren, Harvard University; Abraham Jacobi, New York; Simon Flexner, Rockefeller Institute; George Dock, University of Michigan; William H. Welch, Johns Hopkins University; Frank Billings, University of Chicago; Fred C. Novy, University of Michigan; Frank B. Mallory, Harvard University; Alexander Blackader, Montreal, Canada; Woods Hutchinson, Redlands, Cal.; James Iwing, Cornell University; Alonzo F. Taylor, University of California; Philip K. Brown, University of California; Richard M. Pearce, Albany, N. Y.; Milton I. Rosenau, Marine Hospital, Washington, D. C.; James R. Hunt, New York City; H. M. Christian, Harvard Medical School; Robert B. Greenough, Boston; Herbert C. Moffitt, University of California; J. Collins Warren, Jr., Boston; Philip Marvel, Atlantic City, N. J.; Richard O. Reeve, Toronto; Edmond Souchon, Louisiana; and Joseph H. Pratt, Boston.

SOUTH DAKOTA.

Personal—Dr. F. Arthur Van Buren, Lead, has resigned his position in the Home State Hospital.—Dr. Clark B. Alford, Huron, has retired from practice on account of failing health.

Sanitarium Established—A number of the physicians of the Black Hills have formed an organization for conducting a sanatorium and hospital at Hot Springs. A residence with 26 rooms has been leased, which will be converted into a sanatorium and properly equipped.

State Board Appointments—The governor has appointed Dr. William H. Lane, Miller, a member of the State Board of Health, and Drs. Frederick W. Frevburg, Mitchell, Joseph M. Walsh, Fort Pierre, and Leslie G. Hill, Watertown, members of the State Board of Medical Examiners.

District Society Meeting—At a meeting of the Fifth Council District Medical Society, held at Madison, Dr. Lars J. Hauge, Howard, was elected president, Dr. Frederick O. Kap, Winfred, vice president, Dr. Henry H. Freudenfeld, Madison, secretary treasurer, and Dr. Alonzo E. Clough, Madison, censor.

TENNESSEE

Commencement—At the annual commencement exercises of Chattanooga Medical College, Medical Department Grant University, April 29, Hon. Henry Clay Evans delivered the address of the evening, Dr. G. Manning Ellis spoke on behalf of the faculty, and Dr. S. Holtzclaw delivered the valedictory.

Charter Asked For—The Baptist Memorial Sanitarium Association, Memphis, has applied for a charter. The organizers wish to erect a building to cost \$250,000, directly east of the College of Physicians and Surgeons, to be used as a hospital building. The site for the hospital was donated by the college, which has also pledged \$25,000 for the equipment and maintenance of the hospital. In return the college is to have exclusive clinical facilities at the hospital.

VERMONT

Analyses at State Laboratory—The pure food law has caused a great increase in the samples of food, milk and liquors sent to the state laboratory at Burlington for analysis. More than 1,000 samples were examined during March.

Personal—Dr. Edward O. Whipple, Danby, is still in active practice although in his eighty-seventh year.—Dr. Clarence F. Ball has been appointed health officer of Rutland, vice Dr. R. Halford Miner, resigned.—Dr. Everett F. Potter has resigned as selectman of North Pownall.—Dr. Joseph W. Jackson, health officer of Barre, has resigned.

WASHINGTON

Elections—The Asotin County Medical Association at its annual meeting, held in Clarkston, elected the following officers: President, Dr. Lafayette Woodruff, Asotin; vice president, Dr. Paul W. Johnson, Clarkston; secretary, Dr. Isaiah U. Temple, Clarkston; treasurer, Dr. Stephen D. Bragueau, Asotin, and censors, Dr. David H. Ransom, Clarkston, John S. McElvain, Anatone, and Henry C. Fulton, Asotin.

Hospital Notes—The Sisters of Providence, Seattle, are about to erect a new hospital, to cost not less than \$300,000.—Drs. Adelbert J. McIntyre, Franklin L. Carr and I. McDonald are about to build a hospital at Hoquiam, to cost \$30,000.—Old Fort Spokane is to be transformed into a sanitarium for Indian children from the Spokane and Colville reservations as well as the reservations in eastern Washington and northern Idaho.—The trustees of the Children's Orthopedic Hospital, Seattle, who have already \$20,000 in the treasury toward the hospital, have decided to increase the cost of the building to \$50,000. A site for the institution has been donated by Samuel L. Crawford.

WISCONSIN

Smallpox—Smallpox of mild type is reported to be epidemic at Grand Rapids.—The public schools of Royalton, which had been closed two weeks ago on account of the prevalence of smallpox, were reopened April 18.

Personal—Dr. W. C. Winters has been appointed pension examining surgeon at August.—Dr. Fred M. Adams resigned.—Dr. Wendell " " elected mayor of La Crosse.—Dr. John " elected health officer of Manitowish.

Medical College U
tees on education.

" the
" the

measure providing an annual appropriation of \$50,000 for the establishment of a college of medicine at the University of Wisconsin, was discussed. The president of the university and the chairman of the State Board of Health declared that the University of Wisconsin is the only state university of importance that does not provide adequately for students who desire to study medicine.

GENERAL

Honors to Americans—The Russian Surgical Society, at its twenty-fifth anniversary meeting in St. Petersburg, May 9, elected Dr. Nicholas Senn, Chicago, and Dr. William H. Watson, Utica, N. Y., honorary members.

Raise Money for Hospital—The society women of Monterrey, Mexico, cleared \$8,000 in the fête given April 27 and 28 in the Porfirio Diaz Alameda. This sum will be given to support the San Vicente De Paolo Hospital.

Grand Island Surgeons Meet—At the annual meeting of the Society of Surgeons of the St. Joseph & Grand Island Railway, held in St. Joseph, Mo., April 18, Dr. B. Pearne Hatch, Beatrice, Kan., was elected president, Dr. George A. Birdsall, Alexandria, Neb., vice president, and Dr. Luther A. Todd, St. Joseph, Mo., secretary and treasurer. The next meeting will be held in St. Joseph in June, 1908.

Hospital Car—The Erie Railroad Company has put in service a hospital car to be used primarily for employes of the railroad in case of accident, and also as an adjunct to the equipment of wrecking trains. The car is 40 feet long, fitted with six wheel trucks, made almost entirely of steel, with a ward room accommodating 11 patients and furnished with lavatory and toilet. It also has an operating room thoroughly equipped.

Warning Concerning Magazine Solicitor—A Boston correspondent states that a number of physicians in his vicinity have been victimized by a proposition to supply the London Graphic for their reception rooms for the cost of the postage viz. \$1.04. When none of the copies were forthcoming our correspondent wrote to the alleged headquarters in New York City (International Foreign News Co., Washington Square) but his letter was returned to him undelivered.

Navy Medical Bulletin—The Navy Department has begun the publication of a quarterly, known as the *United States Naval Medical Bulletin*, issued for the information of the naval department of the service. It is limited to professional matters as observed by medical officers at shore stations and on board ship in every part of the world, and principally to the physical welfare of the navy personnel. The first issue appeared in April and contains special articles on "The Gross Pathology of Samoa, with Comments on Sanitary Features and Treatment" by P. A. Surgeon A. M. Fauntleroy, "A Preliminary Note on Flagellates," and a report of a case of "Tropical Febrile Splenomegaly," by Assistant Surgeon H. W. Smith, also clinical notes and comments on medical progress and current events.

Smallpox in the Philippines—Dr. V. C. Heiser, chief quarantine officer, reports that a few sporadic cases of smallpox continue to occur in Manila. An investigation of the cases usually shows that the infection was contracted in one of the provinces in which the population has not yet been completely vaccinated. The crew and passengers detained in quarantine at the Mariveles quarantine station, on account of a patient with smallpox, who was removed from the steamer *Ban Yel* on which they were traveling were held for 14 days, being released Feb. 22, 1907. As a precautionary measure all the troops were vaccinated as well as all persons in the immediate vicinity of the place in which the troops were stationed. So far no case which could be diagnosed as true smallpox has made its appearance.

Special Quarantine Regulations for Fruit Vessels—As a consequence to vessels engaged in the fruit trade provision has been made in the quarantine regulations according to the reports of the U. S. Public Health Service, to obviate the injurious detention of perishable cargoes in the southern ports. While these regulations are stringent they do not impose an embargo on the fruit traffic. The success of the new regulations is dependent on the reliability of the information as to health conditions at the various ports from which the vessels come. The government therefore reserves the right when dissatisfied with the information furnished, to recall from such a port the medical officer there detailed. In such a case the special certificates required could not be issued and the vessel on arrival would have to be subject to the general quarantine regulations.

Health of the Isthmus for March—Col. W. C. Gorgas, chief sanitary officer, reports that the general health of the Isthmus was excellent during March. The number of men constantly sick among the employes has decreased steadily since August, 1906, the rate for March being 19.40. This, says Gorgas, is as low as they can ever hope to get it. Among the 4,600 Americans whites there were only two deaths. Among the American women and children living in commission quarters there were no deaths and very little sickness of any kind. Pneumonia was the disease which caused the greatest mortality, during the month it caused 53 deaths, all among the negro employes. The negroes showed the highest mortality and the American whites the smallest. No case of yellow fever has occurred in the Isthmus since May, 1906. There were no quarantinable diseases during March.

Academy of Medicine Election—The Academy of Medicine, formed at Springfield, Mass., with over 200 charter members from western Massachusetts, Vermont and New Hampshire, which we mentioned on page 428, Feb. 2, 1907, has elected the following officers: Dr. Walter A. Smith, Springfield, president, Drs. John A. Houston, Northampton, and Ralph H. Seelye, Springfield, vice presidents, Dr. Joel I. Butler, Springfield, secretary, Dr. Harvey W. Van Allen, Springfield, treasurer, Drs. Oscar W. Roberts, Springfield, Oliver W. Cobb, Frederick W. Chapin, Springfield, Edgar H. Guild, Springfield, and Walter R. Weiser, Springfield, board of directors, and Drs. Theodore S. Bacon, Springfield, James B. Atwater, Westfield, Louis H. Clark, Holyoke, and Frederick B. Sweet, Springfield, censors. The Academy expects to establish a graduate course in medicine and to furnish a home for medical clubs and societies.

Seeking National Health Department—The committee of one hundred appointed by the American Association for the Advancement of Science to further the establishment of a national department of health met at New York City, April 18, and organized by the adoption of rules, the election of officers, and the appointment of an executive committee. Prof. Irving Fisher, New Haven, presided as the temporary chairman and was subsequently elected president. Ten vice presidents were elected as follows: President, Charles N. Flot, Harvard University; Felix Adler, New York; Dr. William H. Welch, Baltimore; Rev. Lyman Abbott, New York; President James B. Angell, University of Michigan; Miss Jane Addams, Chicago; Hon. Joseph H. Choate, New York; Rt. Rev. John Ireland, St. Paul; Hon. Ben B. Lindsey, Denver; Hon. John D. Long, Boston; Mr. Chumpe S. Andrews was elected secretary. Prof. Irving Fisher, Dr. Thomas Darlington, Prof. J. P. Norton, Dr. John S. Fulton, Dr. Richard C. Newton, Prof. F. F. Westbrook, and Champe S. Andrews were elected executive committee to further the establishment of a national department of health. The committee on publicity is to spread information through the public press and otherwise. At a meeting of the executive committee Dr. Charles A. L. Reed told of the work done by the American Medical Association in advocacy of a national department of health. He urged that a department not a bureau, should be sought. The Council on Medical Legislation of the American Medical Association is in communication with a physician in each county in the United States, who is laboring in the interest of this work and has an index of the men in each county who are active in politics. As secretary of this council he offered these resources to the executive committee. The official office of the secretary of the committee of one hundred was established in the office of the Public Health Defense League at 105 East Twenty-second Street, New York.

CANADA

Hospital News—The new hospital at Saskatoon, Sask., is to be conducted by the Grey nuns.—Much success is attending the endeavor to establish in various hospitals in Canada memorial cots to the memory of the late Lady Grenfell, daughter of Governor General and Lady Grey.

New Medical Laboratory for Queen's University—Lieut. Gov. Mortimer Clark of the province of Ontario, will lay the corner stone of the new medical laboratory of Queen's University, Kingston, Ont., April 28. The Ontario government contributed \$50,000 toward the erection of this new medical building.

FOREIGN

Smallpox in China—Acting Assistant Surgeon Ransom reports that smallpox is prevalent in Shanghai, Nanking and Tientsin. The figures obtainable, he states, can only be taken as an index of the prevalence of the disease and represent but a small percentage of the number actually suffering from smallpox.

Joint Meetings of Medical and Legal Societies—At a number of places in Germany, physicians have taken the initiative and summoned a joint conference of lawyers and physicians to discuss various questions of forensic medicine, especially criminal psychology. Arrangements are being made to hold these joint conferences quarterly, as they are proving extremely instructive and valuable.

Gratitude for Private Instruction.—A Bienfait of Liege, Belgium, found time outside of his duties as general practitioner, neurologist and secretary of the *Gaz Méd Belge*, to deliver a course of lectures on the pathology of the nervous system. The thirty or more physicians who attended the lectures descended on his house one evening and presented him with an up to date Roentgen equipment as a token of their appreciation of his kindness.

Bequest for Convalescent Home—The great benefits of a home for patients during convalescence are appreciated by physicians more than any one else, and several physicians have left money for that purpose in their wills in the last few years in various countries. The latest is Dr Buhl of Heidelberg, whose will bequeaths his property to the university of Heidelberg, subject to a life pension for his wife. After her death, about \$75,000 becomes available for the construction of the home and about \$50,000 for its maintenance.

International Anti Alcohol Congress—The last anti alcohol congress was held at Budapest in 1905. The next will convene at Stockholm, July 28 to Aug 3, 1907, the eleventh international gathering, to discuss the evils of alcohol. Communications for the congress are to be sent to Prof C Wallis, Tegnergatan 2, Stockholm. The crown prince will preside, and a large number of communications have already been received, including those on "Alcohol and Responsibility," "The Burdens Imposed on the Community by Alcohol," "Alcohol in the Rural Districts," "Alcohol in Lapland," etc.

Organization of the Profession in Bohemia.—THE JOURNAL has already referred to the recent organization in German Bohemia of a society with the same aims and purposes as the German *Leipziger Verband*. It is doing good work and has accomplished valuable results already in its brief span of existence. A national election is impending, and the society has issued a circular which has been sent to every physician in the country acquainting him with matters of importance to the profession depending on his vote and influence. By this concerted action it is hoped that legislation promoting public health and the welfare of the profession can be secured.

Glasgow Maternity Hospital.—Like almost every other hospital in Glasgow, Scotland, the Maternity Hospital is appealing to the public for funds to complete the additional buildings in course of erection. This hospital was originally started in 1834 and the present building was erected in 1840. For a number of years both patients and students have been crowded. According to the *Lancet*, the directors believe that the buildings now being constructed will enable them to meet the pressure on their present inadequate accommodation for patients and at the same time to provide a school thoroughly equipped for the teaching of practical obstetrics and gynecology. Toward the cost of the new buildings and equipment \$200,000 has been subscribed and \$175,000 more is required.

Surgical Congress of the Northland.—The Nordisk Kirurgisk Forening will hold its annual congress at Christiania, Aug 7-10, 1907. The subjects appointed for discussion are "Resection of the Large Intestine," "Indications, Technique and Results of Prostatectomy," and "Treatment of Inflammatory Affections of the Adnexa." Bloch and Borelius will open the discussion on the first topic, and A Gunderson of La Crosse, Wis. will deliver the address on the second subject, while the third will be introduced by Engstrom and Kaarsberg. Further particulars can be learned from the president, K Jervell, Christiania, or the secretary, Dr Tscherning, Copenhagen. Borchgrevink announces a communication on the subject of "Ambulant Tension Treatment of Fractures of the Upper Extremities."

Consultations for Infants in Every French Town.—The French minister of the interior has notified all the prefects throughout France that they must organize a "mothers' dispensary" or consultation for infants, similar to the one founded by Budin in Paris which has been frequently mentioned in these columns. Budin devoted much time and energy to the extension of the system of "nursing consultations" and the sickness and death rate among infants was materially reduced wherever they are introduced. Since his recent death testimony in this line has been accumulating more and more until now the French authorities have decreed the universal adoption of the system. Budin actually gave his life for the cause as he died of pneumonia contracted on a trip to a neighboring city to lecture on the subject.

The Cocain Evil in Calcutta.—The Indian correspondent of the *Lancet* states that the cocaine habit has obtained a great hold on the lower classes in India. The *Lancet's* correspondent states that this is the more remarkable, as but a small part of the population drinks tea or coffee. In 1900 the sale of cocaine was limited to medicinal purposes, and only certain persons were granted licenses to sell it. In 1902 the possession of more than 60 grains was made illegal. Notwithstanding the strict rules against importation the drug is said to find its way into the country from Germany through unscrupulous dealers in the native states and in the little strips of foreign territory which remain in India. It is said that the principal trade is through Delhi. The profit is large and the cocaine is never sold pure, being mixed with phenacetin or other drugs.

Bier Succeeds von Bergmann in Chair of Surgery at Berlin.—A cable dispatch states that August Bier has been appointed professor of surgery in the University of Berlin, to succeed the late von Bergmann. It has been known for some weeks that the choice wavered between Bier and von Eiselsberg of Vienna. The latter was called to Berlin some years ago, but declined, as his mother was a loyal Viennese, and he did not wish to leave her and she would not leave Vienna. She has since died. THE JOURNAL published April 25, 1906, page 1299, a portrait of Bier and a brief sketch of his career. The cable dispatch adds that Bier's summary dismissal of von Bergmann's assistants as his first official action has aroused much unfavorable comment. He is only 40 at present, but has occupied in turn the university chairs of surgery at Kiel, Greifswald and Bonn.

Physicians Win in Long Conflict at Gera.—One of the first cases in which the German *Leipziger Verband* was called on for its services after it was organized was at Gera. The medical officers of a certain sickness insurance society protested against the addition to the medical force of a non qualified "nature healer," directly contrary to their contract with the society. As the superintendent of the society paid no attention to their protests the physicians resigned, and the *Leipziger Verband* championed their cause. The society held back half of the last quarter's payments due the medical officers, and the latter sued for the amount due them. The case after four years has finally been decided in favor of the physicians. The judge stated that the society had acted contrary to its contract—not the medical officers—and ordered the society to pay the amount still due the physicians, with interest to date, and also imposed the costs of the suit on the society.

International Congress on Stomatology.—An international congress of stomatology has been organized to meet at Paris Aug 6 and 7, 1907. The executive committee includes prominent dentists from various countries and an exhibition of appliances and objects of historical and educational interest will be held in connection. The official language of the congress is French but English and German will also be admitted if the article presented is followed by a brief summary in French. It is stated also that Esperanto will be allowed in the discussions. The international congress is to be preceded by a national French Congress of Stomatology, arranged in honor of the twentieth anniversary of the French Société de Stomatologie. The chief aim of this national congress it is said is to demonstrate and emphasize that a general medical education is indispensable for the practice of stomatology, as well as for laryngology and ophthalmology. Stomatology is as much a medical and surgical specialty as these other branches of medicine. Further details can be obtained from the secretary M Chompret 182 Rue de Rivoli Paris or from Dr Eugene S Talbot 103 State Street Chicago.

Alliance for Social Hygiene.—The *Alianza de Higiene Social* is a newly organized society in the Argentine Republic whose aim is to coordinate and promote all efforts in favor of public health and hygiene. The official program includes measures to combat "averia" (the newly coined Spanish term for venereal disease similar to the French "avarie") tuberculosis alcoholism malaria and infantile mortality to promote the care of child life in every way to improve the dwelling places and food of the poor to promote physical training and to organize centers for the education and protection of the public with exhibitions and permanent museums of everything relating to puericulture hygiene etc. The society also intends to use its influence for the adoption of compulsory insurance against sickness accidents and old age. F P Coni is the leading spirit in the movement and is making every effort that the society may be able to present a fine showing of tangible results when the world is invited to help the republic celebrate in 1910 the anniversary of the independence of Argentina. The *Semana Medica* for March 21 contains his address on the

subject presented at the Third Latin American Medical Congress recently held at Montevideo. Comi was the president of the second congress.

A Representative Board of Health.—The national board of health for the grand duchy of Baden has recently been enlarged to make it more representative. It has hitherto consisted of representatives of the medical faculties of the two universities, the president of the national medical society and several members appointed by the national authorities. The additional members now to be added are representatives from the departments in charge of the water supply and roads, the presidents of the university institutes of hygiene and the technical college at Karlsruhe, three members instead of one to be appointed as representatives of the medical profession, and one each from the dental, veterinarian and apothecaries' national associations. Besides these the organized employers of labor and also the wage earners are to have each a representative. The members are elected for a four year term and serve without remuneration, except that mileage and \$3 a day are allowed to those who do not live in the city where the meetings are held. The *Deutsche med. Wochschr.* adds to the above that the minister of the interior is *ex officio* president of the board, and he can invite expert talent from outside at any time to discuss questions that may arise.

Antiquackery Legislation Adopted in Germany.—The German authorities are on the point of adopting a decree applying throughout the empire certain regulations requiring that all persons—not registered physicians—who make a practice of treating the sick, must notify the police authorities when they locate in a place, and must give information in regard to their "practice," and must keep a set of books. They are forbidden to use "distant treatment," to treat contagious diseases, especially venereal diseases, and to use narcotics, hypnosis, suggestion, etc. The right to practice can be refused to persons who have previously been convicted of misdemeanors or crimes, or have been deprived of their civil rights for any cause. The right to practice can also be withdrawn at any time for the same reasons or for injury from their practices. Penalties up to \$375 and imprisonment can be enforced. Our German exchanges state that it is a pity that the regulations do not entirely forbid the treating of the sick by unqualified persons, but even as proposed, they represent great progress in the antiquackery movement. The question of "secret medicines" is next to be taken up, and a bill similar to the regulations in force in Austria is now being discussed which prohibits public advertising of such remedies and the importation of certain "secret remedies."

Cancer Suit Decided.—THE JOURNAL mentioned at the time the suit brought against the firm of E. Merck by A. Adamkiewicz, formerly professor at Cracow, inventor of cancerin, a remedy for cancer. He signed a contract with the Merck firm for the production, advertising and sale of the remedy, the contract to run for twenty five years, with the proviso that if the firm lost money by the deal they could withdraw from the contract at the end of five years. This they did in 1896, when Adamkiewicz at once brought suit for \$60,000 damages, the penalty for non fulfillment of contract, claiming that the firm had not fulfilled its contract, as it had failed to advertise and push the remedy in such a way as to bring it duly before the public. The Merck firm stated that it had lost money on the contract and that it had been deceived in respect to the curative value of the remedy. Professors von Eiselsberg and von Neusser testified that cancerin is merely a preparation of neurin, and that the after history of cases published by Adamkiewicz as "cures of cancer" showed that the remedy had not materially retarded the fatal progress of the disease. It was first put out as a secret remedy, and Adamkiewicz's methods of procedure led to his being dropped from the rolls of the Vienna Medical Society. The judge promptly decided in favor of Merck.

Congress of German Orthopedic Society.—The sixth annual meeting of this society was held at Berlin April 2, with Bardenheuer in the chair. The remote results of plastic operations on the tendons was one of the topics presented by various speakers. Hoffa exhibited a number of patients to show the fine results when the operation on the tendons was preceded by careful and prolonged correction or over correction of the deformities. He prefers total to partial transplantation of the tendon and thinks that suture of the tendon to the periosteum gives sometimes a firmer hold and better results than suture of tendon to tendon. In the after treatment a plaster cast must be worn for at least 6 weeks and then a

splint, with massage and active gymnastics. If there is enough reliable muscular tissue on hand, permanently good results may be counted on. Schanz reported that plastic tendon operations on the quadriceps had given him exceptionally fine results. Vulpus stated that he had had better results from transplantation of tendon on tendon. Lorenz emphasized the necessity for prolonged preliminary treatment with overcorrection. This will show the muscles best adapted for transplantation. In quadriceps paralysis he has found that osteoclasis of the femur helped very much in overcoming the functional obstacle. Fat embolism after bloodless operations was discussed also. Some of the speakers warned against attempting to accomplish too much at a single sitting. It is much better to proceed gradually. Under the age of 14 the danger of fat embolism is comparatively slight, as the bone marrow contains very little fat. Vulpus, however, stated that he had had 2 fatal cases in children under 10. Lorenz remarked that the previous use of a wheeled chair, by inducing extreme atrophy of the bones, causes a predisposition to fat embolism and other complications. Bardenheuer expatiated on the benefits of extension and early active movements to prevent ankylosis of the adjacent joints in case of fracture of a long bone.

German Congress for Internal Medicine.—The twenty fifth German Congress for Internal Medicine met at Wiesbaden, April 15, and the silver jubilee was celebrated by the election of 15 honorary members and by an inaugural address from E. von Leyden, the founder of the Society for Internal Medicine and of the congresses. The first subject discussed was "Neuralgia and Its Treatment." Schultze referred to arteriosclerosis as an occasional source of severe neuralgia, and stated that in sixteen cases of rebellious neuralgia of the first branch of the trigeminal nerve he had found the frontal sinus diseased in six instances. He also mentioned that brachial neuralgia is sometimes observed in the initial stage of paralysis agitans. Physical measures, he said, are more effectual than drugs, although aconitin has sometimes given good results. In some cases massage does wonders, in others electricity, in others application of heat, and Bier's hot air massage. Bier has reported the cure by hot air massage of twelve out of twenty patients who had entered the hospital for operative treatment of neuralgia. The hot air massage was described recently in THE JOURNAL on page 653. In some cases Schultze has cured rebellious neuralgia with hot sand baths, Scottish douches, etc. He has abandoned operative stretching of the nerve, but finds orthopedic stretching sometimes useful. Schlösser reported the present status of the treatment of neuralgia by local injection of 70 or 80 per cent. alcohol. This induces degeneration of the nerve, and the segment involved is absorbed, although the neurilemma remains intact, the effect being a medicinal resection of the nerve. Later it regenerates from the periphery toward the center. He has thus operated on 202 patients with chronic neuralgia, injecting from 1 to 4 c.c. of alcohol. In case of sensory nerves he injects from 2 to 4 c.c. of alcohol at different points, trying to destroy the nerve over as large an extent as possible. With motor nerves the aim is to induce paresis, and small amounts are injected through the cannula left in place, repeating every five minutes until there is paresis. In 38 cases of sciatica recurrence was observed in 2 patients after 3 or 6 months, the others have been cured to date, permanent cure has resulted in 16 cases of occipital, 8 brachial, 1 intercostal and in 2 of lancinating neuralgia in patients with ataxia. In the 11 cases of facial clonus recurrence followed in 9, but 7 of the patients proved to be hysterics and treatment had been suspended as soon as the hysteria was diagnosed. In 123 cases of trigeminal neuralgia—bilateral in 2—the average duration of the cure has been a little over 10 months. He advocates this "chemical resection" of the nerve as worthy of trial before resorting to such a serious operation as removal of the Gasserian ganglion. (Previous communications on the subject were mentioned in THE JOURNAL, page 1243, of vol. xvi 1906.) Lange reported good results from his method of injecting from 50 to 150 c.c. of physiologic salt solution in treatment of sciatica. Patients thus treated should remain in bed for a time. Improvement follows the first injection, and the cure is sometimes complete by the end of the third day. Quincke confirmed his statements and added that experiments on the cadaver had shown that the injections act only on the sheath and not on the nerve, so the technic is simple and easy. Alexander prefers injection of 10 c.c. of Schleich solution, he ascribes the pain to a combination of neuralgia and a myopathy, the muscular affection being generally overlooked. Krause reported the removal of the Gasserian ganglion in 56 cases and stated that 48 of the patients are alive and free from recurrence to date, but 8

died during or in consequence of the operation. He has never observed regeneration of the nerve after this operation. Brieger stated that physical measures cure in about 80 per cent. Absolute repose should be enforced in the acute cases, in the chronic forms a course of baths and dietetic measures are useful. Hanau reported great benefit from dry cupping in acute sciatica, and Minkowski from spinal anesthesia. Large doses of methylene blue proved successful in curing infectious neuralgia in von Noorden's experience, especially after influenza. Treupel has found repeated cocainization of the nasal mucosa of great benefit in cases of trigeminal neuralgia, even when the accessory cavities seemed to be entirely sound. Gara asserted that unless the lowest lumbar vertebra is sensitive to pressure there can be no sciatica, as he has found this sign constant in genuine sciatica. Bäumlér called attention to the neuralgia due to venous stasis, cured by improving the heart action with digitalis or other heart tonic. His has had occasion to observe neuralgia evidently due to a family tendency, and best combated by dietetic measures. "Edema in Nephritis" was the second subject discussed, and von Noorden emphasized the necessity for discriminating in treating nephritic patients by suppressing salt chlorids in the diet. He had witnessed cases in which reduction of albumin and chlorids in the diet induced great debility while, on return to an ordinary diet, the patients rapidly regained their previous strength. Naegeli of Zurich stated that later experience has confirmed his previous assertions in regard to the prevalence of tuberculous lesions. He found tuberculous lesions in 97 per cent of 1,000 cadavers, as reported in 1900, and this same proportion has been maintained through all his subsequent investigations and for all classes of society. Homigmann related that at the convalescent home for Russian officers at Wiesbaden 20 patients with serious traumatic hysteria have been under treatment and 23 others with severe neurasthenia. He commented on the fact that there is no record of such traumatic neuroses among the officers after the wars of 1866 and 1870. The above summary is culled from the nearly 6 page report of the congress in the *Semaine Médicale* April 24—the first journal to appear with an account of the proceedings.

LONDON LETTER.

(From our Regular Correspondent)

LONDON, April 20, 1907

Enlargement of the Library of the College of Surgeons

The library of the Royal College of Surgeons, which is the largest medical library in Great Britain and the largest in Europe, with the exception of the library in Paris, has outgrown the space allotted to it. It now contains 100,000 publications, made up of 60,000 volumes and 40,000 pamphlets. It increases at the rate of 1,000 volumes a year. A large room has been added over the library, which in former years consisted of a suite of apartments occupied by a clerk who lived in the college, a custom no longer followed. This room will be principally devoted to works on public health and official government reports. Thus space has been obtained for another 10,000 volumes.

The Jacksonian Prize

The Jacksonian prize of the college for 1906 on "The Diagnosis and Treatment of Those Diseases and Morbid Growths of the Vertebral Column, Spinal Cord and Canal, Which Are Amenable to Surgical Operations," has been awarded to Mr. Donald Armour, F.R.C.S. The following subject has been chosen for 1908, "The Pathology and Treatment of Those Conditions of the Colon Which Are Relievable by Operative Measures." The subject for the next triennial prize is "The Histologic Anatomy of the Lymphatic and Hemo-lymphatic Glands More Especially with Reference to the Changes Which These Glands Undergo in Acute Infective Processes." Prof. William Wright will deliver three Hunterian lectures on "The Prehistoric and Early Historic Inhabitants of England," on May 6, 8 and 10.

Effective Organized Effort.

The method adopted largely at the instance of the British Medical Association of preventing poor law authorities, friendly societies and others who contract for medical services obtaining them at rates deemed inadequate is to form combinations of medical men in the various districts who decide that no one shall apply for an appointment of this kind which happens to be vacant. Warning notices are inserted in the medical journals asking physicians who being strangers may know nothing of the battle waged with these contracting bodies to communicate with the secretary of the local medical society before applying for the post. Sometimes, however, a physician declines to fall in with the com-

bination and takes a proscribed appointment. In the language of the trades unions, he is a "blackleg." His position with regard to his medical brethren is then far from enviable, and he may be treated with all the rigor which trades unions adopt toward non union workers. In a country district the guardians, who recently appointed Dr. Charlton to the post of medical officer of the workhouse, received a letter from the physicians of the district, who refused to apply for the appointment, as they considered the salary inadequate, stating that they refused absolutely to recognize Dr. Charlton professionally or in any way whatever, either by acting as his deputy or in cooperation with him over any patient. If in any case of emergency additional medical aid should be required by the guardians, the local physicians will not refuse to attend, provided the entire control of the case is for the time being placed in their hands independently of Dr. Charlton. In such cases they will charge such fees as they consider reasonable and adequate. The guardians decided to take no action in the matter, the chairman observing "Of course, if the doctors refuse to recognize Dr. Charlton, that is a matter of no concern whatever to us."

The Milk Supply

Public opinion and the government appear at last to be awakening to the perils of the milk supply. A committee of the National League for Physical Education has been formed by Sir Lauder Brunton. This committee has now formed a joint committee with the National Health Society, the Infants' Health Society, and the Liverpool Infants' Life Preservation Committee. The chairman is Sir Frederick Treves. The committee is composed of men chosen from among the experts on milk, including health officers. The object is to secure a universal supply of milk, pure, fresh from the cow and free from disease germs—"clean milk." An annual system of licenses to dairymen renewable only if their premises are kept in sanitary condition, is recommended. The corporations of the great cities such as Manchester, Liverpool and Sheffield, have already obtained special parliamentary powers to enable them to exclude from their districts the milk of cows suffering from tuberculous udders. Such milk can be sold elsewhere. It is proposed that such powers should be extended to the whole country.

VIENNA LETTER.

(From our Regular Correspondent)

VIENNA, April 24, 1907

Distant Treatment by Letter or Telephone

The Vienna "Aerztekammer" (Medical Council) in one of its recent meetings discussed the question of treating patients without seeing them. It has been brought to the knowledge of the council that in several instances physicians, not quick to have been asked by patients residing at a distance in the country for professional aid and these doctors had thought fit to prescribe for diseases, the symptoms of which they could not possibly have found out except by regular examination. The council is of the opinion that such a way of treating is not to be approved of since the art of the physician is founded on the consideration of the patient as an individual and the treating of symptoms instead of the disease will not add to the dignity of the profession. In a similar way, consultations by telephone, unless the patient be known to the doctor, should be discarded. The council has sent a circular to all members of the profession in Vienna informing them of the resolutions voted and it proposes to deal summarily with all members complained of in the future by fining them about \$100.

Scarcity of Hospital Beds

The enormous increase of infectious diseases in Vienna especially of influenza measles and scarlatina during the last few weeks has swamped the hospitals. The number of beds is usually sufficient for ordinary needs but hundreds of patients were seeking admission to the hospitals and had to be turned away. This condition of affairs was not allowed to last more than five days by the public and the press. The municipal authorities finally consented to open "emergency hospitals" especially for scarlet fever and diphtheria while non-infectious patients are tended at their homes by municipal doctors and nurses. This system has been in existence only a short time. It is called "Distriktskrankenpflege" and the expense hitherto has been borne by the municipality. In spite of the two new pediatric hospitals erected quite recently by private donations (the two buildings together can accommodate only 200 children) the scarcity of hospital beds is an undeniable fact. There are for 42,000 inhabitants only 42 beds available for nursing at least appealed public

Pharmacology

TYREE'S ANTISEPTIC POWDER

Discrepancies Between Facts and Claims—Unfortunate Attempts of Mr Tyree at Explanation

A report from the Council on Pharmacy and Chemistry on Tyree's Antiseptic Powder appeared in *THE JOURNAL*, Oct 20, 1906. This showed that the preparation, advertised as a "scientific combination of borate of sodium, alumen, carbolic acid, glycerin and the crystallized principles of thyme, eucalyptus, gaultheria and mentha, in the form of a powder," was essentially a mixture of boric acid and sulphate of zinc—approximately four fifths of the former to one fifth of the latter. "The carbolic acid, thyme, eucalyptus, wintergreen, etc., if present, are present only in sufficient amount to give the compound a satisfactory odor." As will be remembered, in the correspondence published at that time, Mr Tyree attempted to explain the discrepancies between his statements and the proven facts by intimating that he had recently changed the formula, and that it was his intention "on or about the first of February to state to the medical profession his reasons for changing the formula," and that the change had been made "a short time ago," at the suggestion of several prominent gentlemen. Since that time, through circulars and other advertisements, Mr Tyree has attempted to explain the matter in various ways. In his latest circular letter he seems to make a deliberate attempt to mislead our profession and to misrepresent facts to a degree that makes it almost impossible to believe that the circular came from a man who claims to be honorable.

First, however, we shall take this opportunity to publish some matter which we have had in reserve since the first exposé was made last October. When it was realized that Mr Tyree intended to defend himself by claiming that a change had recently been made in the powder, we took occasion to try to secure some of the preparation that had been on the market for a long time. In this we succeeded very well. From a Chicago druggist one package was bought which had been in the store at least since July, 1902—how much longer is not known. The druggist from whom the powder was obtained bought the drug store in July, 1902, and this powder was on hand at that time, none having been bought since. This particular powder was analyzed by a chemist, who found the composition practically the same as that given in the Council's report, this chemist estimating that it contained approximately 81 per cent boric acid and 14 per cent anhydrous zinc sulphate. Bearing in mind that for at least four years and ten months Tyree's Powder has been essentially the same as it is to day, this letter is very interesting. (The comments in brackets are, of course, ours.)

"J S TYREE,

"CHEMIST,

"WASHINGTON, D C

"April 16, 1907

"Dr _____,

"My Dear Sir—Doctors and medical publications of extreme and prejudicial minds often hold and express opinions in honor of faith, but like all critics, they are not always familiar with the conditions composing their opinions, and are often given to expressing them without complete knowledge of the true motives and facts in the case.

"If you will read an article that appeared in one of the medical weeklies some time ago [*THE JOURNAL* of the American Medical Association of course] and which has been copied by several of its offsprings [not many, we regret to say] relating to Tyree's Antiseptic Powder you will see that I had previously informed the editor as well as his council of investigators that at the suggestion of prominent physicians extensive clinical experimenting [sic] were being made with some slight [!!!] change in my powder the object being to develop and extend its usefulness in new lines. [It had already been recommended for about everything!] and at the same time

1 From the circular accompanying a package bought over a year ago we find the powder recommended for the following conditions: For Leucorrhœa, Gonorrhœa, Vaginitis, Pruritus, Ulcerated conditions of the mucous membrane, Scrofulous

make it more acceptable to the general run of the profession. I also notified this editor that these investigations would not be completed until the first of the present year, after which time these slight [!!!] changes in the formula of Tyree's Powder would be announced. [It is now the middle of May, when and where were the changes announced?]

"There is nothing new, startling or dangerous in such changes in formulas. The Pharmacopœias and national books of authority are continuously improving their formulas. It is the same with every preparation on the market. [Mr Tyree, as a nostrum maker, is in a position to know. His plea evidently is "I am no worse than others."] The apparent difficulty in my case is caused by my exceptional frankness. ["exceptional frankness" is good under the circumstances] with the profession in telling them [when and where?] about this improvement before I was ready to announce full details and particulars, or place my improved [sic] powder on the market. Yours very truly,

"J S TYREE"

For years Mr Tyree has been misleading physicians by making false statements regarding the composition of his powder, and regarding its value as a therapeutic agent. When exposed he tries to defend himself and his business by statements and excuses that are worthy of a schoolboy trying to get out of a bad scrape. We would respectfully suggest to him that he either take his wonderful powder off the market, or—which probably would amount to the same thing—tell the truth, and the whole truth, about it.

Tennessee Pure Food Law a Model.

The Tennessee Legislature has adopted the pure food bill introduced by Dr W B Marr and known as House Bill 141. The bill as adopted is an admirable one and can not but accomplish much good in the state. It is worthy of note by members of the profession interested in pure food bills in other states. A professional lobbyist, whose presence has been noted in other state capitals at the time that similar legislation was being considered, "happened" to drop into Nashville at the time that the bill was before the legislature. He announced that he was a philanthropist, and that his mission in life was to harmonize the medical profession and the various drug interests. "He had the effrontery," says our correspondent, "to ask for an interview with some of the leading physicians of Nashville and to announce that he would address a joint meeting of physicians and druggists." It appears that his efforts were mainly devoted to lobbying against the bill by attempting to bring personal influence to bear on various members of the legislature. Efforts to coerce the local druggists were also futile. Evidently not enjoying the atmosphere of Nashville, the genial philanthropist left before the bill came to a vote. He has doubtless "happened" to go to other state capitals, where pure drug bills are pending.

Regarding the bill itself

Section 1 provides that it shall be unlawful to manufacture, sell or give away any article of food or drugs which is adulterated or misbranded.

Section 2 defines drugs to include all medicines and preparations recognized by the United States Pharmacopœia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation or prevention of disease in either man or animals. Food is so defined as to include all articles used for food, drink, confectionery or condiment either mixture or compound.

Section 3 defines adulterations in a drug as any deviation from the standard of the United States Pharmacopœia or National Formulary or deviation from the professed standard and quality under which it is sold. Such adulterations are specified as follows:

Syphilitic and Varicose Ulcers for Spraying the Nose and Throat for Immediate deodorizing and disinfecting for prickly heat, poison oak, squamous eczema and other conditions of similar nature As a deodorant and prophylactic in dental work for disinfecting offensive cavities, for profuse and offensive perspiration, swelling, soreness and burning of the body and feet As a delightful toilet preparation after the bath and shaving.

2 Last January the national Food and Drugs Act went into effect. One of its provisions is that the label must not lie. This is not the exact verbiage but it means the same thing. So instead of repeating the old false statements the new label of Tyree's antiseptic powder contains nothing whatever about the composition. The law does not require that it should—unless the preparation contains certain specified drugs. Why is the formula omitted?

The presence of any ingredient deleterious or detrimental to health.

The presence of any substance which would reduce lower or injuriously affect the quality or strength of the article.

The substitution in any manner either in whole or in part of any other substance for the substance claimed.

The substitution of any valuable constituent in whole or in part or the addition of any matter whereby damage or inferiority is concealed or the addition of any poisonous or deleterious ingredient which may render it injurious to health or the presence of any filthy, decomposed or putrid animal or vegetable substance or any portion of an animal unfit for use or of any product of a diseased animal or one that has died otherwise than by slaughter.

Section 4 takes up the question of misbranding which is specified to be

1. Offering for sale any article under the name of another article.

2. Removing the original contents of a package in whole or in part and placing other matters therein or failing to state on the label the quantity or proportion of alcohol, morphin, opium, cocaine, heroin, alpha or beta eucalin, chloroform, cannabis indica, chloral hydrate, or acetanilid, or any derivative or preparation of any such substance. This provision does not apply to prescriptions of regularly licensed physicians, dentists and veterinary surgeons when filled for the individuals for whom written nor to such drugs as are regularly recognized in the United States Pharmacopoeia and sold under the brand by which they are recognized.

3. Misbranding in the case of food is defined as the imitation or offering for sale of an article under the distinct name of another article, the labeling or branding so as to deceive or mislead the purchaser or purporting that the article is a foreign product when it is not or where the contents as originally put up have been removed in whole or in part and other materials placed in such package or the failure to place on the package a label stating the proportion and quantity of any of the above named drugs. Contents must be stated on the outside of the package. The label must bear no statement design or device which is false or misleading in any particular. Preparations marked compound, imitation or blend may be sold providing the fact is stated on the label. A guarantee provision for the protection of the retail dealer similar to the section found in the national Food and Drugs Act is found in Section 5.

Section 6 defines the scope of the act and Section 7 provides for the appointment of a chemist of established reputation and ability who shall be the pure food and drug inspector and who shall establish an office and laboratory in Nashville.

It is noteworthy that this bill contains no exemption clause, such as the druggists in many states are endeavoring to introduce into a bill which is otherwise not objectionable. The exemption clause, however, practically nullifies the bill.

Members of the profession in Tennessee are to be congratulated on the fight which they have made and the victory which they have won. The Tennessee bill is one of the strongest and most praiseworthy which has yet been adopted by any state.

A Wide-Awake Medical Magazine Comments on Labordine

The report published in THE JOURNAL March 30 by the Council on Pharmacy and Chemistry on Labordine was republished in full in the May *Medical World*. Editor Taylor added the following trenchant comment:

"The profession should appreciate the above important service rendered by the national organization, the American Medical Association. We have not advertised labordine this year, and we will never admit it to our columns again. As soon as the Council on Pharmacy and Chemistry published its report on the other acetanilid mixtures (antikamnia, bromo-seltzer, etc.) *The World* immediately republished the same and it was the only journal besides THE JOURNAL of the American Medical Association which did so for a long time as most of the other journals, including many of the state society journals, carried the antikamnia advertisement. About a year after the report appeared most of the state society journals, under pressure, were induced to publish it. Let us see what journals, including state society journals, will suppress this report, for the sake of advertising patronage present or hoped for. It is strange how a fraud like this could exist for so long by means of the patronage of a learned profession and not be found out. It is the legitimate field of a national medical organization to make investigations like the above. It is a duty which belongs to a public organization of national scope rather than to private initiative."

Death from Taylor's Anti Headache Powders

Drs. M. J. Sanford and D. V. Van Wagman of Suffern, N. Y., writing independently of each other report the following case of poisoning from headache powders:

C. M. male aged 7 years, awoke in the morning complaining of headache. His mother gave him some Epsom salts and a cup of coffee. As he was no better at 9 o'clock she gave him one of "Taylor's Anti Headache Powder." The boy was given

another powder at 10 15 and another at 11 o'clock. Soon after taking the third powder the child complained of faintness and lay down. At 11 45 his lips and tongue became very blue, his face was yellowish and his eyes staring—protruding—and unseeing. He was put on a lounge and apparently went to sleep, as he snored. At 12 15 he commenced to jerk, twitch and scream. The convulsive movements became worse especially of the right side, and the boy died shortly before 1 o'clock, 10 minutes before a physician arrived.

On the box containing the powders and on the circular accompanying it the following is printed:

Taylor's Anti Headache Powders. Guaranteed Absolutely Harmless. Contains no Opium, Chloral, Cocaine, Antipyrine, Morphine, Phenacetine, Bromide or Other Injurious Substance.

Never known to fail in curing Billious Sick or Nervous Headache and Neuralgia in a few minutes.

Directions—Take one powder dry on the tongue and drink a little water. Repeat if not entirely relieved in twenty minutes.

None genuine unless Signed W. Scott Taylor.

The Taylor Drug and Chemical Co., Manufacturing Chemists—Laboratory—Trenton, N. J.

Dr. Van Wagman sent us a box of the powders, examination indicates that they contain as active constituents acetanilid approximately 30 per cent, and caffeine, approximately 2.5 per cent. Each powder of the specimen submitted weighs approximately 15 grains and, therefore, contains about 4½ grains.

Personal Liberty and "Patent Medicine"

Although a vast majority of newspaper proprietors still seem to have no regard for the harm they do by allowing fraudulent and misleading "patent medicine" advertisements to appear in their papers, more and more are coming out on the side of cleanliness. A few remarks on the subject of personal liberty in the *Detroit Civic News* work up to a climax that is worth quoting. After remarking that those citizens who are most strenuous for "personal liberty," meaning by that, liberty to make public nuisances of themselves, are likely to protest against "grody goodies" at the first approach of restrictive legislation, administration, or agitation, the editor goes on as follows:

"Personal liberty" may involve the right to drink liquor, but it does not involve the right to get drunk and beat one's family, make a spectacle of oneself on the public street or go off to a bawdy house on a carousel. "Personal liberty" may give one the right to smoke, but it does not give one the right to blow his smoke into another man's face, or to vitiate the atmosphere in a room where another man who does not like smoke polluted air, has a right to be. "Personal liberty" may give a man a right to cultivate 'art' in any way he sees fit, but it does not give him the right to make a public nuisance of himself or to post pictures in his windows or on the billboards to smite our eyes, and to school our children in the ways of vice and crime, whether we like it or not. "Personal liberty" may give people the right to corrupt their own bodies and fool with their own health, but it does not give quack doctors the right to issue circulars and newspapers to print advertisements full of base lies calculated to mislead the young and inexperienced into the notion that Nature's laws can be violated with impunity."

The Slaughter of the Innocents Continues

Dr. S. D. Barnes, Seattle, Wash., sends us an account of the death of twin babies which, he says, occurred from an overdose of Mrs. Winslow's Soothing Syrup.

On March 31 the children were found dead in the perambulator in which they had been put to sleep. Deputy Coroner Wiltse and Police Sergeant Bannick investigated the affair. At first they believed that the children had been smothered, but later were informed that they had been given a dose of soothing syrup before being put to bed the night before. The stomach contents were analyzed and the report of the analysts stated that small quantities of opium were found. The coroner decided that an inquest was unnecessary and signed the death certificate giving accidental poisoning as the cause of death. In commenting on this case, the *Seattle Sunday Times* states that indiscriminate use of sleeping potions for infants in many cases leads to child murder, unintentional it is true, but none the less murder. The *Times* also deplores the fact that in Washington there is no regulation of the sale of the deadly pill.

Correspondence

Medicinal Foods

PHILADELPHIA, May 11, 1907

To the Editor.—The report of the Council on Pharmacy and Chemistry in regard to medicinal foods in THE JOURNAL, May 11, 1907, is exceedingly important and most instructive. The knowledge that we had before was such as to have led very many exact and thoughtful clinicians to consider these foods of extremely limited value. The report gives most clear and impressive evidence that this is indeed true. In the teaching and practice of dietetics we need more than anything else, I think, greater exactness. We need this most of all in those cases in which the diet is necessarily very restricted and in which, consequently, inaccuracies may be dangerous. The report is especially welcome, therefore, for it is in this class of cases that these foods are most likely to be used and misconceptions regarding their value are very general. The common use of these medicinal foods, so far as I have been able to learn from my contact with those who have some dependence on them, is due chiefly to three things:

1. Their nutritive value is thought to be very great. Often, indeed, it is believed that the very few ounces that can be given provide a reasonably large day's ration. This misconception which is a dangerous one, has been fathered and fostered by many of the manufacturers, and some of them, I have been rather pleased to find, have an honest, though sadly mistaken, belief in the truth of their statements. The report of the Council definitely straightens out this matter. It is of very real and earnest importance that the results of their analyses should become generally known and should be properly appreciated. I have repeatedly had occasion to calculate the actual calorific value of the day's ration of patients whom I found using these foods, by the advice of their physicians, as a more or less considerable part of their diet. In such instances I have found almost as a rule, that they were taking, at most, one third of what they actually required in order to maintain nutrition, usually, indeed, it was less than this. One of the most serious things, therefore, that they were suffering from was more or less severe starvation. I find, in fact from this report of the Council, that I have usually been too generous in the approximate figures that I have used in calculating the value of these foods. It is true, as we are often told—particularly by the manufacturers—that the calorific value is not the only consideration regarding foods, but it is equally true that it is the first and the most essential consideration. No matter how pleasing to the palate or to a disordered digestion a food may be, the amount of it must be sufficient, or the patient's nutrition will suffer, and if the deficiency is very great he will die of starvation. I have long been most thoroughly convinced that many a patient has suffered severely when preparations such as these were being used and that not a few of them have died chiefly of starvation, while the medical attendant, believing what he has been told as to their nutritive value, has attributed the fatality, not to the starvation but to the disease for which the patient was being treated. This report of the Council makes it impossible to escape the feeling that this has occurred even more frequently than had been suspected.

2. A not uncommon cause of the use of these preparations is the fact that it is very easy to remember the names of a number of proprietary foods and to order them, while it is a little more difficult to acquire ready knowledge of a variety of simple preparations that can easily and cheaply be made in the home. If one faces this matter fairly, however, it is apparent that to do this is merely to require the patient to pay dearly in money and perhaps in health, for one's laziness or ignorance, and I think that this plea for their use can scarcely be urged very strongly. On this point, however, I think many a practitioner can throw the responsibility for his use of such preparations back on his medical education. His *alma mater* has treated the teaching of dietetics in such a stepmotherly way that while it might have been made easy for him to use simple and cheap foods properly it seems actually difficult to

him, because largely unknown, and he grasps at the tangible, even though it be costly to his patient and of unknown composition. Much of the use of these foods depends simply on imperfect teaching of dietetics.

3. It is frequently believed—and this belief is most energetically encouraged by the manufacturers—that the medicinal foods are often borne by disordered digestive tracts, when other foods are not. On the contrary, I think that most clinicians that have attempted to use other foods carefully have found themselves continually growing more effectually weaned from the use of such preparations, because others do better. If one acquires a very moderate degree of skill and resource in using simple and comparatively cheap home preparations, one rarely has the slightest temptation to use the proprietary preparations. It is true that if one believes that a few teaspoonfuls of the medicinal foods are equivalent, for example, to a quart of milk, one may readily believe that it is much easier to nourish a patient thoroughly with them than with milk or various home preparations, but such a belief is ridiculously erroneous. If the actual food value of a diet that has been ordered be carefully determined, one finds that one can get more into the patients by other means than by using these foods.

At most, there is but one limited sphere, to my mind in which they have any usefulness. In those very exceptional cases in which capriciousness on the part of the patient, uncertain appetite and irritable digestion combine to make it very difficult to get anything like enough food into him—cases in which even very small added quantities of food are very important and it becomes necessary to provide a great variety—they are sometimes useful, even at a high price, simply because they increase the number of things from which one can choose. If one realizes that the few drams that can be given of these preparations are equal in value to only the same number of drams, or less of milk, one can properly make the patient pay a high price for even a little increase in variety. Such cases, however, are rare. If the same amount of time that is often devoted to studying the advertisements of these foods were given to learning the variety of ways in which more valuable and less expensive foods can be prepared at home the number of such cases would become very small indeed.

A very important disadvantage of these foods, and one that leads me to avoid them almost as much as does their low nutritive value, is their alcohol content. The report of the Council dwells on the fact that if an amount of these preparations sufficient to maintain nutrition were given, the patient would often be made continuously drunk. But even in the small doses that are customarily used the quantity of alcohol is often irritating to the stomach and may be disadvantageous in other ways—particularly in nervous cases. The figures given by the report show that when one gives food in the form of these preparations, he must give, at the same time, approximately, from one to five times the quantity of alcohol that is given of the simple non-toxic foods. Would it not be utterly irrational to be obliged to give a small dose of strychnin, for instance, with each small portion of food, and to be obliged also every time that one increased the food, to increase coincidentally from one to five times the amount of strychnin that one was giving? This is what happens with these preparations in regard to alcohol, and it is so frequently disadvantageous that this objection alone can not but be an exceedingly weighty one.

I have no doubt that, in answer to the report of the Council and to any comments that may be made on it, many practitioners will recall cases in which these preparations have been used in small amounts, and the patients seem to have been kept alive by them. I think we may ask such persons to remember the fact that human beings can live for some weeks without any food at all, if only some fluid is given them, and that temporary starvation often does actual good in suitable instances. But even temporary starvation is a dangerous practice to employ without realizing that one is using it, and protracted starvation is highly dangerous.

DAVID L. FOSATE, M.D.

Danger of Fire in Formaldehyd Disinfection

PHILADELPHIA May 2 1907

To the Editor —The increased efficiency of formaldehyd disinfection as applied at the present time by means of the formalin permanganate method of evolving the gas has brought with it a new danger, uncertain, yet none the less real, in consequence of the fact that on several occasions at least, the mixture has been known to take fire spontaneously.

During the winter of 1906-7 Dr Courtland Y. White of Philadelphia in connection with some disinfection work which he was doing for the Department of Health of the state of Pennsylvania, observed on three occasions that the mixture caught fire after the combination of the constituents had begun and the room had been closed. It was fortunate that the fact was discovered on one of these occasions as the flame was so high as to endanger nearby articles in the room. Suspecting the possibility of impure ingredients, he wrote to Health Commissioner Dixon concerning the matter, and Dr Dixon referred the matter to me for consideration and investigation.

It is well known that there is considerable uncertainty connected with reactions in which potassium permanganate plays a part and that even with inorganic substance as in the Kjeldahl method for the estimation of nitrogen, there is some time a spark or flash of fire when the permanganate is added to the other constituents. In the formalin permanganate method it has been customary to use two parts of formalin to one part of permanganate adding the latter to the former and quickly leaving the room before the violent evolution of gas which shortly takes place has time to affect the operator. Working with quantities in some cases as high as one pound of permanganate, the amount of heat developed must be very great and if there are any uncertain factors present, such as organic matter in the container which has been imperfectly cleaned the danger of possible ignition is that much greater.

The flame which appeared on the occasion described by Dr White was a pale blue flame reaching several feet into the air from the generating container. This agrees with the appearance of the flame of formaldehyd gas which burns freely when ignited even if mixed with a fair proportion of steam as is usually the case.

The gas may be ignited from a 40 per cent solution of formaldehyd by simply heating it and applying a match to the surface after ebullition has begun. And when the formalin permanganate disinfection proportions are used in as small quantities as one ounce of formalin and one half ounce of permanganate, using a beaker for a generator the flame of the ignited gas has been observed to have a length of more than one foot.

In view therefore of the uncertainty regarding the cause of the ignition of the vapor in these observed cases and in recognition of the hitherto overlooked fact that formaldehyd vapor is very inflammable it would be well to practice this method of disinfection with the precautionary measures of using small quantities of the ingredients (not over $\frac{1}{4}$ or $\frac{1}{2}$ lb of permanganate to a charge) in several containers surrounding the container with larger ones containing water being careful to extinguish all gas jets pilot lights fire and other possible causes of ignition and to keep the generators away from the sides of the room where a flame might be communicated to inflammable material. I do not believe that this method of disinfection need necessarily be abandoned but it is essential that its limitations and dangers be not overlooked in its future use.

CHARLES H. LA WALL,

Consulting Chemist to Dr Samuel C. Dixon, Commissioner of Health of the State of Pennsylvania

The Review of Dr Babcock's Book on Diseases of the Lungs

CHICAGO May 3 1907

To the Editor —In THE JOURNAL April 27 page 1453 there appears a review of Dr Robert H. Babcock's recent work on Diseases of the Lungs. In common justice to this excellent treatise and in fairness to the author himself I beg leave to reply to this review.

In the first place the reviewer of Dr Babcock's book fails to take into account the fact that it is not a system that the

author offers us, but a monographic treatise on a special topic, and that in consequence of this he has been subject to certain restrictions of space and scope which prevent him from exhausting in full the diseases under consideration. He has apparently neglected, as well, to read the author's preface, in which is distinctly outlined the limitations of the book. Instead of finding fault as does this reviewer, with the fact that certain diseases such as bronchial asthma and pulmonary emphysema, are not considered in full detail, we should record our obligation to the writer that he has not burdened his text with encyclopedic dissertations on all points, but has in place furnished us with practical readable discussions from a mature judicial standpoint, of the clinical aspects of the various diseases dealt with according to his prefatory claim. The reviewer inadvertently misleads by the statement that pulmonary emphysema is not given more space than is devoted to atelectasis and pneumoconiosis, whereas the fact is that 23 pages are devoted to emphysema while but 15 to the two latter diseases together. He criticises the scant space given to the consideration of acute miliary tuberculosis apparently forgetting that it is a book on diseases of the lungs that he is reviewing and not a treatise on general medicine, and unmindful of the author's explanation in his text of his reasons for excluding it from extended description. The reviewer again depreciates the comparatively large amount of space devoted to symptomatology apparently having little faith himself in purely clinical aspects of disease. In this criticism he fails to allow for the fact that the case illustrations which are especially rich and varied and add greatly to the interest of the book are included in the sections on symptomatology thereby swelling their bulk.

The reviewer next criticises the author for mentioning the names of physicians to whom he is indebted for the referred cases in his clinical reports. In thus signifying his professional obligations the author follows an old custom which has characterized the amenities of English and American medical literature for many decades. It is one of those customs of which, unfortunately there are too few surviving in this busy age, which mark the pleasant courtesies of other times.

The review closes with a commendation of the author's style but evidently the reviewer can not permit himself an unqualified approval for abashed apparently at his one indulgence in praise he proceeds to charge a lack of emphasis and force to the "author's elegance and fluency." "Emphasis is the insistence of a weak argument," and the intelligent reader will acknowledge his obligations to the distinguished author for leaving something to his discrimination and understanding. "There is not a single epigram in the book," says the reviewer in closing. The making of epigrams in medicine is a dangerous business. In no branch of science is truth so relative a thing as in medicine. What is to day an epigram becomes a glaring half truth to morrow. "Experience is fallacious and judgment fleeting" wrote Hippocrates many centuries ago.

It must be humiliating to the author to have the only unqualified approval of his work consist of a commendation of the author's advocacy of infection (in tuberculosis) as opposed to the old idea of hereditary predisposition. Thus, again are the common virtues applauded while the many higher excellences are passed over in silence. Dr Babcock has already made good in his excellent work on 'Diseases of the Heart' which has met with a most favorable reception at the hands of the profession. 'Good meat needs no basting' and those who read his companion work on the diseases of the lungs will not be disappointed. ARTHUR P. FILLIOTT, M.D.

[I have no wish to enter into any controversy with Dr Elliott about the book itself, but I wish to correct certain impressions which his letter may make. It is true that I did not recognize in Dr Babcock's book a monograph. I looked on it rather as a systematic account of the diseases of the lungs and pleura noting in consequence the necessity of restrictions both in space and matter. Moreover I read carefully both preface and text. I still feel that the detailed accounts of numerous cases without postmortem notes might well have been omitted so that space might have been spared for more important matter. Of what value for example is the case recently seen in Elgin, Ill., in consultation with Dr O. T. Pitkin since at

present writing it is too soon to report the outcome of this case" (p 104) And "the only excuse for so detailed a narration of another case stretching over two and three-fourths pages, 'is its instructive portrayal of one of the modes in which this truly terrible disease (secondary pneumonia) slays its victims,' (pp 210 212) Moreover, I am ready to repent that relatively too little space is recorded both to pulmonary emphysema and to acute miliary tuberculosis of the lungs On page 350 I fail to find any explanation in the author's text of his reasons for excluding acute miliary tuberculosis of the lungs from extended description, Dr Elliott to the contrary notwithstanding But I do find expressed a reason why "it is considered practical to recognize" it, and in this I thoroughly agree with Dr Babcock Dr Elliott censures me for criticising Dr Babcock for mentioning the names of physicians who called him in consultation Yet why should these names be given? Why burden the reader with them? What matters it where the patient lives whether in Macomb, Ill, or Ottumwa, Iowa? And surely the amenities of English and American medical literature severely demand the name of an earlier consultant, proved to have been in the wrong by a subsequent postmortem examination (p 230), even though the family physician and Dr Babcock also fell into the error

Dr Elliott's last paragraph is not just Several commendations of the book appear in the original review, to which the reader is referred It is true that I stated that "at times the author's elegance and fluency get the better of strength and force" This I fully believe and I count it not wholly a disparaging criticism And as for the epigram, Dr Elliott, I thank you for the illustration Do you believe that this ancient epigram of Hippocrates, 'Experience is fallacious and judgment fleeting' is to become a glaring half truth to-morrow?—THE REVIEWER]

The Neglect of the Anamnesis.

SCRANTON, PA., April 26 1907

To the Editor—I agree with Dr Bayard Holmes in his recent article (THE JOURNAL April 20 page 1340) that the patient is our study and that regardless of surroundings, conditions or circumstances he expects us to cure him without reference to the name of the disease The patient first asks "Can you cure me?" Second "How long will it take?" Scientific diagnostic means such as the Widal typhoid reaction used to the exclusion of common sense will not make the patient well any quicker, as they are only confirmatory and there are enough other signs to teach one that he is dealing with a sick man I cite this method not to condemn it, but to illustrate the tendency to forget that we are treating the genus *Homo* and not the bacilli

The first and foremost factor is the patient Get him well Forget if you will all the technic or, if you will, elaborate it to your heart's content, but for the love of humanity use your reason and treat your patient even as you would be treated We must study our patients To know that we have not neglected our patients will not only bring us comfort, but will bring us nearer perfection and nature and natural processes

D W FINE, MD

Temperance Lunch.

HARTFORD, CONN May 8, 1907

To the Editor—I have received a number of inquiries relating to the temperance lunch proposed at Atlantic City June 6 It should be distinctly understood that this occasion is not to promote any particular theory, or society, or any special effort to enlist or pledge any one to the so called temperance cause The purpose is simply to gather, and informally talk over the many questions which are arising about this problem It seems eminently fitting that the American Medical Association the largest medical society in the world, should recognize this subject in this simple way and indicate that we are not indifferent to the medical and hygienic interests which center about it

The Society for the Study of Alcohol has simply volunteered to manage and conduct this event in response to the request of a number of persons who feel that the members of the

American Medical Association should show an equal interest in this subject to that of the great foreign societies At the British Medical Association, at Toronto, last fall a similar lunch attracted over 600 persons, the full limit of the hall The whole affair was informal and each speaker represented himself personally, and it was a frank, open expression of opinions

I appeal, therefore, to every physician of the Association to show his interest in the general subject by making this occasion prominent and eventful, and by attending this lunch with his family and hearing what may be said by some of the leaders of the profession

I shall be very glad to give any further information or details
T D CROTHENS MD

Dentists Also Dupes of Nostrum Makers—A Letter with Spirit

SOMERVILLE, MASS., April 17, 1907

To the Editor—I wish to write a word of praise for the great work THE JOURNAL is doing in educating the medical profession on the nostrum question Keep up your good fight for ethical medicine Ten years ago, when I was in the drug business I realized that the medical profession was being lowered by the nostrum vendors, and I think we are indebted to the *Druggists Circular* for the stand it has always taken for ethical medicine The medical profession has been and some of its members are still being bluffed by the proprietary men but nothing compared to the dental profession The dentist is the acme of credulity About a year ago I read a paper before three Massachusetts dental societies on the subject It was sent to three leading dental trade journals They all refused to publish it I have read "Adding Insult to Injury" (THE JOURNAL, Jan 26, 1907, page 340) referring to Antikamnia This is fine You strike right from the shoulder and you touch one phase of the subject which I am ashamed to say I had overlooked I intend to act, however Here is a copy of a letter which I am mailing to Merck to day

DEAR SIRS—I am astonished to find in the columns of the *Archives* advertisements of the two fake preparations Antikamnia and Phenalgin especially after they have been so thoroughly exposed by THE JOURNAL of the American Medical Association When my subscription expires I am through with you and your journal Furthermore if you continue to carry these ads I shall cease prescribing and using Merck's products of every description

Book Notices

AMERICAN PRACTICE OF SURGERY A Complete System of the Science and Art of Surgery by Representative Surgeons of the United States and Canada Editors Joseph D Bryant MD and Albert H Buck MD Complete in Eight Volumes Illustrated Volume II Muslin Binding Pp 778 Price \$7.00 New York William Wood & Co

The first volume of this work was recently reviewed in *ex tenso* in these pages, and the second volume, just received, maintains the same general standard In part vi which deals with such infections as leprosy, plague, glanders, anthrax, actinomycosis, mycetoma, rhinopharyngitis mutilans and scurvy, the space assigned to some of the subjects is entirely out of proportion to the importance of the subject For instance twenty seven pages are devoted to leprosy a rare curi-osity in this country, and but five pages to actinomycosis, with but a single paragraph on symptomatology although actinomycosis is common in comparison with leprosy and presents such varied manifestations as to make it worthy of more thorough consideration In the chapter on syphilis it is stated that "up to the present time the cause of syphilis has not been discovered" notwithstanding the fact that the claims made for the *Spirocheta pallida* as the infectious agent seem most convincing if not overwhelming The use of poultices of absorbent cotton saturated with 2 per cent carbolic acid solution for infections, as recommended on page 155 when applied to the extremities, carries great danger of producing gangrene of the fingers or toes, as has been noted repeatedly In the chapter on 'Surgery of Diseases of the Skin,' several subjects are handled which are also included in other chapters of this volume—for instance,

fungulous, carbuncle, anthrax, glanders, etc.—so there is considerable unnecessary repetition. The present day extensive use of electricity in all lines of industry gives rise to frequent electric burns and shocks, the immediate and after effects of which are often very distressing. The subject of "The Effects of Electric Currents," therefore, deserves more thorough consideration than it receives in the space of scarcely a page. There are other chapters in this volume, however, which are very good, notably among which may be mentioned those on "Gangrene and Gangrenous Diseases," "Surgical Diseases of the Lymphatics," "Gunshot Wounds," etc., so that the entire volume makes a fitting second in this great work.

ALCOHOL: The Sanction for Its Use Scientifically Established and Popularly Expounded by a Physiologist. Translated from the German of Dr. J. Starke. Cloth. Pp. 317. New York and London: G. P. Putnam's Sons. 1907.

This book presents a candid defense of the use of alcohol as a beverage, with arguments drawn from scientific experiments as well as from experience and current opinion. The scientific facts appear to be, in the main, correct, but the propositions which the author attempts to establish will seem to many open to question. He distinguishes sharply between the moderate use of alcohol and its use for purposes of intoxication, as if intoxication were a matter of deliberate choice. The moderate drinker, according to him, drinks for the purpose of stimulation, the drunkard, to obtain stupefaction. It is a delicate task to decide on the motives of men, but, while some men drink to drown their sorrows, it would seem to be the teaching of experience that others reach the stage of drunkenness, even when they are habitual drunkards, by taking the first glass from a desire for stimulation. The author pronounces the dictum "The alcohol of alcoholic drinks does not of itself possess the property of inducing persons to take ever increasing amounts." His ground for this statement is thus expressed: "We are all familiar with the 'leading to constantly increasing quantities.' If it were correct, all those who use alcohol must end in drunkenness." The fallacy of this is shown by the very words moderate and temperate, which of themselves indicate an effort of the individual to restrain himself, to oppose a tendency. Shall we say that the pneumococcus has no tendency to produce disease because many individuals harbor it without dying of pneumonia? The third proposition is that the moderate use of alcohol has nothing to do with the production of any disease. This statement seems to be fairly well sustained, although there might be differences of opinion as to the meaning of the word moderate. His discussion of the part played by alcohol in the etiology of disease will convince the lay reader of uncertainty of the conclusions drawn from cases complicated by so many etiologic factors, and he can hardly escape attributing the same uncertainty to argument drawn from the successful use of alcohol as a medicine. If physicians have been mistaken in attributing disease to alcohol, why may they not have been equally mistaken in assigning alcohol as the curative agent? The account of the action of alcohol as determined by experiment is clear but not detailed. The author holds that alcohol is a nutrient possessing the specific property of stimulating the nervous system, but not a poison in the popular sense of that term. The position of the author will undoubtedly invite criticism, and it is to be hoped that such criticism will result in establishing the truth concerning alcohol and alcoholic beverages.

MANUAL OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE EYE. By Edward Jackson, A.M., M.D., Professor of Ophthalmology in the University of Colorado. Cloth. Pp. 615. Price \$2.50 net. Philadelphia: W. B. Saunders Co. 1907.

In this second edition Dr. Jackson has added much material that has proven of value since the appearance of the first edition, especially the studies of new conditions and of new remedies and means of treatment. The book is intended as a manual for the beginner in ophthalmology and for the general practitioner. Abundant references are given to the original sources of the matter presented, making it very easy to go more deeply into a given subject if desired. The chapters on refraction are particularly valuable coming, as they do, from a man of Dr. Jackson's peculiar ability and painstaking care in this particular branch of ophthalmology. Among the important additions which have been made are a number of the latest

diagnostic methods, such as testing the light sense, mapping central scotomata, "fogging" method in refraction, diseases and congenital defects of the ocular muscles, etc., etc. The book might be more freely illustrated with advantage, as in no work are illustrations of as much value as in one intended for beginners. The illustrations here are practically all schematic, an advantage always to the student who first approaches a subject. There is a fairly complete list of "remedies and applications," and the book closes with a consideration of the common operations in ophthalmology.

RACE CULTURE OR RACE SUICIDE? A Plea for the Unborn. By Robert Reid Rentoul, Doctor of Medicine. Member of the Royal College of Surgeons, England. Cloth. Pp. 182. Price 7s. 6d. net. (S1.87). New York: The Walter Scott Publishing Co. 1906.

The author's line of reasoning runs something as follows: The race is degenerating physically, as is shown by the increasing amount of illness, the rejections of recruits for the Army and Navy, the number of deaf and blind. He estimates the number of those affected with temporary or permanent physical disability as one in five. Mental degeneration is shown by insanity, criminality, vice, etc., and the number of cases is estimated at one in fifty, although, perhaps, this is too low. The causes of degeneracy are put as the intermarriage with lunatics, idiots and feeble minded persons, child marriages, forbidding or restraining the healthy from marriage, encouraging the marriage of the unfit, release of asylum patients before recovery, overwork of the young brain, unsuitable employment for women and children, abuse of alcohol, undesirable immigration, venereal diseases, abortion and sexual excess. The legal restrictions of marriage in various countries are described, and then the author advances the remedy which he advocates, viz. the sterilization of certain degenerates so that they can not transmit their enfeebled constitution to posterity. He claims that this proposal has received support from a considerable number of medical men. A large mass of evidence is presented, and while one may not agree with the author's conclusions, it must be admitted that *a priori* case is made out. If degeneracy threatens the extinction of the race the legal restrictions of marriage for the unfit is certainly an appropriate, although it may not be an effective, remedy. It will seem to many that voluntary or forced sterilization can be imposed on so few as to make it a measure of doubtful utility. However, it is desirable that this remedy be thoroughly canvassed, and it is the mission of this book to bring the remedy into public notice, a mission that it is admirably adapted to fulfill.

PSYCHOLOGY APPLIED TO MEDICINE. Introductory Studies by David W. Wells, M.D., Lecturer on Mental Physiology in Boston University Medical School. Cloth. Pp. 141. Price \$1.50 net. Philadelphia: F. A. Davis Company. 1907.

This takes up the subject in a simple and fundamental manner and works up to a pertinent criticism of the too common disregard of the practitioner for the potency of suggestion. The book will aid in an understanding of the success of quacks, "patent medicine" peddlers and other means which often cure without material agencies.

Association News

ATLANTIC CITY SESSION

The railroad rates to the annual session of the American Medical Association at Atlantic City, June 4-7, were described in THE JOURNAL, May 4. That issue, the Atlantic City number, contained an illustrated description of Atlantic City, with the preliminary programs of the sections, lists of hotels and their prices, meeting places, etc. The rates mentioned in that issue did not refer to the Western Passenger Association, which granted one fare plus \$2 for the round trip. The same rate was authorized by the Central Passenger Association. In the territory of the Trunk and the New England passenger associations the rate is one fare plus \$1 for the round trip.

A change has been made in the rules for transcontinental tickets from California on sale May 25 to 27. The return limit will be 60 days instead of 90 days. Other tickets, on sale May 20 and 21, still have the final limit of 90 days.

It is understood that detailed information has been furnished to all ticket agents and that they will provide purchasers of tickets with full information as to rates, routes, stopovers, etc

American Medical Special

A correspondent asks about the route of the American Medical Special. This Pullman vestibuled train is to run as a section of the Pennsylvania's Chicago New York eighteen hour train. The schedule insures it a fast, steady run, and its equipment will be as good as that on the famous flyer. The Susquehanna River at Harrisburg will be passed about 6 o'clock in the morning, giving the passengers an opportunity to enjoy the beautiful country between Harrisburg and North Philadelphia, at which point the train turns off to Atlantic City, it runs from Chicago to Atlantic City without change and does not enter the Broad Street station.

This train will leave Chicago, Sunday, June 2, at 3 p m, reaching Atlantic City early Monday afternoon. The fare is \$21.50 for the round trip, Chicago to Atlantic City and return. For sleeping car reservations and further information one may address Mr C L Kimball, assistant general passenger agent, 2 Sherman Street, Chicago. Special cars may be arranged for by parties of sufficient size, from west, northwest or south, who wish to join this special train.

Tickets are on sale at the special rates from Western passenger Association territory, May 30 to June 3. Tickets may read by way of Washington if desired, so as to allow arrangements to be made for a side trip to the Jamestown Exposition. A correspondent has called attention to the fact that advertisements in THE JOURNAL, May 4, give the final limit of leaving Atlantic City, after tickets have been extended, as June 14, while the statement on page 1522 in the Atlantic City writeup named June 18. This is explained by the fact that the railroads first named June 14 as the limit, but page 1522 went to press late enough to include later information, after the date had been extended to June 18.

Jefferson Medical College Clinics

The Jefferson Medical College has arranged a series of clinics, ward walks and demonstrations for visiting physicians on June 8, 10, 11 and 12. These will be in connection with the dedication of the new hospital, details of which were given in the Atlantic City Number (May 4) of THE JOURNAL.

SATURDAY JUNE 8

- 9 30 to 11 30 Clinic, Frontal Sinus Prof. Gustave Killian
- Freiburg and Laryngologic Clinic, Prof. Theodore Gluck Berlin
- 9 30 to 11 30 Physiologic Laboratory Prof. Albert P. Brubaker
- 2 00 to 2 00 Surgical Clinic Prof. J. Chalmers DaCosta and guests
- 12 00 to 2 00 Medical Ward Walks Prof. H. A. Hare and Prof. James C. Wilson
- 2 00 to 4 00 Gynecologic Clinic Prof. F. E. Montgomery
- 2 00 to 4 00 Neurologic Ward Walks Prof. F. X. Dercum
- 4 00 Regional Anatomy (white board sketches) Prof. George McClellan
- 00 Pathologic Laboratory Prof. W. M. L. Coplin

MONDAY JUNE 10

- 9 30 to 11 00 Obstetric Clinic, at Maternity Prof. Edward P. Davis
- 10 00 to 11 30 Gynecologic Clinic Prof. Orville Horwitz
- 11 00 to 12 00 Surgical Clinic Prof. John H. Gibbon and guests
- 2 00 to 4 00 Ophthalmologic Clinic Prof. Howard F. Hansell
- 4 00 to 5 00 Clinical Medicine Prof. Solomon Solis Cohen

TUESDAY JUNE 11

- 10 00 Mastoid Clinic Prof. S. MacCuen Smith
- 11 00 Orthopedic Clinic Prof. H. Augustus Wilson
- 12 00 Pediatric Ward Walks Prof. Edwin E. Graham
- 1 00 Dermatologic Clinic Prof. Henry W. Stelwagon
- 2 00 Laryngologic Clinic Prof. D. Braden Kyle
- 3 00 Ophthalmologic Clinic, Associate Prof. William M. Sweet
- 4 00 Gynecologic Ward Walks Asst. Prof. John M. Fisher

WEDNESDAY JUNE 12

- 10 00 to 12 00 Gynecologic Clinic Prof. F. E. Montgomery
- 11 00 Op. on Dr. John C. DaCosta
- 1 00 to 2 00 Surgical Clinic Prof. J. Chalmers DaCosta
- 2 00 to 5 00 Obstetric Clinic at Maternity Prof. Edward P. Davis

The Public Service

Army Changes

Memorandum of changes of stations and duties of medical officers of the U S Army for the week ending May 11 1907

Lambert Samuel E, asst. surgeon ordered to accompany Major L. R. Morris surgeon, from Fort Logan Colo. to Army General Hospital Washington Barracks D C. Asst. Surgeon Lambert will on arrival at Washington report to Major William H. Arthur surgeon president examining board for examination for advancement. Instead of reporting at Presidio of San Francisco as directed in previous orders.

Snyder Henry D surgeon leave extended 8 days

Lyster William J L asst. surgeon, granted 10 days leave of absence

Noble Robert I, asst. surgeon relieved from duty at Fort Casey, Wash. and will report to this city and report to the chairman of the Isthmian Canal commission for duty with the commission on the Isthmus of Panama

Scott George H asst. surgeon granted 30 days leave of absence

McCaw Walter D surgeon detailed to represent the medical department of the Army at the fourteenth International Congress on Hygiene and Demography to be held at Berlin Germany Sept 23 to 29 1907

McCulloch C C Jr surgeon now at Ancon Canal Zone will proceed at once to Fort Meade S D for temporary duty

Devereux J R, asst. surgeon granted 30 days leave of absence

Barney Charles N asst. surgeon, granted 10 days leave of absence

Wertebaker Clark I contract surgeon left Madison Barracks N Y and arrived at Fort Wadsworth N Y for temporary duty

Bell Leonard P contract surgeon arrived at Fort Riley Kans for duty

Dillon G Parker, contract surgeon returned to Fort Bliss Tex from temporary duty at Fort Apache Ariz

Hennings Oswald F contract surgeon arrived at Fort Bairan Fla for temporary duty

Ingalls Raymond E dental surgeon left Fort Omaha, Neb for duty at Fort Crook Neb

Navy Changes

Changes in the medical corps U S Navy for the week ending May 11 1907

V C B Means surgeon on discharge from treatment at the Army and Navy General Hospital Hot Springs, Ark., ordered home and granted sick leave for three months

M S Lillott surgeon detached from the *St. Louis* and ordered to duty at the Navy Yard Norfolk Va in connection with fitting out the *Olympia* and to duty on board that vessel, when placed in commission

H C Curl surgeon ordered to additional duty at the Naval Medical School Hospital Washington D C

E S Bogert Jr surgeon on expiration of leave ordered to the *Albatross*

I W Kite surgeon detached from the *Hearsarge* and ordered to the *Franklin*

G H Barber surgeon detached from the *Baltimore* when placed out of commission granted leave for one week and thence ordered to *Hearsarge*

R A Bachmann passed asst. surgeon, detached from the *Franklin* and ordered to the *St. Louis*

J R Waggener medical director having been examined by a retiring board and found incapacitated for active service on account of disability incident to the service is retired from active service May 6 1907 under provisions of Sec. 1473 R S

E M Brown passed assistant surgeon detached from the Bureau of Medicine and Surgery Navy Department and ordered to duty at the Naval Hospital New Port Lyon, Colo

W H Short R I Longabaugh, F A Kottes M A Stuart asst. surgeons appointed assistant surgeons with rank of lieutenant junior grade from May 4 1907

J H Inge surgeon detached from the *Albatross* and ordered to continue treatment at the Naval Hospital Mare Island Cal

Public Health and Marine Hospital Service

List of changes of stations and duties of commissioned and non-commissioned officers of the Public Health and Marine Hospital Service for the seven days ended May 8 1907

Wasdin I surgeon granted leave of absence one month or so much thereof as may be necessary on account of sickness from May 10 1907

Oakley J H I A surgeon directed to proceed to Seattle Wash for special temporary duty on completion of which to rejoin his station

Fox C P A surgeon relieved from duty at San Francisco Quarantine and directed to proceed to St. Michaels Alaska and assume charge of the service at that port

Trotter F I I A surgeon granted leave of absence for 10 days from May 8 1907

Vogel C W I A surgeon granted leave of absence for 7 days from March 27 1907 under Paragraph 191 of the Service Regulations

Burkhalter J T P A surgeon granted leave of absence for 27 days or so much thereof as may be necessary on account of sickness from April 20 1907

Warren B S P A surgeon granted leave of absence for 7 days from April 30 1907 under Paragraph 191 of the Service Regulations

Warren B S P A surgeon granted extension leave of absence for 7 days from May 6 1907

Steger F M asst. surgeon granted leave of absence for 10 days on account of sickness from April 24 1907

Fbert H I asst. surgeon assigned to duty on Revenue Cutter *Terre* effective May 15 1907

Hurley J R, asst surgeon directed to proceed to San Francisco, Cal for duty on the Revenue Cutter *Thetis*
Curley, C P acting asst surgeon granted leave of absence for 4 days from May 7 1907
Foster J P C acting asst surgeon granted leave of absence for 5 days from May 6 1907
Griffiths T H D, acting asst. surgeon leave of absence granted for 21 days from April 12 1907 amended to read 16 days only
Hamilton, H J acting asst surgeon granted leave of absence for 9 days from May 4, 1907
Stevenson J W acting asst surgeon leave of absence for 2 months without pay granted from Feb 8 1907 amended so as to grant him but 1 month and 15 days without pay

APPOINTMENTS

Dr James R Hurley of California commissioned (recess) as assistant surgeon, Public Health and Marine-Hospital Service May 4, 1907
Dr William M Bryan of Virginia commissioned (recess) as assistant surgeon Public Health and Marine-Hospital Service, May 4 1907
Dr Anthony J Lanza of the District of Columbia commissioned (recess) as assistant surgeon Public Health and Marine-Hospital Service May 4 1907

Health Reports

The following cases of smallpox yellow fever cholera and plague have been reported to the Surgeon General Public Health and Marine-Hospital Service during the week ended May 10 1907

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION CONTRACT PRACTICE INSURANCE FEES, MEDICAL LEGISLATION, ETC

The Business Side of General Medicine

In a recent number of the *Texas State Journal of Medicine* Dr J E Dildy of Lampasas makes some pertinent and practical suggestions on the above topic. Lack of space forbids production of the paper as a whole, but many of Dr Dildy's observations are so forceful as to be worthy of reproduction.

Speaking of the position of the medical profession, he says: "We are professional men in every sense of the word, we have the mental labor of lawyers, the moral standing of ministers, the technical knowledge of organized artisans and the business qualifications of school children. The average man will give a lawyer \$300 to \$500, together with a lifetime's praise, to keep him out of the penitentiary for from two to ten years, and at the same time he will raise a phosphorescent glow and a kick that can be heard around the world if a doctor charges him \$50 to \$100 to keep him out of hell for a lifetime."

Commenting on the amount of work done by members of the profession, Dr Dildy says: "We are the only people under God's ethereal tent to day who keep open shop 24 hours each day and 365 days in each year. We are also the only laborers to keep on working for people who do not pay."

The attitude of a thinking member of the profession toward charity work is very well summarized in Dr Dildy's discussion of the amount of unremunerative work done by physicians. I can carry my part of charity with as good a grace as most men. I can go through rain, snow or mud and do my best, provided the case is one of worthy need, but to reward continually downright rascality, wilful drunkenness and wanton laziness is getting out of my line." The logic of his statements no one will deny, although very few of us have the moral courage to do what we know is our duty to our selves, our patients, and our families along these lines.

The following should be pondered on by every practicing physician: "The average doctor tries to do too much work. Every doctor wants everybody to patronize him. He likes to be going night and day, rain or shine, Sunday or week day, hot or cold. This is a business mistake. It wears a doctor to a frazzle. It gives him no time for bill collecting and business matters, no time for patients who naturally feel neglected and are slow pay as a consequence. A doctor can do better work, more good, and build up a more enviable reputation if he coolly takes his time and is careful and painstaking in his examinations and if he takes into consideration the pathological conditions he meets."

Dr Dildy is entitled to special praise for his honesty and clear sightedness regarding the value of professional service. He says: "The prices of our office work and consultations are usually disgracefully small. This 'let me see your tongue' off hand, hurry scurry kind of professional laziness is not worth the price we get for it. I have lost home, friends and fortune by not examining my patients carefully." Every physician who is honest with himself will admit the truth of the above statement. Every man knows that when he attempts to diminish the amount of care and attention to details which he gives each one of his patients, he thereby diminishes the value of his services. He also knows that, in the long run the man who takes pains is the man who receives large fees.

Regarding the sins of the commission of which we are all guilty

himself freely and frankly. He says: "We fail to be professional. We talk shop too much. Silence is golden in medicine. My mouth gives me most of my trouble. What I say is what keeps me awake nights. We are too prone to give free advice. We sit and smile while some disgruntled chronic peels our competitor. If, instead, we would shut him up we would grow in our own estimation and make a more favorable impression on the public."

As to his suggestions for remedies for existing evils he is equally emphatic. The following advice is worth considering: "We could be as ethical as the law fraternity, who by their union of action have stamped on our statute books nearly every law by which we are governed. When doctors cast aside all petty jealousies and join and attend medical associations, money comes their way. The best trade I ever made in a business sense was when I paid \$2.50 to join my county society."

His closing words of advice are: "Let us do less work and better work. Let us not raise prices until we have raised our standard of service on a par with our ability. Let us work honestly and not get lazy, keep enthusiastic and join our county societies, take postgraduate work and familiarize ourselves with modern medicine. Let us not dicker in futures nor drink booze, but buy books and drink freely of the fountain of knowledge. Let us work some, and play some, read some and collect some, and make money whenever we can."

It is a most gratifying indication of the increased interest in the practical side of medicine that papers like the above are becoming more and more common in our county societies. Every medical organization ought to have, at least once a year, a plain, practical paper on these matters from some clear-headed, progressive member, followed by a general discussion from the members of the society. It will be found in many instances that such a program will help to clear away old animosities and misunderstandings by bringing about a free discussion and consideration as well as stimulating many physicians to a consideration of various phases of these questions, the importance of which has not heretofore been properly estimated.

Legislation in Illinois

The work of the state legislature has been fairly satisfactory, so far as the medical profession of the state is concerned. Several of the bills were described in Illinois news in THE JOURNAL last week. The two introduced by the State Board of Health were passed, one enlarging the board's authority over health matters, the other authorizing reciprocity in licensure and empowering the board to define a medical college in good standing. The Pure Food Bill was also passed in the last hour of the session. It is impossible to say at present just what are its provisions. The appropriation for the State Board of Health is increased over that of previous years. The appropriation for the State Board of Charities, while not as large as asked for, nor as recommended by Governor Deneen, is large enough to allow some of the reforms contemplated. The bill appropriating \$386,000 for the University of Illinois to purchase the property of the College of Physicians and Surgeons in Chicago was passed at the eleventh hour.

A bill directing that all chronic insane patients now kept in county poor houses and asylums be sent to the state institutions at the state's expense will put an end to a feature of county poor houses which has been the subject of much criticism. For the third time the legislature refused to establish an osteopathic board of examiners or to place an osteopath on the State Board of Health. The so-called anti-vivisection bill, the mental healers' bill, the itinerant vendors' bill, as well as a number of other objectionable bills, failed to pass.

The only bill to which the medical profession can take any exception is the bill establishing a board of examiners in optometry. It is earnestly hoped that this will be vetoed by the governor as it has been alleged during both the present session of the legislature and that held two years ago that it was introduced for ulterior purposes and in favor of certain individuals for personal reasons.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

NEW YORK State Boards of Medical Examiners Albany May 21-24. Chief of Examining Division, Charles F. Wheelock. Albany.

NEBRASKA State Board of Health State House Lincoln May 25-26. Secretary Dr. Geo. H. Brash. Beatrice.

INDIANA Board of Medical Registration and Examination Room 120 State House, Indianapolis May 28-31. Secretary Dr. W. T. Gott. Indianapolis.

NEW MEXICO Board of Health, Santa Fe June 3. Secretary Dr. B. D. Black. Las Vegas.

MINNESOTA State Board of Medical Examiners St. Paul June 4-5. Secretary Dr. W. S. Fullerton. St. Paul.

MARYLAND Homeopathic Board of Examiners Baltimore June 4-5. Secretary Dr. Joseph S. Garrison. 848 W. North Ave., Baltimore.

OHIO State Board of Medical Registration and Examination Cleveland Columbus and Cincinnati, June 10-12. Secretary Dr. George H. Matson. Columbus.

KENTUCKY State Board of Health Louisville, June 11. Secretary Dr. J. N. McCormack. Bowling Green.

SOUTH CAROLINA State Board of Medical Examiners Columbia June 11. Secretary Dr. W. M. Lester. Columbia.

OKLAHOMA Board of Medical Examiners Guthrie, June 11-12. Secretary Dr. J. W. Baker. Enid.

KANSAS State Board of Medical Registration and Examination Kansas City Kansas June 11-13. Secretary, Dr. T. P. Hatfield. Grenola.

IOWA State Board of Medical Examiners Des Moines, June 11-13. Secretary Dr. Louis A. Thomas. Des Moines.

FLORIDA Homeopathic Board of Medical Examiners Jacksonville June 18. Secretary Dr. C. W. Johnson. Jacksonville.

DELAWARE Board of Medical Examiners Dover June 18. Secretary of the Medical Council, Dr. P. W. Tomlinson. Wilmington.

DELAWARE Homeopathic Board of Medical Examiners Wilmington June 18. Secretary, Dr. C. M. Allmond. Wilmington.

NEW JERSEY State Board of Medical Examiners, State House Trenton June 18-19. Secretary Dr. J. W. Bennett. Long Branch.

VIRGINIA State Medical Examining Board, Lynchburg June 18-21. Secretary Dr. R. S. Martin. Stuart.

WYOMING Board of Medical Examiners State Capitol, Cheyenne June 19. Secretary Dr. S. B. Miller. Laramie.

MARYLAND Board of Medical Examiners Baltimore, June 10-22. Secretary Dr. J. McPherson Scott. Hagerstown.

PENNSYLVANIA State Board of Medical Examiners 708 Locust Street Philadelphia and in Pittsburgh Academy Ross and Diamond Streets, Pittsburgh June 23-28. Secretary Dr. Winters D. Hamaker. Meadville.

PENNSYLVANIA Homeopathic Board of Medical Examiners N. W. Corner 15th and Cherry Streets Philadelphia June 25-28. Secretary Dr. C. S. Middleton. 1523 Girard Avenue Philadelphia.

PENNSYLVANIA Eclectic Board of Medical Examiners Harrisburg June 25-28. Secretary Dr. W. H. Blake. 2116 N. Marline Street Philadelphia.

TEXAS State Board of Medical Examiners, Austin June 25-27. Secretary Dr. T. T. Jackson, San Antonio.

North Dakota April Report.—Dr. H. M. Wheeler, secretary of the North Dakota State Board of Medical Examiners, reports the written examination held at Grand Forks, April 2-4, 1907. The number of subjects examined in was 14, percent age required to pass, 75. The total number of candidates examined was 10, of whom 9 passed and 1 failed. Three reciprocal licenses were granted at this examination. The following colleges were represented:

College	PASSED	Year Grad	Per cent
University of Minnesota		(1907)	85 80
Lincoln Med Coll		(1904)	8
Jefferson Med Coll		(1904)	87
Laval University Quebec		(1900)	78
University of Toronto Ont		(1903)	8
University of Christiania Norway (1898)	85	(1903)	87 (1904) 75
Trinity Med Coll		(1903)*	
LICENSED THROUGH RECIPROCITY			
National Medical University Chicago		(1900)	Illinois
Rush Med Coll		(1907)	Illinois
University of Iowa		(1900)	Iowa

*Percentage not given

California's New Examining Board.—At a meeting of the new Board of Medical Examiners May 3, in San Francisco the organization was completed as follows: President, Lincoln Cothran, San José, vice president, J. Park Dougall, Los Angeles, treasurer, E. Sisson Oakland, secretary, Charles L. Tisdale, Alameda, associate secretary, F. Dudley Tait, San Francisco. It was unanimously resolved "to cooperate with state examining boards and state medical societies in giving publicity to revoked certificates and irregularities in colleges and to send a copy of said resolution to every state board and to each

of the California colleges" The next examination will take place in San Francisco, Aug 6, 1907 All applications must be filed at least two weeks prior to said date

Texas Holds Last Meeting Under Old Law—Dr T T Jackson, secretary of the regular Board of Medical Examiners, states that a meeting of that board will be held at Austin, June 25, 26 and 27, 1907, which will be the last meeting before the new law goes into effect This will be the last examination to which any person will be admitted except one who has graduated from a reputable medical college having not less than four sessions of at least five months each

COUNCIL ON MEDICAL EDUCATION OF THE AMERICAN MEDICAL ASSOCIATION

Third Annual Conference, held at Chicago, April 29, 1907

The Chairman, Dr A D BEVAN, Chicago, presiding

Besides the members of the Council, eighty four delegates were present, representing 22 state examining boards, 18 state medical societies, the 3 departments of the government services, 3 college associations, and 14 literary and medical colleges

DELEGATES

FROM STATES AND STATE BOARDS Colorado, S D Van Meter, Denver, Idaho, W F Howard, Pocatello, Illinois, George W Webster, Chicago, Indiana, W A Spurgeon, Muncie, and W T Gott, Crawfordsville, Iowa, A P Hanchett, Council Bluffs, Kentucky, Chester A Mayer, Louisville, Massachusetts, E B Harvey, Boston, Michigan, Beverly D Harrison and Oscar Le Seure, Detroit, Minnesota, W S Fullerton, St Paul, Missouri, R H Goodier, Hannibal, and A H Hamel, DeSoto, Nebraska, Benjamin F Bailey, Lincoln, New Jersey, J W Bennett, Long Branch, New York, George E Corham, Albany, and William Warren Potter, Buffalo, North Dakota, F R Smith, Bismarck, Ohio, H E Beebe, Sidney, and A Ravogli, Cincinnati, Oklahoma, J W Baker, Enid, Oregon, A C Pantan, Portland, Utah, Ralph T Richards, Salt Lake City, Vermont, W Scott Nay, Underhill, Washington, J B Engleson, Seattle, West Virginia, John L Dicker, Wheeling, Wisconsin, W T Sarles, Sparta, A P Andrus, Ashland, J V Stevens, Jefferson, P H McGovern, Milwaukee and A B Bailey, Fenimore

Others present were Richard M Fletcher and A R McDonald Chicago

The conference was called to order at 10 a m by the chairman Dr Arthur Dean Bevan Chicago, who delivered the following address

CHAIRMAN'S ADDRESS

The Council on Medical Education of the American Medical Association has invited you to this third annual conference to discuss the subject of medical education in America and to ask your advice and cooperation in the effort to elevate the standards of medical education in this country

We welcome you to this conference and thank you for your presence in the name of the American Medical Association

It would seem well first to review briefly the work of the Council as presented in the reports of the last two annual conferences and to present to you fully the work of the past year In 1904 the Council on Medical Education was created by the American Medical Association to act as its agent in the efforts to elevate the standards of medical education Its functions are to make an annual report on the existing conditions of medical education and to make suggestions which may lead to the gradual improvement in these conditions

THE PREVIOUS HANDICAP

The work of the committees on education which, before 1904, had undertaken this task had not been as satisfactory as was desired, chiefly because new men were appointed on this committee each year and this short period was not sufficient time to enable the members of the committee to become familiar with the enormous and complex problems presented by the medical laws of fifty states and territories, by the widely varying conditions found in the different sections of our country and the even greater differences in standards of both preliminary requirement and medical curriculum demanded and offered by more than one hundred and fifty medical schools

These committees worked under the disadvantage of having no permanent organization no permanent headquarters no permanent secretary and no appropriation without which an extensive investigation was impossible

The Council on Medical Education was created with the purpose of overcoming some of these disadvantages It is the desire to make it a permanent national bureau on medical education, with permanent headquarters, with a trained clerical force in charge of

work which is required in order to collect and disseminate the facts in regard to the medical laws of more than fifty states, the results of examinations before more than fifty state licensing boards and the licensure each year of more than seven thousand physicians, the work of the more than one hundred and fifty schools, and we hope before long the facts in regard to the preliminary education of each matriculate in medicine.

Such a national bureau on medical education can have no legal powers. It can not be too often repeated that the legal power to control medical practice rests, and should always and will always rest, in the hands of the state licensing boards.

THE NEED OF A NATIONAL BUREAU

Nevertheless it is clear that a national bureau of medical education is a necessity, and it is also clear that the publicity given to the evidence which such a bureau can collect may be of great service in securing needed reforms.

The Council felt from the beginning that it was of the greatest importance to secure the cooperation of those most influential and most interested in the matter of medical education, and with that end in view established an annual conference on medical education at which it could present to the representatives of the state boards and all specially interested the results of its year's work and confer with them as to the best line of future action.

The first annual conference was held in Chicago, April 20, 1905. At this conference the questions of preliminary educational requirement, the medical curriculum and the relation of the college of liberal arts to the medical school were discussed. As a result of this conference the Council formulated an ideal standard to work for in the future and a minimum standard for the time being. This last you are all familiar with. It is briefly a preliminary education sufficient to enable the student to enter the freshman class of our recognized universities and the passing on this education by a state official and the graduation from an approved medical school, requiring a four year course of not less than 30 weeks, 30 hours each week, each year, and finally the passing of an examination for licensure before a state board.

May 12, 1906, the second annual conference was held, at which probably the most important subject was the report of the standing of medical schools based on the showing made by our graduates before state boards. The medical schools were divided into four classes. Table 1, with less than 10 per cent rejections. Table 2, with from 10 to 20 per cent of rejections. Table 3, with more than 20 per cent of rejections, and Table 4, an unclassified list of schools which did not offer sufficient data to enable them to be classified. These tables will be published each year and have, it is believed, been of much service in elevating medical standards.

At the last conference an important committee was appointed, with instructions to report at this conference, the committee on the question of giving credit for subjects required in the medical curriculum taken in colleges of liberal arts. Since the last conference at a meeting of the Council, it was unanimously agreed to recommend that by 1910, in addition to the preliminary education sufficient to enable the student to enter the freshman year of our recognized universities, that one year of physics, chemistry and biology and one modern language, preferably German, be required before the student can begin the study of medicine, a committee to present this important subject will report at this conference.

Probably the most important work undertaken by the Council during the past year has been the personal inspection of the medical schools of the United States to ascertain the exact character of their work and the attempt to classify these schools and mark them on a civil service basis. This has been a large and onerous task, the country was divided into sections and the 160 schools visited by some member of the Council or by the secretary in most instances by both the secretary and some member of the Council.

This work has been of much value and has enabled the Council to form a better idea of existing conditions of medical education than could be obtained in any other way. The schools were marked as an individual might be in taking a civil service examination.

The following ten points making a possible 100 were taken into consideration:

- 1 Showing of graduates before state board examinations
- 2 Requirements and enforcement of satisfactory preliminary education
- 3 Character and extent of college curriculum.
- 4 Medical school buildings
- 5 Laboratory facilities and instructions
- 6 Dispensary facilities and instruction
- 7 Hospital facilities and instruction
- 8 Extent to which first two years are officered by men devoting entire time to teaching and evidences of original research work
- 9 Extent to which the school is conducted for the profit of the faculty directly or indirectly rather than teaching
- 10 Libraries museum charts etc.

These marks were obtained from a full report furnished by the school and also from personal inspection covering these points.

We have then arranged the school into six classes A, B, C, D, E and F.

The A class, being from 90 to 100

The B class, being from 80 to 90

The C class, being from 70 to 80

These three classes above 70 form an accepted list and it is recommended that the state boards recognize these schools as being up to standard.

The D and E class, being from 50 to 70

It is believed that these schools should be recognized, provided that they make improvements, which will bring their work up to the necessary grade of 70.

The F class, being 50 and below

It is believed that these schools should not receive the recognition of the state boards.

In making this inspection the Council has been exceedingly lenient in marking the poorer schools. It believes that this first report should be presented to the state licensing boards and to this conference and should not be published with details at present, that a minimum standard or what shall constitute a recognized medical school be agreed on and that the schools below this standard be given a reasonable time to bring themselves up to this acceptable standard. In case they do not, their standing should be published and they should no longer be recognized by the state boards.

There are in this country 160 medical schools, about as many as there are in Great Britain, Germany, France and Austria combined. The schools in this country represent all grades, from the very highest, as high probably as those of any country in the world, to the very lowest, a number being little better than diploma mills. On this inspection we have found schools which are absolutely worthless, without any equipment for laboratory teaching, without any dispensaries, without any hospital facilities, some which are no better equipped to teach medicine than is a Turkish bath establishment or a barber shop. Many of them are little more than quiz classes, in which men are drilled for the purpose of passing state board examinations. Some of the schools which we inspected are conducted by men in good standing in the profession, but in about the way that schools were conducted 25 or 30 years ago, simply didactic lectures and quiz classes without any proper laboratory or clinical facilities, and some of these men apparently do not realize the very bad work they are doing in the light of modern medicine.

I desire to present a few facts shown by this inspection.

1 Of the 160 schools, 81 received markings above 70, 47 markings between 50 and 70, 32 below 50.

2 It was clearly shown by this inspection that medical schools conducted solely for profit are a menace and should not be recognized.

3 Night schools attempting to educate a student in the hours from 7 to 10 p. m., usually after the student has devoted his day to some occupation in which he earns his living should not be recognized by any state board especially when it is found in the good schools that four years of nine months six days in the week from 8 a. m. to 5 p. m. is barely sufficient time to devote to a medical course.

4 Many schools are conducted for the purpose of preparing a student to pass a state board examination and not with the object of making him a competent practitioner.

5 A student can be prepared in a quiz class in a comparatively short course to pass a written examination before a state board and yet be absolutely ignorant of laboratory work, dispensary or hospital work and utterly incompetent to begin the practice of medicine. This fact shows the necessity of inspecting the schools as to the actual character of their work of making the written examination very practical and of including a practical examination in the laboratory and possibly later on patients in the state board examination for licensure.

6 The most important fact brought out in this inspection is this: In this country we need money for medical education. It costs more to educate a medical student than he can pay in the way of fees. Medical education must secure state aid and private endowment.

7 Every state university now in existence or established later should have a strong liberally supported medical department. No better investment can be made by any state than the establishment and support of such a medical department. Such a department at least the clinical years should be in the largest center of population in the state and in close touch with the various departments of the state board of health.

8 The public must be taught the necessities and the possibilities of modern medicine and philanthropists shown that medicine well deserves the same support that has been given to theology to colleges of liberal arts, to libraries etc. Philanthropists will not endow medical schools which are private corporations and conducted for profit. Such schools should change their organization so that they can ask for and secure necessary endowments.

9 It is in the power of the state boards and the organized profession to place American medicine on an acceptable plane.

10 Already about 50 schools have agreed to require by 1910 or before one year of university physics chemistry and biology and one language as a preliminary education before matriculating in medicine.

11 It is necessary to agree on a standard of what shall constitute a medical college in good standing. It is a result of this conference the delegates from the state boards agree to require within a reasonable time the following standard or our medical schools: we should soon place ourselves on a plane equal to that of any country in the world.

(a) Preliminary education sufficient to enter the freshman class of our universities plus after a date to be agreed on one year of physics chemistry and biology and one modern language. This preliminary education to be passed on by an officer selected by the state licensing board.

(b) Two years of study largely laboratory work in anatomy, physiology pharmacology and pathology in well equipped laboratories officered by trained men devoting their time to the subjects.

(c) Two years of clinical work largely in dispensaries and hospitals the dispensary material in the proportion of at least 10,000 per year for 100 students in the senior class and the hospital in proportion to the daily average of 200 patients to 100 students in the senior class.

(d) The curriculum and character of both laboratory and clinical work to be satisfactory to the state licensing board which shall inspect the same each year.

If the state boards represented at this conference will unite to secure these requirements and notify the schools that unless they come up to this standard by a date to be agreed on that they will not be recognized we shall take the greatest step forward that has ever been made in medical education in this country. What the members of this conference agree on will not be legally binding on any state board or any school but it will be of great weight because it will ultimately be agreed to by the majority of the state boards and no school can continue to exist in defiance of the rulings of any considerable number of state boards.

Our inspection has shown that there are a number of schools which have no equipment to teach medicine no possible right to teach medicine nor to claim recognition. It has shown that there are a number of other schools that are deficient and these should be urged to secure proper equipment and to come up to a standard sufficient to secure general recognition.

This work shows the necessity of a system of annual in-

spection made by the state boards, possibly jointly with a committee from the Council on Medical Education, so that the results of the entire country can be compiled and furnished to each state board as an official list of colleges worthy of recognition.

As a result a number of schools will consolidate, as they have already done in Kansas City, Louisville, Columbus and other cities, a number of proprietary schools which are conducted for the purpose of profit, are in fact conducted at a loss to their faculties and many of these will go out of existence.

Instead of 160 schools as we now have, we should probably have less than 100 schools which could secure the general recognition of the state boards. And these schools we must unite to strengthen. We must secure for them state aid and private endowment, we must start an active, organized propaganda for money for medical education, we must enlist in this service the local and state medical societies, the state licensing boards, the national medical associations, individual physicians and citizens of influence and we must make these efforts permanent and continuous. We must make for medicine in this country of great wealth and great population and of high average intelligence the place which it deserves.

SECRETARY'S REPORT

At the conclusion of the chairman's address, the secretary of the Council, Dr. N. P. Colwell presented a report covering the work of the past year.

Mr. Chairman and Gentlemen:—The work of the Council on Medical Education for the past year is as follows:

INSPECTION OF MEDICAL COLLEGES

In order to obtain a more accurate knowledge of conditions under which medical schools are working and of the laboratory and clinical facilities held by each college for teaching modern medicine the Council had one or more representatives visit each of the 160 medical colleges in the country. This was supplemented by obtaining written reports from the colleges.

In this research the Council has endeavored to treat all colleges alike, making allowances for the differences between the various schools of medicine feeling that where the college upheld proper standards of preliminary education, offered good courses in the fundamental branches of medicine and had a fair amount of clinical material the minor differences in treatment could be well ignored. Two reputable practitioners of any one school of medicine will probably differ fully as much in their methods of treatment when in actual practice as will practitioners of two different schools of medicine.

In classifying the colleges every detail has been carefully studied. The size of the city where the college is located as well as any and all special conditions, such as state hospitals etc. whereby clinical material is made available were inquired into. The college buildings were considered with regard to their number, size, condition, arrangement, proximity and utility. Hospitals were also considered care being made of the number of beds, the extent to which students have access to the premises and control of the college. Dispositions have received proper attention—none being made in regard to the rooms, equipment, number of patients, number of visits by the students and nearness to the college. Each subject of the college curriculum was individually studied as to the fundamental branches, none being made of the laboratory and equipment of laboratory, the presence of paid or unpaid students devoting their entire time to instruction and research and for the clinical branches the amount and variety of clinical material available to teach the subject under consideration.

The supply of charts, models and microscopes were particularly inquired into and at the same time the size of the library and the museum were made known. Careful notes regarding the character and extent of the college curriculum and the methods of teaching of each college. The same of course were not obtained from every college. The results of the inspection of each school. The

each college before state examining boards was naturally taken account of. College announcements were carefully reviewed and a careful comparison made with the facts learned from the actual inspection. The character of the men composing the college faculty was considered, every evidence of activity was noted and due credit given where good, honest work was being done. In fact, care was taken to get every fact available that would give an accurate knowledge of what each college was and the kind of work it was doing.

In order to properly credit each school the data collected was grouped under ten different heads, these being so selected that they might have equal weight and, therefore, be marked on the scale of 100. An average taken then represented the standing of the school. The ten heads are as follows: (1) The successes of graduates of the school before state examining boards, (2) the question of requirement and enforcement of satisfactory preliminary education, (3) the general character and extent of college curriculum, (4) the medical school buildings, (5) laboratory facilities and instruction, (6) dispensary facilities and instruction, (7) hospital facilities and instruction, (8) extent to which the first two years are officered by men devoting their entire time to teaching and the evidences of original research, (9) extent to which the school is conducted as an institution for teaching medicine, rather than as a means for the profit of the faculty, directly or indirectly, and (10) the owning of a library, museum, charts, models, stereopticons, etc. The result from this research is as follows: Of the 160 schools, 81 or 50.6 per cent, were above 70, 47, or 29.4 per cent, were between 50 and 70, while 32, or 20 per cent, were below 50.

STATE BOARD EXAMINATIONS

A year ago at our conference a classification of the medical schools was made based on the state board examinations for 1904. It will be remembered that 47 schools received less than 10 per cent of failures, 27 were between 10 and 20 per cent, and 38 had more than 20 per cent. There were 37 schools in regard to which there was insufficient data to permit of classification.

With the report of the state board examinations for 1905, which was published in THE JOURNAL of the American Medical Association, Aug. 25, 1906, another classification was made resulting in 45 schools having less than 10 per cent. of failures, 22 schools with between 10 and 20 per cent, and 40 schools above 20 per cent. There were 46 schools in the unclassified list.

By adding together the figures for 1904 and 1905, we get sufficient data to reduce the unclassified list to eight colleges, thus allowing us to classify 135 schools on the basis of state board examinations. The result has been 41 schools having less than 10 per cent of failures, 40 schools having between 10 and 20 per cent and 54 schools having over 20 per cent.

	Less than 10	10 to 20	Above 20	Unclassified	Total
1904	47	27	38	37	149
1905	45	22	40	15	122
1904-5	41	40	54	8	143

For the years 1904 and 1905 the colleges can be further subdivided as follows, omitting the eight unclassified:

Less than 10 per cent of failures	41
Between 10 and 20 per cent	40
Between 20 and 30 per cent	16
Between 30 and 40 per cent	19
Above 40 per cent of failures	19
	135

As has long been recognized, the weakest part of our system of medical education to day is the low standard of preliminary requirements. There was a time, doubtless, when low standards were excusable, but now when we consider the large number of schools and colleges which offer abundant opportunities to any one who has ambition enough to secure a liberal education whether he has ready money or not there is scarcely any excuse for not requiring a fair standard of preliminary education. There are still a number of schools where no attention apparently is paid to the students' entrance qualifications.

The weakest point in the equipment and teaching facilities of medical schools is, naturally the lack of laboratories and equipment for the work of the first two years of the medical course or as they are often called, the fundamental branches. The need of good, well equipped laboratories, as well as having them officered by trained instructors paid to devote their entire time to teaching and research naturally makes this part of the medical course the most expensive. The teaching of the fundamental branches does not carry the advantage to the practicing physician which is found with the clinical branches, therefore it is difficult to get good men to devote their time to these branches unless they are paid definite salaries. A few schools were found which were weak in this part of the course although strong in clinical facilities.

Some schools are not developing the college dispensary as they might. Where good quarters have been provided for this department and good men placed on the attending staff, a larger attendance is invariably the result. Some schools situated in large cities, where ample clinical material could be had are failing to take advantage of it. Others with abundant means at their disposal lack the activity in medical teaching and research which they might have.

Of course the medical schools need money and all degrees of such need are to be seen. Many schools are dependent solely on the fees of the students to cover the teaching expenses. Some are keeping the teaching expenses within the amount received and are therefore quite deficient in equipment and facilities for teaching modern medicine. Some schools however which although practically depending on students fees are manned by faculties who not only spend their time and energy in teaching without pay but have stood by the school with a devotion most praiseworthy, this being an encouraging fact in medical teaching of to-day. The development of some of these schools even with the small amount received from students fees has been remarkable. Some have fixed high standards and held to them even though these standards have reduced the number of students and thereby reduced the financial income of the school.

The past few years has witnessed the expenditure of a large amount of money for medical education. New buildings with spacious laboratories and elaborate equipment were to be seen in all sections of the country. Medical education is beginning to attract the attention of men of wealth to its needs and endowments will follow sooner or later. State legislatures are more readily making appropriations for the development of the medical departments of state universities. From the financial point of view there is reason to believe that a new era is dawning for medical education.

A few important mergers have taken place during the past few months—at Louisville Ky where four schools merged into two, and at Columbus, Ohio, where the two colleges merged into one. Combinations at two or three other points also are in prospect. There are still other places where much better medical education could be given if two or more schools would join hands thereby creating one strong school from two or more weaker ones.

The work of the Council in an effort to secure the adoption of the standards recommended by the American Medical Association

education has had gratifying results. During the latter part of last June a letter was sent to each medical school of the country clearly stating that portion of the American Medical Association's ideal standard relating to the preliminary year in physics, chemistry, biology and languages, and asking whether the faculty of the school would be willing to adopt this as a requirement to apply to all students entering after Jan 1 1910. At that time only seven colleges in the country were requiring one or more years of work in a college of arts for admission. There are now 46 medical schools, which either already require one or more years of work in a college of arts or have voted to require this preliminary year in physics, chemistry, biology and languages by Jan 1, 1910. There are at least 10 other colleges still to be heard from which will probably make the same requirement. Of the 46 schools named at least 19 colleges have already voted to require at least two years of preliminary work in a college of arts, and 8 others intend to make two years their minimum requirement, although the date for the requirement of the second year has not been definitely determined. On the list are to be found a few weak schools, but the great majority are those which can be fully depended on to live up to their requirements.

YEARS IN A COLLEGE OF ARTS REQUIRED FOR ENTRANCE

The following medical colleges either already require as a prerequisite to the study of medicine, in addition to a four year high school education or its equivalent, one or more years in a college of liberal arts, or have adopted the requirement of a preliminary year to include the subjects of physics, chemistry, biology and one language, to become effective on or before Jan 1 1910.

Practically all these schools have expressed their intention to require that the year in physics, chemistry and biology be taken in a college of arts.

LAWS GOVERNING MEDICAL PRACTICE

The progress toward securing high standards in the various states through the activity of the examining boards has been very encouraging. Many states have secured new laws or important amendments, resulting in more uniform and higher standards. A year ago 13 states still allowed non graduates to obtain the license to practice medicine. Of that number the examining boards of two of these states, Oregon and Hawaii have recently established the graduation requirement by board rulings, being legally authorized to do so. Of the other eleven states, however, amendments to the state laws were necessary. Efforts have been made to secure these amendments by practically all, resulting successfully in Colorado, Missouri, New Mexico, Tennessee, Texas and West Virginia. The number of states allowing non graduates to secure license has, therefore, been reduced to 5, these being Alabama, Arkansas, Massachusetts, Mississippi and Rhode Island. A report received is most favorable that the amendment will be secured in Alabama.

Delaware secured an amendment requiring that applicants must have had four years of study in a recognized medical school leaving only one state, Georgia, which only provides for a three year course. Two states, Illinois and Minnesota, have raised the standard of preliminary education above that of a four year high school education. After Jan 1, 1910 Illinois will require that all students matriculating in medicine must have had one year of nine months to be devoted to the study of physics, chemistry, biology and one language. Minnesota has secured an amendment to their law requiring hereafter that all matriculants in medicine must have at least two years of work in a college of liberal arts. One other state, Connecticut is trying to obtain requirements in addition to the four year high school education. Similar action on the part of other state boards will hasten the time when the standards of medical education in this country will be as high as those of other leading nations. The requirement of an additional year of preliminary education by state examining boards will be an added encouragement to the 45 colleges which of their own volition have adopted this standard.

Greatly improved medical practice acts or important amendments have been secured recently in California, Delaware, Minnesota, Missouri, New Mexico, Tennessee, Texas, Utah, Vermont, West Virginia, Wisconsin and possibly in other states which have not been reported to us. Reports show that new practice acts or amendments are being urged in Alabama, Colorado, Connecticut, Michigan, Ohio, Pennsylvania and New York with promise of success in the majority of cases. Important board rulings have been voted by a number of state boards at least in Colorado, Oregon, Hawaii, Illinois, Michigan, Minnesota and New Hampshire. Probably no time has ever witnessed so widespread an effort for better laws. The tendency is rapid toward more uniform and higher standards.

BOOK OF LAWS

The changes in medical practice acts will be carefully followed up and published in the Book of Laws, a new edition of which is issued about every four months. Registration requirements in foreign lands, as well as standards of medical education are also being given in this book so far as they can be ob-

tained Reports for all changes of the past few months have probably not been received, therefore, we particularly request of the examining boards that notice be sent us of any changes or additions to the laws as presented in this book.

RECIPROCITY

At the last session of the American Medical Association in Boston the work formerly devolving on the Committee on Reciprocity was turned over to the Council on Medical Education. Since the extension of reciprocity depends so much on the securing of equally high standards of medical education and licensure, the Council has bent its energies chiefly to obtain such standards, merely watching and noting the progress of the reciprocity movement. In practically all of the new practice acts secured during the past year and in a number of amendments reciprocity has been provided for. On the whole, the justice of reciprocity is being recognized and the movement favoring it is spreading. Statements showing any licenses issued under the reciprocity clause have been received from 21 different states. No statement has been obtained from New Jersey. The list of states and number so licensed in each is as follows:

Delaware	5	Nebraska	56
District of Columbia	11	New York	11
Georgia	6	North Dakota	21
Illinois	43	Ohio	6
Indiana	21	South Carolina	4
Iowa	67	South Dakota	29
Kansas	36	Texas	8
Kentucky	6	Vermont	4
Maryland	6	Virginia	16
Michigan	61	Wisconsin	61
Minnesota	42		

Or a total of 529. A table which shows at a glance just what states reciprocate and on what basis is published regularly in the Book of Laws and revised with each edition of that book. (See Laws, pages 115 116 and table.)

WORK OF STATE COMMITTEES

State committees on medical education have now been appointed in 45 states, or in all states except Alabama, Arkansas, Nevada, South Carolina, Tennessee and Georgia. These committees have done good work in several instances, having studied local conditions extensively and made splendid reports to their state associations. Particularly was this true in Illinois, Louisiana, Maryland, Minnesota, Missouri, New York, Texas, Virginia and West Virginia. Doubtless other committees have been active also but have not reported to us.

Though these committees it is hoped that each state medical society will be kept fully informed as to how the standards in their own state compare with the standards throughout the country. These committees can do much to help secure the adoption of the American Medical Association standards in all states by securing for the state-examining boards the solid backing of the state medical societies.

In conclusion, the work of the Council for the past year may be briefly outlined as follows:

(a) Collecting, tabulating and publishing the results of state board examinations showing the successes and failures of the graduates of the various medical colleges.

(b) Securing, tabulating and publishing statistics regarding medical students and medical graduates in the United States.

(c) Compiling and publishing abstracts of laws and board rulings governing medical licensure in the United States.

(d) Cooperation with state examining boards, state committees on medical education and with medical colleges in an effort to secure the adoption of the standard of medical education adopted by the American Medical Association.

(e) Collecting of more accurate information regarding medical colleges and their surroundings particularly concerning the staff history, buildings, hospitals, laboratories, dispensaries, equipment, college year, etc. This was obtained by securing reports as well as by a systematic inspection of the colleges.

(f) Keeping informed regarding proposed changes in medical practice acts and rendering any assistance possible for the obtaining of advance legislation.

(g) Keeping informed regarding reciprocity and securing

from the examining boards reports of licenses issued on that basis.

(h) Collecting from all available sources information bearing on medical education and furnishing it wherever it might be of service. Much has been published in the department of THE JOURNAL, entitled Medical Education and State Boards of Registration.

N. P. CORWELL, Secretary

(To be continued.)

AMERICAN GYNECOLOGICAL SOCIETY

Thirty second Annual Meeting, held at Washington, D. C., May 7, 9, 1907

The President, DR. CLEMENT CLEVELAND, New York, in the Chair.

Officers Elected.

The following officers were elected to serve during the ensuing year: President, Dr. J. Montgomery Baldy, Philadelphia, vice presidents, Drs. J. S. Stone, Washington, D. C. and Malcolm McLean, New York, treasurer, Dr. Charles P. Noble, Philadelphia, secretary, Dr. J. Riddle Goffe, New York (re-elected).

The next meeting will be held in Philadelphia on the fourth Tuesday in May, 1908.

Metastatic Carcinoma of Tube and Ovary in Cancer of Cervix Uteri

Dr. FRED J. TAUSSIG, St. Louis, said that mild chronic, inflammatory conditions of the tube and ovary are frequently met in cancer of the cervix. Whether this is merely a coincidence or not he is unwilling to say. On the other hand, cancerous metastases in these organs are extremely rare in cervical cancer. In fact, he can find no record of such metastasis in an operable case. In carcinoma of the body of the uterus, however, they are not infrequently seen in tube or ovary, or both. Hence it seems logical to advise the removal of both tubes and ovaries in every case of cancer of the body. If, however, the patient is still five or ten years from the time of the menopause, and the site of the tumor be in the cervix, the saving of one ovary is attended with practically no risk to the patient and may relieve her of the disagreeable symptoms of the premature menopause. Since this can be done without interfering with the complete removal of the lymphatics directly tributary to the cervix, he believes it logical to leave one ovary or a portion of one ovary, in every operation for cervical cancer in a woman under 40 years of age.

DISCUSSION

Dr. J. WESLEY BOVÉE, Washington, D. C. said metastases in cancer of the uterus are by no means common and that, as the disease spreads, metastases occur. This emphasizes the fact that in the case brought to the attention of the gynecologist he is helpless in the treatment of cancer of the uterus, that in the cases in which the conditions ordinarily offer great hope of success we will find that metastases occur in these structures which are not removed, the result being that cancer recurs or continues unsuspected. At best, the treatment of cancer of the uterus is not hopeful notwithstanding the claims of radiographers and the demonstrators of radium, etc., and those who do the most radical surgical operations. He is not prepared in the present light of the surgery of cancer of the uterus to accept the suggestion of the essayist that it is safe to leave a portion or even one ovary in extirpating a cancer of the uterus. His own conviction is that the operation should be as radical as it can be consistent with saving the life of the patient.

Dr. LATHORN SMITH, Montreal, reported a case of cancer of the cervix in which operation was done early by another surgeon with every possibility of a complete recovery of the patient yet this woman came to him a year later with two distinct masses in the ovaries which could be felt readily. He considered it too late to operate. This case made such an impression on him that ever since, when doing vaginal hyster-

ectomy, he always removes the tubes and ovaries. He does not think it safe to leave an ovary or a piece of an ovary, when there is such a tremendous risk of recurrence.

DR. REUBEN PETERSON, Ann Arbor, Mich., agreed with Dr. Boyce against leaving one ovary or a part of one ovary in the operation for cancer of the uterus. This is a step backward, and is not in accordance with progress that has been made in the last ten years in the treatment of cancer of the uterus. He is not convinced that the leaving in of one ovary, after the removal of the uterus, helps the patient so far as the menopausal changes are concerned. He has been unable to see much, if any, difference where an ovary has been left in, and where it has been removed, after the removal of the uterus for cancer.

DR. WALTER M. CHIPMAN, Montreal, doubts whether it is a wise thing to leave even one ovary, or even a part of one, after the removal of the uterus for cancer, no matter where the cancer is situated. While it is true that the ovary is not in the direct path of the lymphatic distribution of the pelvis, yet so great and so rich is the anastomosis that he thinks the leaving in of ovaries must always be risky.

DR. FARRIS said he anticipated that most of the speakers would disagree with him as to the advisability of leaving a portion of an ovary in the class of cases he discussed, but he believes that this procedure is not at all unsafe, and it seems to him that it is just as logical to advise the removal of the appendix as it is to advise the removal of the other ovary. The appendix is a useless organ, the ovary—at least, in the opinion of some—helps to make the menopausal disturbances less severe in women under 40 years of age, if left.

(To be continued.)

THE MEDICAL JURISPRUDENCE SOCIETY OF PHILADELPHIA

Meeting held April 12, 1907

The President ADOLPH FICHOLTZ, Esq. in the Chair

The Pathogeny of Crime

DR. ARNOLD LORAND, Carlsbad, in his recent lecture before this society took high ground and made a number of statements likely to provoke deep interest in all circles where it is common to face truth and find remedy for evil rather than shirk the real and weakly accept the coward dictum that whatever is right. Broadly speaking, Dr. Lorand held that the two barriers protecting the individual against crime or a criminal career are in active and free will power guided by a sound reasoning power. To see right and to be able to do it—to recognize wrong and have power to refrain from its practice here is the heart of his pathogeny of crime. And this position he justifies in the following way: When a man has free will power he is able to control his passions, when possessed of sound reason he can distinguish between right and wrong.

The operation of the thyroid gland plays an important part in the pathogeny of crime. When the thyroid is removed there is a resulting effect on the nervous system. Mentality undergoes a change. In myxedema there is found melancholia. In myxedema there is not free will power and the reason is not perfect. Moreover, these persons have delusions of persecution. Insanity and criminality stand in close relation, the difference being only one of degree. In exophthalmic goiter where a condition of exaltation bordering on insanity is found there are often symptoms of hysteria and neurasthenia. Hysteria stands in close relation to criminality. Chloroform also excites the function of the thyroid gland. Alcohol, too, acts on the thyroid gland, producing increased activity with a condition like drunkenness. Further he said that infectious diseases bring about an alteration of the thyroid gland and through such alteration a condition parallel to that underlying insanity and criminal acts may occur. Reference was made to the well known fact that the sexual glands and the thyroid gland stand in close relation. Each time the sexual glands are altered the thyroid gland is also altered. In puberty this is evidenced by the swelling of the

thyroid gland, with consequent alterations of mentality. This has been illustrated by the wandering away from home of young girls. Then, too, alterations in mentality are noted during pregnancy, bringing to pass a weakening of the will and a diminution of the reasoning power. Here it was noted that injection of the extract of the ovaries or testicles acts as a toxic product, further, that castration in man produces melancholia, that after castration in women nervous symptoms invariably take place. This was considered important to bear in mind because in deciding whether a woman has committed criminal action the question must always be considered whether she has been in physiologic or a pathologic condition. Reference was made to a case of kleptomania in a woman who was naturally honest, but every time she was pregnant she would steal. Dr. Lorand said that he would not put such a woman in jail.

After every hyperactivity of the sexual glands there is exhaustion. In the interest of the procreation of the race virtue is a necessity in woman. Hysteria was said to be a condition found in connection with alteration of the sexual glands. In man the testicle plays as great a rôle as the ovaries in woman. This is shown in the mentality of the eunuchs. No eunuch was ever a great man. In old age are seen senility and avarice.

Most courts in Europe, it was said, accept responsibility before the law only when puberty is established. The conception of right and wrong is not the same in a person of 16 or 18, because the testicles are not descended. Dementia præcox is a condition in which crime can be committed easily.

Attention was called to the fact that there is such a thing as exposure to crime by imitation. Experiments show that monkeys, apes and men imitate because they do not know by reasoning whether an act is right or wrong. The suggestion is made that one barrier against crime is to prevent the children from attending cinematograph shows, for it is a well known circumstance that children born of parents who are hysterical or neurasthenic when they see criminal acts are inclined to commit them. Of 173 persons in France who had been beheaded only 2 had not seen an execution.

There is no doubt of the importance of the part played by the ductless glands in insanity, and, coincidentally, in crime. Therefore, alterations of the ductless glands should be inhibited. If the thyroid glands of the parents are altered, the thyroid glands of their children will be altered, too, that is, be differentiated from the normal. It should not be forgotten that in alcoholism there is degeneration of the thyroid gland, also in syphilis and other infectious diseases and that the children of such persons must reap the harvest either in the form of thyroid degeneration or congenital atrophy of the thyroid gland.

Another fact of the first importance is that crime is most common among children of alcoholic and syphilitic persons because these children are born in a condition of congenital myxedema and are lacking reason and will power. Dr. Lorand thought that all would agree to the proposition that it is best for the state to take children of criminals away from home and put them into schools where they will be educated at the expense of the government. This would be true economy for it will cost far more to allow such children to grow up criminals and for years to occupy our jails. While education is a preventive of crime, hand in hand with education must go a realization of the necessity of aid from religion and from reason. Religion is, and must be the basis of every government and every state. Without religion a country can not stand. A criminal court is not sufficient; it is only a restorative or corrective, it is never a creative force. Education is a necessity because the educated man will reason himself into a belief in the wisdom of obedience. Obedience will teach exercise of will power.

Criminality appears to be larger in the United States than anywhere abroad because lack of self control is a national characteristic and there are here few aids to self control, few public lessons in the habit of obedience. Lacking enforced military service the young men do not have the training and discipline enjoined by the men of Europe. The young man is not taught to subject his own will to the will of others. Sons

of the wealthy class are chronic idlers, they run naturally to sexual excess, there follow, inevitably, alterations of mentality

As to the mental condition "dementia Americana," Dr Lorand does not admit its existence. The condition suggested he would term "dementia plutocratica." This condition, however, he declares, is not essentially American. It is only more common in America because America is richer than other nations

In his opinion, specialists in neurology should be constantly in the service of the government. In difficult cases there should be a third man. It should be remembered that the highest wisdom suggests that in the treatment of criminals the questions be asked, Is punishment the real treatment of disease? What are the purposes of punishment? The first purpose is the protection of society. All are agreed that vengeance should not be the sole guide. Dr Lorand suggested to put criminals in a colony where they can be taught to raise cattle, chickens, flowers and vegetables. This would be a wiser policy, and would better safeguard the state than to imprison them, for when such a term of detention has expired the men come out with no taint on them, and they can be made useful members of society

To sum up the situation, excess or deficit in working power of the thyroid gland or other ductless glands may develop into an abnormal condition which makes inevitably toward insanity, insanity makes, by normal progress, through advancing forms of the imagination coincident with a weakening of the will, toward crime, crime makes for the destruction of the state and the end of civilization. It would thus appear that the safety of society rests on the maintenance of normal conditions in this gland which is so potent in its influence on the moral as well as the physical life of the individual. In short, crime has a basis in a physical fault, the correction of crime is to be sought in the correction of this physical fault rather than in vengeful or isolating forms of punishment inflicted by a hard and fast rule on the individual criminal. Sanity and virtue are synonymous terms—insanity and crime interchangeable synonyms

DR. CHARLES DE M SAJOURS agreed with the views of Dr Lorand, believing that in his presentation of the subject there are the fundamental principles of a proper, fair and just interpretation of many conditions confronting the courts. He feels that the ends of justice would be served if many of those tried by courts of justice were examined physically and treated according to the findings

DR. F. X. DEROUX agreed with the general trend of Dr Lorand's address. He feels that the present attitude toward crime is the same as that toward the insane something over a hundred years ago. If the laws could accept the idea of lessened responsibility and deal with crime in accordance with that, he sees that a great step in advance would be made. He agrees with Dr Lorand that crime should be dealt with from the standpoint of treating the criminal, and that little or nothing can be accomplished by confining him for a given number of months without occupation. He should be put under conditions in keeping with simple physiologic living. Segregation should not be for months or years, but should be dependent on the change in condition. This he regards as the humane view, and expresses the opinion that there will be a change in the oversight of the criminal quite as radical as that seen in the care of the insane

DR. ALFRED GORDON felt that Dr Lorand's ideas were based on scientific principles and deep scientific knowledge. He agreed with Dr Lorand in the majority of his propositions. In the matter of medicolegal testimony, his ideas are absolutely identical with those of Dr Lorand. A case was cited in which in giving expert testimony he had not been allowed to enter into the details which, in his opinion, lessened the man's responsibility. He believes that if a man is considered an expert, he should be allowed to submit to the judge and jury details of family history and matters of medical knowledge. He believes that the end of justice should be not alone to prosecute the criminal, but to study him for the purpose of preventing crime

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Semi Centennial Celebration of Its Founding, held
May 9 11, 1907

The President, DR. W. M. L. COPLIN, in the Chair

The Pathological Society of Philadelphia commemorated the fiftieth anniversary of its founding May 10 and 11, 1907. Exhibition meetings began Thursday evening, May 9, and were continued until Saturday, May 11. The formal exercises were opened by the president, Dr. W. M. L. Coplin of Jefferson Medical College in the Mutter Museum, College of Physicians, at 10 a. m., May 10, when the society went into scientific session

The Role of Protozoa in Pathology

DR. FREDERICK G. NOVY, Ann Arbor, Mich., gave a history of the advances made in the study of protozoal diseases and called attention to the difficulties in determining their etiologic factors. The etiologic relationship of amebæ to disease is well established, and Novy stated that their division into a pathogenic and non pathogenic group is unwise, especially in the tropics, where the only safe hypothesis to adopt is that all amebæ are or may become pathogenic. Trypanosomal infections, he pointed out, are to be met perhaps in all parts of the world, and they have been found in so many forms of animal life that it seems as if no type of vertebrate is exempt. The experiments in regard to the relative behavior of trypanosomes and of spirochetes to a given anilin dye can not, in Novy's opinion, be accepted unreservedly as a means of differentiating species. The discovery of a trypanosome in patients ill with sleeping sickness he holds to be most important and the experiments being carried on in Central Africa by Koch on the treatment of injections of anilin compounds is to be awaited with interest. Spirochetes, the speaker believes, belong in a group by the side of bacteria, and more especially the spirilla, stating that it is impossible to trace a sharp dividing line between the protophytes and protozoans, and that one must be guided by the different relationship to recognized types. In the supposed protozoal diseases, namely—cancer, smallpox, scarlet fever, measles, yellow fever, rabies and Rocky Mountain fever, Novy urges more exhaustive work along physiologic, chemical and biologic lines unless the crucial test, that of artificial cultivation, is first realized, since morphology alone seems powerless to overcome the *impasse* in which seemingly we find ourselves to day. The mode of transmission of this group of diseases is for the most part by insects, though in some of the lower animals infection has taken place through an apparently uninjured mucous membrane. Novy believes that the insects are not only passive but active carriers of both bacteria and the protozoa, and hence the transmission of certain spirochetal diseases by ticks does not afford a serious argument against the bacterial nature of the spirochetes, and the similar rôle of stegomyia in the transmission of yellow fever does not necessarily imply protozoal organisms. He considers the evidence as being suggestive of a spirochete cause

The Dynamic Point of View in Pathology

DR. A. E. TAYLOR, San Francisco, made a plea for a more rational and scientific viewpoint of pathology. He considered pathology under three headings: Etiology, of predominant importance from the point of view of preventive medicine and a subject to which too great importance can not be attached in teaching and investigation; morbid physiology, the doctrine of the *modus operandi* of disease, and morbid anatomy, the doctrine of histologic lesions. He pointed out that the last subject has until recently greatly overshadowed the first and continues to overshadow the second, particularly in the teaching of pathology and thus secondarily in the minds of the profession. He considers this disproportionate predominance accorded to the visible lesions of disease out of all proper perspective and proportion and constitutes a bar to the development of the point of view of morbid physiology in clinical medicine. This position he attributes to the fact that physiology was for a long time largely a descriptive science mainly because the majority of physiologists were offshoots from anatomy. At the present time too emphasis is not being laid on the importance of the physiologic

chemistry to influence pathology in the direction of the dynamic point of view. In regard to practical medicine, he very aptly pointed out the importance of the dynamic point of view in research in pathology by calling attention to our knowledge of two diseases, nephritis and diabetes. He showed how in nephritis the localization of the lesion has been known from the beginning, while for diabetes none has until recent times been known, yet, we to day know much more about the actual morbid functionation in diabetes than we do in nephritis.

The Newer Pathology

DR SIMON FLEXNER, of Rockefeller Institute New York, believes that while a study of the anatomical changes introduced in cells by disease has not been exhausted and each year adds valuable stores to our knowledge of the pathologic changes underlying diseased processes, yet the most significant advances are being made by the study of the nature and mode of action of the causes of disease, and that, therefore, the hope for the immediate future lies in the further study by every means that physiologic and biologic science can supply of the infective diseases. The problems confronting the newer pathology, according to the speaker, are to determine the mode of onset, the prevention and the cure of disease. To study prevention the method of infection must first be determined. In the advances made so far, we have learned that not only is the transmission from man to man, but that the man's animal associates and enemies must be carefully scrutinized. The problem of the causation of some of the infectious diseases, namely, smallpox, yellow fever, scarlet fever and measles, Flexner stated, must not be approached from the standpoint that the infective germs of these diseases are ultra microscopic in size. The cause of disease discovered, the task of pathology, according to Flexner, is merely begun. To possess the cause is merely to be confronted with the problem of the immediate manner in which it acts on the seats of disease to produce the changes which we recognize as being pathologic. The speaker referred to the studies on immunity to bacterial infection, as removing a large part of the mystery of the so called self limiting diseases. The present problem is to work out the phagocytic doctrine of Metchnikoff, the humeral doctrine of Ehrlich and the theories of active immunity reaction in the fixed cells of the body. The most difficult problem is to determine the nature of bacterial immunity with the same success that has attended the work in the production of diphtheria antitoxin. The junction of pathology with experimental therapeutics, Flexner believes, opens up a field for interesting and profitable research for specific chemical studies. The recent study of the origin of tumors and the application of the principles gained in the study of infection and immunity in bacterial disease to the study of transplantable tumors in mice opens up wide vistas for future research, and Flexner emphasized that because of this no one is justified on account of the similarity in the phenomena to believe that tumors are of necessity caused by parasites, but rather it discloses the fact that infection and immunity to unicellular organisms are merely special cases of biologic reactions applicable to a wider and more complex series of living structures of which special instances have been found in relation to hemolysins, cytotoxins, precipitins, agglutinins, etc.

Luncheon

The morning session was concluded with this paper, after which the members entertained their guests at an informal luncheon at the University Club, at which 250 were present.

Pathology and Practice

At 4 p m in the assembly hall of the Pennsylvania Hospital in which historic building the first meetings of the society were held, Prof William Osler, University of Oxford, England was introduced by Dr Alfred Stengel, University of Pennsylvania and delivered an address. He advocated the removal of public health matters from the hands of politicians and the teaching and training of men specially in matters affecting the physical well being of the entire community. He further pointed out that the standard of medical education must be raised. He regretted the possibility for men to graduate in

this country without autopsy or hospital experience, and advocated reforms in this direction. Here are a few epigrams from Dr Osler's lecture.

With only a few drugs man can practice medicine very well
In the past fifty years our ideas have changed and we have reached a rational standpoint.
We are the teachers and not the slaves of our patients
We work by wit and not by witchcraft
Don't make promises to heal when it is impossible to heal
The highest aim is not to cure, but to prevent disease
He cures most in whom most have the greatest confidence
Give up lecturing medical students to death and make them do practical work
No one professor in medicine can teach all there is or know about everything

The banquet in the evening is mentioned under Philadelphia news this week, page 1687

AMERICAN CONFEDERATION OF RECIPROCATING, EXAMINING AND LICENSING MEDICAL BOARDS

Annual Meeting, held at Chicago, April 30, 1907

The President, DR W A SPURGEON, in the Chair, DR B D HARRISON, Secretary

The following state medical boards were represented: Indiana, W A Spurgeon, W T Gott, Michigan, B D Harrison, Ohio, H E Beebe, A Ravogh, Minnesota, W S Fullerton, Nebraska, B F Bailey, New York, C E Gorman, Massachusetts, E B Harvey, Kentucky, C A Mayer, Wisconsin, J F Stevens, P H McGovern, Utah, R J Richards, Colorado, S D Van Meter, West Virginia, J L Dickey, North Dakota, F R Smith, Idaho, W F Howard, Missouri, R H Goodier, Vermont, W Scott Nay.

Others present were A D Price, Vanderbilt University, Tenn., S C Baldwin, State Medical Society, Utah, J A Witherspoon, Tennessee, Council on Medical Education, A M A, S L Jepson, State Medical Society, W Va, V C Vaughan, Michigan, Council on Medical Education, A M A, F C Zapffe, Illinois, secretary Association American Medical Colleges, W J Means, Ohio chairman Judicial Council, Association American Medical Colleges, W B Hinsdale Michigan, dean Homeopathic Medical College, U of M, H N Ludwick, Illinois, ex secretary Wisconsin medical board, W T Councilman, Massachusetts, Council on Medical Education, A M A, A D Bevan, Illinois, chairman Council on Medical Education, A M A, N P Colwell, Illinois, secretary Council on Medical Education, A M A, L C Morris, Georgia, Southern Medical College Association, A B Bailey and A P Andrus, Wisconsin. The minutes of the Columbus (Ohio) meeting, April 25, 1906, were read and adopted.

Secretary's Report

This report stated that there had been a conservative progress of the reciprocity movement during the past year, and that this movement had assumed a well defined educational system, as well as a necessary policy of convenience in medical licensure. It called attention to the difficulty encountered from the fact that the term "medical reciprocity" was subject to an almost universal misinterpretation of its scope and intent. Medical reciprocity (a) does not mean a leveling of the products of medical registration of two or more states followed by unrestricted endorsement of medical licenses of such states, (b) but the accepting of present and future conditions of standard of two or more states and endorsement on mutually accepted products of a certain and known standard.

The only material thing accepted through Qualification 1 is the credit of the board examination and the recommendation of the reciprocating state covering moral and professional character. Under Qualification 1 the former prevailing idea that reciprocity involved the recognition of licentiates in classes as opposed to individual recognition is fast disappearing. A defective qualification, either involving preliminary or medical education, accepted in one state on account of exemptions in the law, or through error or defective administration, can not, through such state recognition, claim immunity in fulfilling the exact requirement of another state in reciprocity.

Qualification 2, which involves the recognition of the older and experienced graduate, is also fast becoming better under-

stood The material qualification involved in this form of reciprocity is contained in the following definite statement "If the practitioner, at the date of his diploma and state license obtained on the basis of such diploma, could have fulfilled the requirements of the reciprocating state at such an even date and prior to the date of the requirement of the double qualification (diploma and state board examination), and, in addition, can furnish evidence of continued reputable and successful practice, then his qualifications may be endorsed" The fact that out of some 600 licenses reported endorsed during 1906 only 60 of these are under qualification 2 demonstrates that the danger attributed to this form of reciprocity is greatly exaggerated

Since the 1906 meeting the regular board of Georgia and the West Virginia board have been admitted to the confederation, and several other boards have put into effect reciprocity agreements with other states, and other boards have where possible, extended their reciprocity agreements to both qualifications

Thirty one states now endorse licenses through reciprocity, 13 under Qualification 1 only, and 18 under both qualifications and several states are obtaining the necessary legislation covering the future endorsement of licenses under both qualifications

The report suggested the issuing of a pamphlet similar to the one issued by the American Medical Association under the title of "Abstract of Laws" The report also called attention to the want of uniformity in application forms used by the several states and suggested the continuance of the committee on forms, having in view the remedying of this defect

Licenses were endorsed through reciprocity during the year 1906 as follows

State	No I	No II	Total
Connecticut Eclectic Board	6		6
Virginia	19		19
South Carolina Regular	8		8
Indiana	12	0	12
Iowa	65	8	73
Delaware	4		4
Maryland	Not classified		26
Ohio	50	0	50
Missouri	32	3	35
Illinois	47		47
North Dakota	20		20
Wisconsin	10	12	22
Georgia Homeopathic	1		1
Vermont	3	2	5
Minnesota	40	1	41
New York	31		31
Kansas	Not classified		120
Michigan	44	17	61
	388	58	593

Advanced Standing

Discussion on this subject elicited the fact that a large number of states have the statutory requirement of "four years in a medical college" It was the consensus of opinion, therefore, that the better policy for the confederation would be to take no action whatever relative to the subject of advanced standing, but that the subject should be left to the judgment of the individual board and the limitation of its medical act

It was, therefore, moved by Harrison (Michigan), seconded by Stevens (Wisconsin), that all matter relative to advanced standing adopted at the Columbus meeting, 1906, and at all former meetings, be expurged from the minutes Carried

Attention was called by the president to the report of the Council on Medical Education, American Medical Association, relative to the result of an inspection of the medical colleges of the country by the council The result of this inspection was very highly commended by several members, and far reaching benefits were anticipated in the cause of higher standards in the future

Moved by Bailey (Nebraska), seconded by Ravogli (Ohio), that a committee of five be appointed (of which the president and secretary shall be members), whose duty it shall be to secure all data possible concerning the medical colleges of the country and to report at the next meeting of the confederation, with recommendations looking to better control of the colleges by the state in which they are situated Carried

The following were appointed members of such committee

Harrison (Michigan), Spurgeon (Indiana), Stevens (Wisconsin), Hamel (Missouri), Bailey (Nebraska)

Moved by Mayer (Kentucky), seconded by Stevens (Wisconsin), that the chairman appoint a committee of three to deliberate on and formulate a plan for more uniform legislation in respect to the powers of licensing boards in the revocation of licenses for immoral and unprofessional character Carried

The president appointed as members of this committee Mayer (Kentucky), Dickey (West Virginia), Canfield (Indiana)

Preliminary Requirements

Moved by Bailey (Nebraska), seconded by Gott (Indiana), that no change be made at this time in the standard of preliminary education adopted by the confederation at Columbus, 1906, and that a committee of three be appointed to confer with the secretary of the Association of American Medical Colleges to consider the flexibility of such standard and to report at the next meeting of the confederation Carried

The president appointed as members of such committee Harrison (Michigan), Gott (Indiana), Matson (Ohio)

Uniformity of Forms

The committee on uniformity of forms, of which Dr Stevens of Wisconsin is chairman, was continued

Officers Elected.

Dr W A Spurgeon, Muncie, Ind, a member of the Indiana State Board of Examiners, was re elected president, and Dr B D Harrison, Detroit secretary of the Michigan State Board of Registration in Medicine, was re elected secretary

The president, Dr Spurgeon, stated that he wished to have recorded in the minutes a statement of appreciation of the very valuable assistance and advice the confederation had received from the Association of American Medical Colleges and from the Council on Medical Education of the American Medical Association, and he trusted that the confederation's relations with these bodies in an advisory capacity would continue in the future as it meant much in the cause of uniformity of standards in preliminary and medical education Several other members representing state medical boards, re echoed this statement of the president

ASSOCIATION OF AMERICAN PHYSICIANS

Twenty second Annual Session, held at Washington, D C
May 7 9, 1907

The President, Dr FRANCIS P KINNICUTT, in the Chair

The Need of Perfected Organization

Dr FRANCIS P KINNICUTT, New York in the president's address chronicled the death of three members during the past year, active members Drs Stewart of Montreal and Atkinson of Baltimore and honorary member Dr Latimer of Baltimore He spoke of the discoveries of Wright and Douglass regarding the opsonic power of the blood and the need for testing the practical availability of the procedure The physician of the past and too largely of the present has been the individual, and the profession has taken no commanding position in municipal and state affairs In those affairs they are now needed

Connections of Occipital Lobes and Present Status of Cerebral Visual Functions

Dr ADOLF MEYER, New York, gave a lantern slide demonstration of specimens from cases showing that the optic radiations can be much further subdivided than has been done Among the points illustrated were the isolation of the geniculate calcarine tract the afferent character of the external sagittal marrow, the efferent character of the internal sagittal marrow, subcortical fibers toward the motor area, and the absence of fibers to the frontal lobe

DISCUSSION

Dr L F BARKER, Baltimore, regarded definitely proving many of the po

ties as
re of

especial value. The subject is of great importance in diagnosis and the anatomy of these parts should be further elucidated.

Certain Features of the Nervous Breakdown.

DR JAMES J. PUTNAM, Boston, regards as the most striking example of this acute breakdown the so called traumatic neurosis, though strains during school and college life and intercurrent events during chronic illnesses are also effective in its production. The controlling influence in the causation of these states, and also the controlling means of treatment, is the mental state of the patient. The methods of treatment must be based largely on re-education of the patient, specially the increase of his available stock of mental energy. The objects to be aimed at are two. First, to make the person more efficient, second, to make him more philosophic and ethical. In general it may be said there is no single clue to all methods of treatment.

DISCUSSION

DR ADOLF MEYER, New York, believes there is a possibility of misconception if the physician is asked to teach philosophy and ethics. This is a most important point, however, and both these will find a foundation as has psychology. The ethics of habits and reaction types will become of prime significance.

DR CHARLES L. DANA, New York, regards a large number of these cases not a nervous breakdown, but a psychosis. Some patients get over the condition in a short time, but with many it lasts.

DR ABRAHAM JACOBI, New York, has in such cases almost always found changes in the heart, in some the presence of murmurs. Hence one must remember there is a physical change, as well as the psychic to be treated.

DR S. WEIR MITCHELL, Philadelphia, said these cases are sometimes emotional conditions, sometimes physical breakdown. It is often a complicated condition that works out in the sick room into its component parts. Cases that begin acutely are extremely rare.

DR PUTNAM said that we rarely see acute cases except those due to trauma. Here strong encouragement is often effective. The condition is not a pure psychosis, hence the visceral and other tissue changes must be observed and treated.

Clinical Study of Aphasia

DR CHARLES L. DANA, New York, studied some 30 cases of aphasia. Nearly all cases fall into one of four groups. First, pure motor aphasia, second inability to read, third, sensory aphasia of Wernicke, fourth, mixed cases, in which speech, reading, writing, comprehension, in fact, almost everything, is lost. Students learn to say where the lesion is when the symptoms of these groups are presented. Apraxia occurs only with bilateral lesions, as a rule.

DISCUSSION

DR WILLIAM THOMSON, New York, can work out 27 types of aphasia instead of 24, as mentioned by Dr Dana. He detailed three cases, all absolutely devoid of motor symptoms.

DRS STARR, PUTNAM, PRINCE and DANA all stated their conviction that the contention of Marie that the speech center is not in the convolution of Broca is not proven.

Inflammatory Masses in the Abdomen Simulating Malignant Growths.

DR E. G. JANEWAY, New York, described several cases in which firm masses in the abdomen, with or without exploratory operation, were pronounced inoperable tumors, but which later disappeared entirely. Some of these were in the iliac fossa, two in connection with gastric ulcer, and two in the region of the gall bladder. These cases teach the clinician not to be too hasty in giving a bad diagnosis and prognosis. He has no doubt that the so called removal of some tumors by the Roentgen ray and other methods has been due more to the "tincture of time" than to the agent employed. They also teach that operation does not always absolutely settle the diagnosis.

DISCUSSION

DR WILLIAM OSLER, Oxford, Eng., said that often physicians have been deceived by these cases. They may be grouped in three classes, as they pertain to the region of the gall bladder, the stomach or the appendix and cecum. His attention has lately been directed to a group of cases in which a mass is felt in the sigmoid region. This may be due to thickened glandular epiploica which will deceive the elect, or to perforation of a foreign body or pericolic inflammation. He agrees as to the fallibility of surgical operation, but always urges early interference. Some operations are disappointing, but many are satisfactory.

DR A. MCPHEDRAN, Montreal, spoke in this connection of tuberculous peritonitis. He believes that more cases of this disease recover without than with operation. He also mentioned a case of supposed malignant tumor of the pyloric end of the stomach for which gastroenterostomy was performed and which entirely disappeared.

Etiology of Acute Pancreatitis

DRS H. U. WILLIAMS and F. C. BUSCH, Buffalo, analyzed cases from the literature and reported experimental observations. In cases where gallstones are absent they suggest that the previous passage of gallstones may have dilated the ampulla of Vater and thus allowed intestinal contents to pass into the pancreas. Experiments on cadavers suggested the possibility of this occurring. In some animals they caused pancreatitis by injecting into the pancreas duodenal contents. They also pushed through the duct bodies similar to gallstones and then tried by pressure to force duodenal contents into the pancreas. In some instances they succeeded in thus causing pancreatic lesions. In consideration of physiologic facts it appears that autodigestion of the pancreas indicates the entrance into the organ of enterokinase, but the introduction of that substance into the pancreas did not produce pancreatitis.

DISCUSSION

DR. ELGENE L. OPIE, New York, said it is not improbable that the mechanism mentioned by the writers does occur and that pancreatitis is due to the entrance of duodenal contents. However, the cases in which he has seen large stones in the ampulla of Vater have been those of chronic rather than acute pancreatitis, it appearing that bacteria instead of duodenal contents entered. Bile and bile salts appear specially efficacious in producing pancreatitis.

The Calcium, Magnesium, Phosphorus and Nitrogen Balances in a Case of So called Phosphatic Diabetes

DRS L. F. BARKER and C. VOEGTLIN, Baltimore, reported this case, the patient being a woman of 39, who for years suffered from dry skin, cracking of the heels, nervousness and periodic losses in weight. The urine was constantly of high specific gravity and high acidity. She was put on Folin standard diet and the salts measured. The results showed an abnormal metabolism. The calcium was at first high, more than double the normal. The phosphates were increased, but became about normal on diet. The total acidity of the urine was striking, running at times to 1,500 cc. five times the normal, and averaging 700 cc. on Folin diet. The relation of this form of acidosis to other forms due to starvation, diabetes, acute infections etc., is interesting. There was no acetone or diacetic acid in the urine and the acidity was not due to lactic, hippuric or uric acids. The real cause is not known. Carbohydrate metabolism was normal in this patient, hence it appears different than diabetic acidosis. Whether this condition leads to the exhaustion of calcium and other salts is an interesting question.

DISCUSSION

DR WILLIAM OSLER said the chief point of interest in this case is that any one would have pronounced it a case of diabetes until the urine was examined, but repeated tests failed to show the least trace of sugar. When he saw the woman he regarded the case as one of prediabetes and expected each examination of the urine to show that sugar had appeared.

DR A E FAYLOR, San Francisco, said he tested on himself the effect of an ash free, alkali free diet and felt nothing but lassitude for six days, when itching of the skin and general irritability began. Sleep became impossible and diacetic acid appeared. This was regarded as a danger signal and ordinary diet was resumed with disappearance of symptoms in a few hours. Here the equilibrium was disrupted, though there was no particular withdrawal of calcium.

DR BARKER said that salts are just as important in diet as are fats and carbohydrates. There must be equilibrium or the muscles, including the heart, and nerves can not act properly. These results constitute an interesting outlook for the future in determining the origin of disease.

Relations Between Diabetes and Pregnancy

DR AUGUSTUS A ESHNER, Philadelphia, collated the literature on this subject, comprising 34 cases, and reported an unusual instance. A colored woman of 34, who had had sugar in the urine for three years, became pregnant. During pregnancy sugar disappeared, but again appeared shortly after the birth of a macerated fetus at term. He found no similar case in literature. Diabetes is uncommon during pregnancy, and this condition rarely occurs in diabetics. The complication of one with the other usually increases the gravity of both. Often the fetus dies *in utero*, or premature labor occurs. The mother sometimes dies of the disease shortly after labor.

DISCUSSION

DR JAMES TAYLOR, Philadelphia, now has under observation a diabetic woman who became pregnant while under treatment for the disease, the urine showing 2 to 5 per cent of sugar. The symptoms have been in no way aggravated and pregnancy is now near term.

Experimental Fibrinous Pleurisy

DR EUGENE L. OPTIE, New York, detailed experiments which show that the disappearance of fibrinous exudates in the pleura can be studied under conditions analogous to those which obtain in pleurisy and pneumonia in man. He injects turpentine into the pleural cavities of dogs, producing sero fibrinous pleurisy. Accumulation of fluid is at the maximum at the end of three days and fluid has entirely disappeared at the end of six days. Resolution of fibrin begins while fluid is present and is completed after the fluid has disappeared. In the first stage the fibrin digests itself in the presence of weak alkali, but later does so only in the presence of weak acid. It is possible that carbon dioxide, acting in the body as an acid, promotes resolution of the exudate by the enzyme. By aspiration of fluid and other means, as by repeated injections of turpentine, the characters of the exudate may be modified, even changed from sero fibrinous to purulent.

Certain Acoustic Limitations of the Stethoscope and Their Clinical Importance

DR LEWIS A. CONNOR, New York, studies confirm that certain sounds can be heard by the unaided ear and not by the stethoscope. In the heart this is specially true of certain murmurs of aortic insufficiency, whizzing in character. In the lung it is true of high pitched bronchial and also of amphoric breathing. Three points were offered in explanation of this fact. First, high pitched sounds are less readily propagated in closed tubes, especially elastic tubes. Second, when the ear is placed on the chest wall sound is transmitted by the bones of the skull as well as by the ear itself. Third, all chest sounds are composite and some bear certain relations to the tube of the stethoscope and are by it increased or diminished. The practical point is that students are wrongly taught to use only the stethoscope, they should be encouraged to use the ear.

DISCUSSION

DR S. SOLIS COHEN, Philadelphia, finds it difficult to make students trained only to the stethoscope hear the sounds he does. Another point is that the stethoscope changes many sounds. The sole advantage of that instrument is in localizing sounds previously discovered by the ear.

DR E. G. JANEWAY, New York, said that certain pneumonias do not give sounds with the stethoscope. He also encountered one instance of a cavity not possible of demonstration with that instrument, though its presence was conclusive.

DR ABRAHAM JACOBI, New York, mentioned the difference in area covered by the ear and the stethoscope as one source of difference in their findings.

(To be continued)

Marriages

SYLVIA F. HARRIS, M.D., and Samuel Hardy of Nevada, Cal., at Berkeley, Cal., May 9.

HENRY L. STEVENS, M.D., to Miss Kittie Kinnear, both of Laramie, Wyo., April 30.

ERA M. SCOFIELD, M.D., to Miss Bessie C. Brown, both of Jamestown, N. Y., April 30.

EDWIN B. DAUGHERTY, M.D., Eveleth, Minn., to Miss May Alness of St. Paul, May 1.

FRANCIS M. WALSH, M.D., to Miss Eleanor Gertrude Murphy, both of Philadelphia, April 27.

CHARLES EDWARD KLONTZ, M.D., to Miss Elizabeth Case, both of Cherry Valley, Ill., May 2.

JOHN R. OSBORN, M.D., Prospect, Ohio, to Miss Hazel Barber of Rushsylvania, Ohio, April 30.

JOHN T. HARBOTTLE, M.D., to Miss Margaret Louise Hayes, both of Columbus, Ohio, April 30.

WALTER W. SMITH, M.D., Reily, Ohio, to Miss Marguerite Kitchell of Kitchell, Ohio, April 30.

JOHN H. SEAMAN, M.D., New Haven, Mich., to Mrs. William P. Sprague, at New Haven, April 2.

E. E. BRUNNER, M.D., Carrollton, Mo., to Miss Mary D. Neal of Southport, Eng., at Centralia, Mo., April 29.

FERDINAND AUSTIN KITTINGER, M.D., Lockport, N. Y., to Miss Adelaide F. King of Buffalo, N. Y., April 30.

CHARLES A. D. CLARK, M.D., Harbor Springs, Mich., to Miss Matilde Beit of Sherman, Mich., at Cadillac, Mich., April 27.

Deaths

John Traston Main, M.D. Castleton (Vt.) Medical College, 1857, a member of the American Medical Association, some time a member of the House of Representatives and Senate of Maine for a long time a private pupil and assistant of Dr. Oliver Wendell Holmes, assistant surgeon of the Second Maine Volunteer Infantry in the Civil War, a member and president of the board of health of Jackson, Mich., and medical inspector of the City Hospital died at his home in Jackson, May 1, after a long illness, aged 75.

Carl L. Rominger, M.D. University of Tübingen, Germany, 1840, a member of the Washtenaw County (Mich.) Medical Society, the American Association for the Advancement of Science and the American Geographical Society, for many years state geologist of Michigan, and a recognized authority on his specialty died at his home in Ann Arbor, from senile debility, April 22, after an illness of four months, aged 86.

John Sweetland, M.D. Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons Kingston Ont. 1853, sheriff of Carleton County, Ont., formerly coroner for Lanark and Renfrew counties and surgeon of the County of Carleton General Hospital, president of the Medical Chirurgical Society, died at his home in Ottawa, Ont., May 5, from disease of the liver, after a long illness, aged 71.

Irvin B. Webber, M.D. Cincinnati College of Medicine and Surgery, 1870, a member of the Indiana State and Kosciusko County medical societies, president of the Northern Indiana Medical Association, United States pension examiner and health officer of Warsaw died on a street car while returning home from Winona Lake, May 1, aged 61.

William Harrison Jopes, M.D. Missouri Medical College, St. Louis, a member and president of the board of managers of State Hospital No. 3 Nevada, Mo. for about 14 years, died at his home in Greenfield Mo. April 12, from stricture of the colon after an illness of three months, aged 72.

James Dudley Peadleton, M.D. University of Virginia, Department of Medicine Charlottesville, 1860 for 30 years assistant clerk of the senate of died

suddenly at the home of his daughter in Bedford City, Va., April 10, from cerebral hemorrhage, aged 77

Marvin Stephen Butties, M.D. New York University Medical College, 1865, once vice president and president of the East River Medical Association, from 1864 to 1873 professor of obstetrics in the Medical Department of the University of the City of New York, from 1865 to 1872 surgeon of the Seventy-first Infantry, N. G. S. N. Y., founder of the Olivet Female Infirmary, and medical officer of the New York fire department, died at his home in New York City, May 9, aged 73

Arthur Bertin De Villeneuve, M.D. Medical Department of the Tulane University of Louisiana, New Orleans, 1872, well known as a physician, journalist, musician and linguist, died at his home in New Orleans, from heart disease, April 30, after an illness of six days

Charles Williams Ottley, M.D. Johns Hopkins Medical School, Baltimore, 1899, formerly of Atlanta, Ga., for several years professor of biology in Robert College, Constantinople, Turkey, died at Johns Hopkins Hospital, May 8, from postoperative pneumonia, aged 38

William H. Hotchkiss, M.D. Medical Institution of Yale College, New Haven, Conn., 1872, a specialist in diseases of the eye and ear, died at his home in New Haven, May 2, from cerebral hemorrhage, after an illness of a few hours, aged 60

Fulton Rogers, M.D. Medical Department of the Tulane University of Louisiana, New Orleans, 1867, a member of the American Medical Association, died recently at his home in Napoleonville, La., from chronic interstitial nephritis, aged 60

George H. Fossard, M.D. Albany (N. Y.) Medical College, assistant surgeon in the Army during the Civil War and chief surgeon of New York Volunteers, died at his home in Brooklyn, N. Y., May 10, aged 68

James W. Ferguson, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1876, of Haslett, Mich., died May 6, in a hospital in Toledo, Ohio, where he was under treatment for inflammatory rheumatism, aged 58

James O. H. Banks, M.D. Hahnemann Medical College and Hospital, Philadelphia 1873, died at his home in Pocopson Township, Pa., April 29, from cancer of the rectum, after an illness of two years, aged 78

William B. Tackett, M.D. University of Louisville (Ky.) Medical Department, 1849, one of the oldest practitioners of Johnson, I. T., died at his home in that place, May 2, from senile debility, aged 82

Lester F. Smith, M.D. Illinois Medical College, Chicago, 1906, died at the home of his father in Brazil, Ind., May 1, from uremia following an operation on the prostate gland two weeks before, aged 23

William Jackson Kendall, M.D. College of Physicians and Surgeons, Baltimore, 1884, died at his home in Paris, Va., February 20, from pneumonia, after an illness of five days, aged 45

Samuel G. Milner, M.D. Homeopathic College, University of Michigan, Ann Arbor, 1877, of Detroit, died at Grace Hospital, in that city, May 2, a few hours after a surgical operation, aged 61

Ira Lee Forsee, M.D. Chicago Homeopathic Medical College 1904, died at his home in Louisville, Ky., May 2, from pneumonia following typhoid fever, after an illness of two months, aged 25

James Warren Cameron, M.D. Hahnemann Medical College and Hospital, Chicago, 1878, died at his home in Salina, Kan., April 20, from appendicitis, after an illness of one week, aged 60

James H. Ferrell, M.D. Homeopathic Hospital College Cleveland, 1885, died at his home in Marion, Ohio, May 3, from uremia, after an illness of two weeks, aged 55

Frederick Volz, M.D. Jefferson Medical College, Philadelphia 1892, died suddenly at his home in Bloomington, Ill., March 27, from pulmonary hemorrhage, aged 42

Anabel Holmes, M.D. Woman's Medical College of Pennsylvania, Philadelphia 1892, formerly of Chicago, died April 22, at her home in Portland, Ore., aged 43

James A. Elder, M.D. St. Louis (Mo.) Medical College 1879, formerly of Saline County, Mo., died at his home in Potosi, Mo., April 14, from paralysis

Willard W. Wilcox, M.D. Dutton Medical College Chicago 1899 of Oklahoma City, Okla., was drowned while bathing at Tampico, Mex., recently, aged 60

Augustus H. Warren, M.D. New York University New York City, 1886, formerly of La Grange, Ill., was found dead in Quinc, Ill., April 16, aged 70

Miscellany

THE INTERNATIONAL MOTHER TONGUE

A Plea for the Use of Latin Derivatives to Facilitate the Reading of Articles by Foreigners.

E. OUSHING, CHICAGO

In no other science or profession is there such constant and widespread interchange of ideas as between members of the medical profession in all lands, all working to a common end.

Everything that tends to make international communication easier is a direct boon to science and to the profession. The present agitation in favor of Esperanto shows the craving and blind groping for an international tongue. Those who are promoting Esperanto and Volapük overlook the fact, however, that every one now has at his command at least 5,000 words which are practically the same in English, French and all the Latin tongues and are understood by scientific Germans and others. Every word derived from the Latin is understood at once by any one who has ever studied Latin or is familiar with French, Spanish, Italian or Portuguese, scientific Russian, scientific German, scientific Danish, Swedish, etc. Terms from the Greek are also alike in all languages.

THE JOURNAL has already drawn attention to this fact, and has shown that a sentence can be couched in good English terms which yet will be intelligible to persons of other nations, with, perhaps, the exception of the more common, shorter words, prepositions and conjunctions which can be looked up in the dictionary and easily learned. Writers would aid the progress of science if they would bear this fact in mind, and, at least in the titles of their articles, use such terms as are understood the world around.

If medical writers would take pains to couch the summaries at the end of their articles in this International English, as it might be called, the cause of science would be immeasurably promoted. There is no doubt that anything "the Americans" have to say is listened to abroad with interest and respect—when it is understood. If other nations followed this same plan of using words which are already in international use, the reading of their scientific articles would be much facilitated for us.

All scientific journals and works in Germany have long been published in our ordinary type, and it is used commonly everywhere now, except in far eastern Europe. Consequently, there is no difficulty from this source. A knowledge of the verb "to be" and of the articles "the" and "a" is not indispensable, as the sense is so easily made out without them. "Is" and "are" are omitted as superfluous in some languages, and we know that Latin has no article, having only eight parts of speech.

The summary at the end of Dr. Camp's article on "Paralysis Agitans" in THE JOURNAL for April 13, page 1239 is a model specimen of this International English. There is only one word "disease," which a foreigner would have to look up in the dictionary, besides an occasional preposition. The prepositions he would soon learn by heart if he could hope for frequent summaries in International English.

We quote the summary referred to in full, to show how beautifully the English language adapts itself to international use. The word "disease"—which is from a Gothic root and has no counterpart in other languages—might have been replaced by "malady" when the whole contents of the summary would have been clear to any scientific foreigner.

1 Paralysis agitans is not a neurosis nor is it senility.
2 The anatomic basis of the symptoms muscular rigidity and tremor and the symptoms depending on them lies in the affection of the muscles.

3 The disease itself is probably a general toxemia and there is suggestive evidence that it is due to alteration in the secretion of the parathyroid glands.

The conclusions of Camp's article in German, worded with a view to international comprehension, would read as follows:

1 Paralysis agitans ist nicht eine Neurose und ist nicht Senilität.
2 Die anatomische Basis für die Symptome Muskelrigidität und Tremor mit den davon abhängigen Symptomen liegt in der Muskelaffektion.

Die Paralysis agitans selbst ist wahrscheinlich eine generelle Toxemie die aus alterierter Sekretion der Parathyroiden hervorgeht.

In French the same conclusions would read

- 1 La paralysie agitante n'est pas une névrose et ce n'est pas la sénilité
- 2 La base anatomique des symptômes, rigidité musculaire et tremblement et les symptômes qui en dépendent, résident dans l'affection des muscles
- 3 La maladie propre est probablement une toxémie générale et les phénomènes observés plaident en faveur de l'assumption qu'elle est le résultat d'une altération dans la sécrétion des glandes parathyroïdiennes

Comparison with the original English will demonstrate that every writer in every language has it in his power to couch at least the titles and summaries of his articles in an international mother tongue which will be understood by scientists under every flag

The conclusions of Camp's article would not have been understood at all by the foreigner if they had been worded as follows. He would have had no idea that the writer was discussing paralysis agitans

- 1 Shaking palsy is not a nervous disease nor is it the decay of old age.
- 2 The anatomic groundwork of the perceptible change in function, stiffness of the muscles the shaking and the changes in function springing from them lies in a diseased condition of the muscles
- 3 The disease itself is probably due to the action of poisons in the blood, and there are grounds for supposing that it is the result of changes in the secretion of the parathyroid bodies

Couched in these terms the foreigner would view the summary "as through a glass, darkly," and pass over it without heed, skipping it as absolutely beyond his comprehension, even although he might be specially interested in Parkinson's disease.

In writing for international comprehension, it must be remembered that figures are the same in all languages and are recognized at once by readers of all nationalities. They frequently provide welcome stepping stones when an explorer is making his way with difficulty through the morass of an unfamiliar language, "2" is understood by every one, but "two" only by those familiar with English. Such local terms as "mumps," "bowels," "Gemickstarre," "kusma," "coqueluche," and the like should be replaced by more scientific terms before an address or article is sent anywhere for publication.

Scientific writers, especially medical writers, are so modest that they often fail to realize that their article—if known to some investigator abroad—may lay the foundation or supply the finishing stone for some important structure with which their name will be indissolubly connected, or, at least, it may save other investigators from going needlessly over the same ground again.

The heedless may ask with the Irishman "Why should we take so much trouble for posterity? What has posterity done for us?" but the thoughtful will realize that scientific works are a mine of information for workers of this and future generations in all lands, and that everything which tends to aid in the dissemination of scientific facts now or later, hastens the reaping of the harvest.

Patent and Other Proprietary Medicines Abroad

The jealous regard for individual rights in the United States and in England gives the probable reason for the reluctance with which these countries have interposed legal restrictions on the trade in "patent" and proprietary medicines. The result is that in these two countries the nostrum maker has had more chance to humbug the public and the profession than in any other country. However, there is an awakening in England as well as here. The *Lancet* in its issues for November 17 and 24 contains a review of the subject of "patent" and proprietary medicines by a barrister at law who takes up the matter from the lawyer's viewpoint. While we can not give space to the complete article which we would like to do, we think the following quotations and abstracts are worthy of reproduction.

"There are virtually no restrictions in Great Britain on the sale of proprietary secret medicines so long as these contain no scheduled poison and no considerable proportion of alcohol. By the use of the medicine stamp, absolute proprietary rights and absolute secrecy with regard to the composition of any medicine whatever may be indefinitely maintained." Medicines containing scheduled poisons must be sold at retail only

by a registered pharmaceutical chemist or chemist and druggist, and in the shop of a registered chemist or of a limited company and must be labeled poison. Scheduled poisons do not, however, include such articles as acetanilid, sulphonal and trional. Excise licenses are necessary for the sale of preparations containing much alcohol.

Patents are granted to medicinal preparations for the period of fourteen years on the theory that they are novel and useful. The patent authorities are bound to search their records to determine the novelty of the new process, but have no authority to refuse the patent on the ground of novelty, but such a patent may be declared invalid if protest is made. According to high authority, a chemical substance is never the subject of patent. It is only the process of manufacture that can properly be patented. A trademark gives usually better protection to the proprietor of a medicine than a patent. To secure the protection of a trademark it is not necessary to show that the remedy is new or useful, but the name must be non-descriptive and can be registered at any time and applied to the remedy whenever it becomes convenient. It protects the property in the name, not only for fourteen years, but forever. The manufacturer attempts to secure a word which approaches, as near as may be safe to the border line between descriptiveness and non-descriptiveness. The *Lancet* aptly illustrates this by the case of "tabloid." "The registration of the hybrid word, 'tabloid'—derived from a thoroughly familiar Latin root and an equally well known Greek suffix—was a masterpiece of foresight and sagacity. The word so aptly describes the article to which it is applied that it naturally springs to the lips of the average person who wishes to buy compressed tablets, yet the word has been held by the Court of Appeal to be a valid mark and is private property for all time. The result is that there is a permanent quasi-monopoly in an article of commerce which was at one time the common property of all traders."

The shrewdness of manufacturers has led them to perpetuate the rights obtained by patent after the expiration of the patent by advertising the article under the trademarked name and thus continuing indefinitely the protection of the trademark to the article which has become known under that name. Decisions of the English courts have, however, made this protection invalid if anyone sees fit to contest it. "Where an article has been introduced as new and has first been manufactured under a patent, the name by which it is known becomes common property as soon as the expiration of the patent rights puts an end to the monopoly in the manufacture and sale of the article" (Kerly on Trademark-). Unfortunately, it is not worth while for any one firm to incur the expense of moving the court in order that the whole community may share in the benefits obtained. So as often as not, the monopoly persists and the public, of course, has to pay

EXCLUSIVE RIGHTS TO PUBLIC PROPERTY

A good example of the abuses to which the patent and trademark laws are subject is shown by the following quotation from the *Lancet* article.

"There are at the present moment many firms of manufacturers who devote much thought to the perfection of devices whereby they may secure exclusive rights in this or that medicinal substance which is now public property. In some instances they boldly apply for a patent for some already known chemical substance or process, trusting that the insufficiency of present requirements of the law with regard to novelty in an application for a patent or the complexity of their specification or the addition perhaps of some illusory 'improvement' and the inactivity of other traders will enable them to achieve their object. A good example of this is to be seen in the acetyl salicylic acid [Aspirin] case recently before the courts. In that case it was shown that a patent had been obtained and for many years enjoyed in respect to a chemical compound, the process for manufacturing which was perfectly well known before the patent was issued. The judge in declaring the patent invalid remarked that, by error accident or design, the specification had been so framed as to secure, as far as possible, the exclusive right to the compound."

"But it is rarely that this method of securing proprietary rights in medicinal substances is attempted. The easier and more usual method is to apply to the coveted remedy a trade mark consisting of some 'invented' word. This may be chosen especially to suit the substance or it may be a word which the manufacturer has had 'in stock' while he waits for some thing to turn up, to which the mark may suitably be applied. For example, since the acetyl salicylic acid patent was declared invalid rival firms have endeavored to 'collar' the trade in the compound by applying to it fancy trademarks and attempting to persuade medical practitioners to use these only when prescribing acetyl salicylic acid. Can it seriously be contended that there is such a difference between the brands of acetyl salicylic acid sold by A under the name of 'aspirin,' or by B under the name of 'saletin,' or by C under the name of 'salacetin,' or by D under the name of 'acetysal,' or by E under the name of 'salax,' and the compound sold under its proper chemical name, as to make it desirable in the interests of the public health that the state should protect five separate proprietary interests in what is to all intents the same article, and that a well known and useful piece of public property? And can it be regarded as desirable that the real nature of the compound should be masked by the use of all these fancy words? To give other examples, different brands of hexamethylene tetramine have the following fancy names: Urotropine, amino form, formin, cystamine, uritone and naphthamin, while adrenalin competes with suprarenalin, epinephrin, adnephrein, adrin, suprarenin, haemostasin, renastypin and paranephrein. All these, or nearly all, are registered trademarks."

AS OTHERS SEE US

In the second article the *Lancet*, November 24, the United States is designated as the "home of all that is worst in the proprietary medicine trade." Preparations strong in alcohol and morphin "flourish exceedingly." The attempts at legislation in various states are noted and their failure attributed to "strenuous opposition from the newspaper press, nearly the whole of which is afraid to offend the advertising nostrum manufacturers." "But in some respects the governments have powers which are not possessed in Great Britain. For instance when 'Liquozone' was publicly exposed in 1905, although no attempt was made by any government department in Great Britain to take action in the matter, the San Francisco board of health, exercising power vested in it, promptly forbade the sale or distribution of 'Liquozone' on any terms whatever within the area of the board's jurisdiction."

CUBA.

In Cuba a law requiring the publication of the ingredients of proprietary medicines on the labels was modified through the influence of the nostrum proprietors so that the disclosure need only be made to a government official pledged to secrecy. In Porto Rico the law requires that all the formulas of all proprietary medicines shall be filed with the government before the medicines can be sold. The law had an immediate effect on nostrums imported from the United States and the Porto Rico druggists ceased to sell many American proprietary medicines in which they had formerly dealt.

AUSTRIA

The laws of Austria are especially worthy of study. The qualified pharmacist is the only person who may compound or sell any preparation containing poison, and in all such cases a physician's prescription is necessary. Proprietary medicines can not be placed on the market without permission of the board of health which must first have been informed of the exact composition of the article, supplied with samples, and satisfied that the compound is in some way novel or useful or that it is presented in an improved form. No recommendation of any proprietary medicine as a cure for any disease is allowed, and all advertisements in the press and elsewhere are under the direct and strict supervision of the police. The price of proprietary medicines is fixed by the board of health, and foreign proprietary medicines are not allowed to enter the country unless under certain exceptional conditions. The law is said to work well.

FRANCE.

In France only qualified pharmacists may make and sell proprietary medicines, the formula must have been published (a) in the "Codex" or (b) by the government, or (c) in an issue of the *Bulletin de l'Académie de Médecine*, the publication of advertisements for secret medicines is contrary to law. The law is loosely enforced.

GERMANY

Germany excludes foreign proprietary medicines by a heavy import duty and regulates the traffic in home remedies by forbidding advertisements of certain remedies, requiring that the bottles shall not bear labels or be wrapped in circulars containing recommendations, certificates, etc. Some potent medicines may be sold only on a medical man's prescription. The composition of all scheduled remedies must be known to the druggist who sells them. Analyses of new medicaments and secret remedies are being made at the Berlin Pharmaceutical Institute and published in the *Apotheker Zeitung*. The regulations are not the same in all parts of the empire, but the general result is greatly to discourage the sale of secret remedies. A well known English proprietary medicine was voluntarily withdrawn from the German market by the proprietors, who objected to disclosing the formula of their preparation and did not think that much business could be done if its sale were subjected to the restrictions on secret medicines. The advertising managers of two Hamburg journals were each fined \$12 or five days' imprisonment for publishing advertisements of Allcock's plasters, the composition of which was not declared.

AUSTRALASIA

Australia and New Zealand appear to be especial sufferers from the proprietary medicine evil and the trade has reached enormous proportions there. A writer in *The World's Work* is quoted as stating that these countries imported in 1905 proprietary medicines of the invoice value of nearly \$1,500,000, many of them being of a flagrantly noxious character and advertised by grossly fraudulent means. Laws have been passed bringing medicines containing scheduled poisons under the regulations for the sale of poisons, and regulations have been established by the board of health of Victoria limiting the amount of alcohol in non official remedies of which the average dose is more than one teaspoonful for adults to 10 per cent, also requiring the publication of the presence of a long list of narcotics. The federal government is empowered to forbid the importation of proprietary medicines containing narcotics, etc., without a declaration of the contents on the label and may require the disclosure of trade secrets and may confiscate unapproved articles, the postmaster general may refuse to transmit letters sent in connection with a fraudulent business.

In New Zealand an attempt was made nearly three years ago to require certain nostrums to the number of 160 to bear on their labels a full disclosure of their constituents, with the quantity of each. The opposition of the proprietary men was so powerful through their influence with the business men and the newspapers that the regulation was toned down until it was required that the disclosure need be made only confidentially to the minister of public health, and only when such disclosure should be specially demanded. Thus whittled down the regulations clearly can not do much to protect the public.

Sanitary Conditions at Mauritius—Consul Bothin, in his report, gives the following information regarding the sanitary condition of this British island in the Indian Ocean. The island has an area of 715 square miles, including reefs, bars, etc. The population numbers almost 400,000 people, who live on an area of half that of the entire island. The remainder of the island consists of mountains, forests, and military reservations, where dwellings are forbidden, though little of such idle land is fit for human habitation. The total population consists approximately of 260,000 Indians, 5,000 Chinese, 80,000 creoles (negroes and mixed), and 50,000 whites. The drainage is naturally very good, and the natural condition has been greatly improved by the substantial manner of building the roads and the permanent drainage canals on each side of the roads. There are few swampy lands and no stagnant

water. Water for drinking and culinary purposes is derived mostly from Mare aux Vaeas, a fresh water lake that occupies one of the large ancient craters near the center of the island and furnishes from some hidden source an inexhaustible supply of very pure water, which is piped to all the towns and villages. Owing to the porous nature of the thin soil and of the lava rocks beneath it, the rain water carries downward much surface filth, contaminating well water and causing much of the fever prevailing among the Indian coolies and lower class of creoles. Malarial diseases are generally present along the coast. The constant prevalence of malarial disorders and fever forced almost the entire white population, years ago, to abandon the port towns. Except during about ninety days in June, July and August, annually, very few white people are to be seen in Port Louis after 5:30 p. m. During those ninety days a moiety of the whites venture to sleep near their places of business, but even then the risk of getting the fever is very great. Bubonic plague is another constant menace to the colored populations of the coast towns. Plague made its first appearance on this island about eight years ago, and all efforts to stamp it out and prevent its recurrence have failed. Beriberi appeared among the convicts at Beau Bassin prison about March 1, 1907, and created great alarm throughout the island, but the health officials soon had the disease under control. They assumed that the cases of beriberi were caused by the daily ration of Saigon rice, which only recently the authorities had been furnishing to the prisoners in lieu of Indian rice as formerly. Wholesome wheat bread was substituted and the use of Saigon rice strictly forbidden at the prison. The result was a disappearance of the malady.

Etiology of Beriberi.—The study of beriberi has been assiduous and has attracted the attention of a number of European and Japanese pathologists. So far no satisfactory explanation of the etiology of the disease has been arrived at, although the recent researches point in the direction of an infection. The investigations of Wright led him to believe that the symptoms are due to an intoxication from the products of the growth of a bacillus which makes its domicile in the upper part of the duodenum. The difficulty of demonstrating the pathogenic character of an organism found in the gastrointestinal canal has, however, prevented his theory from gaining ground. C. W. Daniels ("Studies from Institute for Medical Research, Federated Malay States," vol. 4, part 1), reports a large number of observations on this disease made in the Federated Malay States, which give a basis for certain conclusions, although they do not settle the question of the etiology of the disease. The occurrence of the disease in prisons gives a good opportunity for testing certain theories of the disease, especially those which attribute it to the effect of certain articles of diet and to the location or character of the dwelling. As the prison fare is practically identical in the various prisons, it is possible to eliminate its influence in comparing the statistics of epidemics in different prisons. The author reaches the following conclusions:

1. Beriberi is an infectious disease. As a rule a short period of incubation and a period of exposure of less than three months is requisite for full development of the disease where the endemic index is high.

2. There is no definite proof that intermediate host is required but the balance of evidence is against its being conveyed by earth, air, water or food or contamination with sewage or other fecal matter.

3. There is some evidence that for a short period only after the occupation of small spaces, beds, bedrooms etc. the 'poison' or carrier of infection may remain.

4. Food as regards quantity and quality, its nature or relative proportions may have an effect on the susceptibility of the patients although the proofs are not conclusive but is not the causative agent.

5. If an intermediate host for the unknown parasite is required, it must be either a cimex or a pediculus. Pediculi as carriers would better explain the incidence of the disease than any other blood sucker.

6. A closer inquiry into the earlier stages of the disease is required. Where opportunities for such an inquiry occur renewed attention should be bestowed on the blood and tissues with a view to determining the presence or absence of any protozoan.

7. Prophylaxis. In view of the failures of various attempts at disinfection of buildings and places and of various modifications of diet to have a marked effect more attention should be paid to limiting the chances of personal infection and particular attention should be paid to the personal cleanliness, freedom from vermin and isolation of early or trivial cases of the disease.

Pernicious Anemia Cured with Intravenous Injection of Corrosive Sublimate.—A young man was suddenly attacked with

high fever of an intermittent type, followed by sweats, and refractory to quinin and change of air. After the febrile period and an afebrile interval of nine days, remittent fever was observed, with vomiting, diarrhea and enlargement of the spleen, while the blood contained only 1,202,000 reds and 5400 whites, with 25 per cent hemoglobin. A week later the general condition was progressively worse and the blood picture was 645,000 reds, 4300 whites and hemoglobin 20 per cent, with numerous megaloblasts. Baccelli made an intra venous injection of 1 cg (1/6 grain) of corrosive sublimate, according to his well known technic, giving six injections in the course of 8 days. Within 6 days the blood picture had improved to 1,450,000 reds, 8800 whites and hemoglobin 29, three days later the reds numbered 2,208,000, the whites 6,500 and the hemoglobin had reached 35 per cent, while within three weeks of the last injection the blood findings were practically normal. Reds 3,500,000, whites 4,500, and hemoglobin percentage 70. Baccelli ascribes the fulminating progressive pernicious anemia to invasion of the system by some unknown germ which is destroyed by intravenous injection of sublimate. The patient has since had an attack of acute gastrointestinal disturbance with malarial symptoms, after errors in diet, and the parasites of quartan fever were found in the blood, but he recovered under a few doses of quinin, and the blood picture at no time showed any tendency to the pernicious anemia type. He has since been in good health. The case is reported in the *Polieclinico*, xiv, page 149, 1907, the communication ending with the remark: "We hope that physicians everywhere will give this method of treatment a faithful trial, for the benefit of humanity."

Recent German Legal Decisions in Regard to Medical Fees.—

A physician rendered an account in January of the fees due him from a certain patient, and when the account had not been paid in March, he brought suit for the amount. The judge affirmed that the defendant should have paid for the medical services at the time they were rendered. At the very latest he should have paid the bill at once on its presentation. In another suit a man was sent by his family physician to a specialist for a middle ear affection. The patient refused to pay the specialist any more than the regular fees he would have paid the family physician. The judge decided in favor of the plaintiff, affirming that a specialist is not justified in charging more than the regular fee without further notice. In another case the judge decided that the patient must bear the expenses of a consultation of physicians whether he had agreed to the consultation or not. If he wishes to protect himself against such expense he must inform the consulting physicians on their arrival that he does not want their aid. In another case a father had paid the physician's account for treatment of an aural affection in a child. The child returned to the physician again and was given another treatment for which a charge of about 75 cents was made. This the father refused to pay, as the child had returned without his knowledge or consent, but he was ordered by the judge to pay it.—From the *Zeitschr. f. ärztl. Fortbildung*, iv, 95, 1907.

Anesthesia of the Teeth from Cocain Tampon in Nose.—Esent has recently announced, and his statements are confirmed by Lederer, that a tampon moistened with cocain and inserted in the nose will induce anesthesia of the gums and teeth below the nasal fossa. The anesthesia does not develop until from 15 to 20 minutes after the tampon dipped in 5 or 10 per cent solution of cocain has been introduced into the nose. The anesthesia is most intense about the thirtieth minute, the tampon is then removed, and the anesthesia persists for 15 minutes longer, and then gradually subsides. In examination of 500 patients the anesthesia was found crossed in 8 cases, and in 37 the gum and teeth on the opposite side were also partially anesthetized. In Lederer's experience the anesthesia amply sufficed for operations on the teeth, even extraction of carious roots, and in a communication to the *Prag. med. Wochenschr.*, xxxii, 90, 1907, he discusses the anatomic basis for the phenomenon.

Ether to Check Suppuration.—Souligoux and Tillaux have reported unusually fine results from the use of ether in aborting suppurations. They scrub the skin with a freshly boiled

nail brush until the epidermis is removed, and then dress the part with several compresses dipped in ether, covered with oiled silk. Every hour a corner of the dressing is raised and more ether poured in to keep the compresses moist. This is kept up for several days and the suppuration retrogresses to complete absorption in a few days, without the necessity for an incision. An article in the *Tribune Med.*, xl, 217, 1907, describes some of their experiences. The favorable effect of the ether is ascribed to its penetration into the skin where it acts as a microbicide while stimulating phagocytosis.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and methods of treatment for the diseases seen especially in every-day practice. Contributions will be welcomed from our readers.]

THE METRIC SYSTEM AND HOW TO USE IT

W A Jolley, M.D.
BOULDER, COLO.

(Concluded from page 1631)

1 *Liquid Measurements*—Table 1 is intended to facilitate the acquirement of the metric system for practical prescribing, but it is not accurate enough for scientific work.

TABLE 1

15 minims	1 cubic centimeter
1 dram	4 cubic centimeters
1 teaspoonful	5 cubic centimeters
1 ounce	30 cubic centimeters
1 pint	500 cubic centimeters
1 quart	1 000 cubic centimeters

Prescriptions should be planned so that numbers to which we are accustomed in our monetary system may be used—that is, decimal fractions and the short cuts used in financial calculations.

The majority of acute conditions for which physicians are called to prescribe subside in two or three days and do not require more than about twenty doses of any remedy, and when it is remembered that a teaspoon holds about 5 c.c. it will be seen that 100 c.c. is all that need be prescribed. If the dose of the drug is less than 5 c.c. multiply the selected amount by twenty (20) and add some vehicle to bring the total amount to 100 c.c.

This is a convenient amount to prescribe when the medicine is to be given three times a day for a week. For one month 500 c.c. is approximately the quantity to prescribe if the medicine is to be taken at meal times as is usual in continued treatment.

When preparing antiseptic solutions 1,000 c.c. or 1 liter is convenient to use.

The following prescriptions will explain this more fully. Aconite is generally used in most fever mixtures, taken 0.5 c.c. at a dose. *Liquor potassii citratis* may be used as a vehicle. It requires practically no mental effort to write:

R Tincture aconiti (5x20) 10j
Liquor potassii citratis q s ad 100j
M Sig A teaspoonful every 4 hours

The following prescription containing *nux vomica* may be used when a tonic is to be given, for a month:

R Tincture nux vomice (5x100) 50j
Tincture gentiane comp q s ad 500j
Sig A teaspoonful before meals

The metric system has no equal when preparing solutions of a definite percentage. For example if there were no bichloride of mercury tablets it would take the ordinary man several minutes to decide on the proper amount to be used in a 2 to 1,000 solution but a prescription is easily written in the metric system:

R Hydrargyri chloridi corrosivi 2j
Aque q s ad 1 000j
Sig Poison Use for wash

2 *Weights*—It is more difficult to handle weights, for the quantities are so small and the specific gravity varies so greatly that one can not compare the different amounts as with liquids.

The term "one grain" conveys to the mind an idea of a definite quantity that has been used as a standard from habit, not for convenience. In the case of alkaloids the grain is divided very minutely and the term is dropped altogether if the amount is a dram or more.

The metric system offers a number which does not have these objections. I will take 0.05 gram, or 50 mg., as a basis for smaller calculations, because it is approximately a grain and can be used even if large quantities are to be weighed.

This has the same advantages that 5 c.c. has in the liquid measurements, but to secure the advantages of the decimal system the prescription should be written for 10, 20 or 50 doses if powders, pills, capsules, tablets, suppositories, or any solids are to be given. For example:

R Pulveris ipecacuanhe et opii (5x10) 5j
M Ft. pulveres No x

A great obstacle lies in the fact that tablets are not made in the metric system, so that physicians who dispense their own medicines think that they can use only the apothecaries' weights, but this is a mistaken idea. Tablets can be selected, the dosage of which can be stated approximately in the metric system, and so label them until the tablets are made in the metric weights, as they will be eventually. Table 2 gives an idea of the approximate equivalents, not accurate enough for scientific work, but close enough for practical dispensing.

TABLE 2

1/500 grain	=	0.00125
1/250 grain	=	0.0025
1/120 grain	=	0.005
1/60 grain	=	0.01 or 1 milligram
1/30 grain	=	0.02 or 2 milligrams
1/10 grain	=	0.05 or 5 milligrams
1/6 grain	=	0.1 or 10 milligrams
1/3 grain	=	0.2 or 20 milligrams
1/2 grain	=	0.3 or 30 milligrams
1 grain	=	0.5 or 50 milligrams
2 grains	=	1.25 or 125 milligrams
5 grains	=	3
15 grains	=	1 gram
1 dram	=	4 grams
1 ounce	=	30 grams

As a practical illustration I select a few of the above equivalents which can be used when ordering tablets:

Aconitin	1/500 grain can be labeled	0.00125
Strychnin sulphate	1/60 grain can be labeled	0.01
Strychnin sulphate	1/30 grain can be labeled	0.02
Calomel	1/6 grain can be labeled	0.1
Calomel	1 grain can be labeled	0.5

That sacrifices extreme accuracy for mathematical convenience as is the practice in writing prescriptions in the apothecaries' system.

It is easy to use the metric weights in ointments and suppositories. For example:

R Ichthyol 2j
Olei citronellae 50j
Adipis lane hydrosl
M et ft unguentum
R Pulveris opii 2j
Olei theobromatis 20j
M et ft suppositoria No xx

3 *Solids and Liquids*—Manufacturers and wholesale druggists use the avoirdupois ounce (437.5 grains) when selling drugs. A druggist may take an unbroken package without remembering this fact and fill a prescription with it, in which case the patient will receive less than intended. This can not occur in the metric system. The following prescription illustrates the ease with which solids can be accurately combined with liquids:

R Potassii iodidi (2x100) 25j
Syrupi sarsaparillae comp q s 500j
Sig One teaspoonful three times daily

The accuracy of the metric system is especially evident in handling alkaloids when percentage solutions are to be made, as is often the case with cocaine. For example:

R Cocaine hydrochloridi 14
Aque destillate q s ad 10j
M Sig Four per cent solution of cocaine

4 *Practice*—Having thus obtained a theoretical knowledge of the principles involved, a practical knowledge should be acquired by actual work with graduates, bottles, and scales, using common drugs until one is familiar with the different terms and the quantities they represent. The next step can be

patient at his own home. Such treatment must always be under the supervision of the physician. Among poor patients he advises the formation of a tuberculosis class, to which patients come once a week for directions. He maintains that the patient should go out of doors in rainy and snowy weather at all times of the year, properly protected from wet and wind. His clothing should be of the lightest weight and the smallest number of garments of any material that will keep him comfortable. Clapp believes that a morning temperature of 99 F indicates no exercise for the day, while over 101.5 calls for rest in bed for part of the day.

13 Rare Forms of Chorioiditis.—Bull calls attention to the chorioiditis that arises in the course of severe malarial infection and in intestinal intoxication. It is caused by microorganisms conveyed to the eye by the blood current, where they are arrested, and adhere to the walls of the chorioid vessels. Malarial chorioiditis is rare and found only in the severe southern forms of the disease. The entire uveal tract may be involved, including the chorioid, iris and ciliary bodies. The attacks are periodic, relapses are frequent, and the course is tedious. Treatment consists in the administration of quinin, iron and arsenic, with attention to the diet and general hygiene. Chorioiditis from intoxication of gastrointestinal origin is a still rarer condition. In these chorioid infections there are the usual symptoms. The physical findings are yellowish patches on the retina, similar to those seen in malaria, and a marked skin eruption of a pemphigoid type.

15 Pus Tubes in the Male.—Belfield says that pus infection in the seminal tube of the male is quite as frequent as in the Fallopian tube in the female. It is infrequently recognized, since the symptoms are common to other urinary conditions. Gonococci, pyogenic bacteria and tubercle bacilli are some of the causes of infection. The author suggests simple incision with a cautery knife from the rectum to relieve pus tubes. He also suggests that the vas deferens may be opened, the cut edges stitched to the skin and a solution injected through a curved hypodermic needle. Injections are made daily until the infection is over, when the fistula can be closed.

18 Sahli's Desmoid Reaction.—Carey verifies Sahli's results in determining the sufficiency of gastric digestion by means of the desmoid capsule. In the 25 cases on which he bases his results, it was found that, with but one exception, there was no discrepancy between the desmoid reaction and the analysis of the test breakfast. He believes that this reaction is of value in determining the digestive sufficiency of the gastric juice and its ability to digest the meal with which the capsule is given. In other words, it is a test for both free hydrochloric acid and pepsin, and a positive reaction indicates that both constituents are present in sufficient quantities to digest the full meal. As a means of differentiating between various functional disorders it is of little or no value. Neither does it give any clue as to stasis or loss of motility. Carey believes, therefore, that while it can not take the place of the stomach tube and test breakfast, it can be used as a valuable control. It permits of differentiating the mild from the severe cases of gastric insufficiency.

19 Roentgen Diagnosis of Urinary Calculus.—Brown emphasizes the value of what he terms the ante operative preparation of the patient when examination for urinary calculus is to be made by means of the Roentgen ray. He advocates local compression of the area to be examined and a previous emptying of the stomach and bowel, so as temporarily to force away the intestinal content from the renal, ureteral or vesical region. Arrangements for such an examination should be made at least 24 hours ahead. He recommends the use of castor oil as a preliminary purgative and the additional use of a soap sud and glycerin enema shortly before the sitting

- 36 Significance of Indican in the Urine or Those Afflicted with Certain Diseases of the Skin. M. F. Engman. St. Louis.

33 Diet as a Cause of Skin Diseases.—Stelwagon says that while certain foods are toxic to some individuals, it must be remembered that skin eruptions may be the result of over eating, or that even underfeeding, may be the result of toxic and putrefactive changes which the food has undergone before or immediately after consumption, and, further, the possibility of chemical preservatives and not the food itself should be borne in mind.

34 Diet in Treatment of Skin Diseases.—Fox believes that many persons affected with diseases of the skin are in the habit of eating too much, especially of nitrogenous foods. He says that, when prescribing a diet, it is far better to allow a few nutritious and easily digested articles for a time than to make out an expurgated diet list. The effect of the diet on the disease must be studied carefully in order that the patient may eat only that which he can digest and which does the most good. The food should also be prepared properly and the patient should eat regularly without haste and not while under the stress of excitement and worry.

35 Dermatitis Exfoliativa.—Foster reports 12 cases of this affection, four of which occurred shortly after birth. The treatment which Foster has found most satisfactory consists of prolonged permanent warm baths. After coming out of the bath the patient is enveloped in flannel, soaked with either cod liver oil or olive oil. Foster suggests administering carbolic acid internally in one half grain doses, watching the kidneys carefully.

- 39 *Management of Gastric Ulcer. J. W. Bell. Minneapolis.
- 40 *Therapeutic Abortions. C. Johnson. William.

37 Dangers in Impure Foods.—The dangers and the nature of impure foods are set forth fully by Vaughan, in fact, he covers almost the entire realm of food adulterations as well as food preservatives. He lays down the following requirements as being, in his opinion, the essentials of a substance before its employment as a food preservative should receive legal sanction. 1 It must be a real preservative, keeping the food in a wholesome condition and not merely retaining the appearance of freshness while bacterial changes continue. 2 In the largest quantities used, it must not materially impair any of the digestive processes. 3 It must not be a self poison in any amount or if such, it must be added to foods only by persons qualified by special training and officially authorized, and food containing these substances must be labeled plainly and the kind and amount of the preservative used must be made known, not only to the buyer but to each consumer.

38 Sanatorium Treatment of Tuberculosis.—Klebs' views on this subject are so well known that it is not necessary to repeat them

39 Management of Gastric Ulcer.—The treatment described by Bell agrees with that generally employed in cases of acute and chronic gastric ulcer

40 Therapeutic Abortion.—Johnson is of the opinion that therapeutic abortion is generally advised too reluctantly. In stead of being a remedy of last resort, it should be advised early, whenever the condition of the mother is such that there is no reasonable probability that she can carry the fetus to the age of viability without serious danger to life and health

- 46 Case of Submucous Nasal Septum Resection R A Campbell Minneapolis

41 Chronic Otorrhea.—Spratt points out the dangers that may result from a neglect to treat a chronic discharge from the ear. He advises early incision of the tympanic membrane as a prophylactic measure, and cleanliness, free drainage and operation, if necessary, as curative measures

42 Mercury in Syphilis.—The use of mercury in the treatment of syphilis is discussed in general by Crume. With regard to hypodermic injections, the only objection he has to them is that they are painful, nor are they indicated, he says, when the patient is debilitated by other diseases or when he is very obese. Certain it is, Crume declares, that it makes relapses not only less severe and frequent, but obstinate, virulent and malignant types become a rarity

44 Hydatid Moles.—Batcheller reports one case and discusses the clinical history of the condition. His patient went to term, delivery was uneventful, but the postpartum flow lasted for about two weeks

45 Refractive Error as Cause of Headache.—Sherman reports three cases to illustrate how both refractive error and other derangements must be corrected in order to secure relief from severe headaches

- 59 Pneumonia E T Bruce Louisville

48 Treatment of Gonorrhea.—The point especially emphasized by Heflin is that whether the case be treated by irrigations, injections, internal administration, or along other lines, the treatment should be continued until the patient is well—not until the discharge ceases, but until the urine is free from shreds and the microscope fails to reveal the presence of the diplococcus of Neisser

54 Treatment of Placenta Prævia.—Beard reports two cases of placenta prævia, in one of which there was a twin pregnancy. In the latter there was a double placenta prævia marginalis. In both cases a successful delivery was effected.

55 Unusual Obstetric Case.—The case reported by Beauclump was one of left acromio iliac presentation. Embryotomy was done after all other attempts at delivery had failed. The head was hydrocephalic, the occipito mental diameter was 12 inches

56 Cancer of Intestine.—Barrow reports three cases of cancer of the intestine, in which operation was done. One patient

died 18 months after the operation from recurrence of the growth, causing obstruction. The remaining two patients are well, one two years, and the other four years after operation. In both of these cases the tumor involved the cecum, necessitating the resection of a portion of the cecum and the ileum

62 Preserving Outlines of Visceral Lesion.—In order to increase the accuracy of his examination, Kelly makes a pictorial record on a transparent stiff tissue, such as nainsook, or suisse material, laid over the abdomen, on which the surface markings seen beneath are easily transcribed. New records are made each time the patient returns for examination, thus permitting of comparison. An aniline or crayon pencil may be used

64 Acute Pancreatitis.—Egdahl concludes his review of 105 cases of acute pancreatitis as follows: 1 Gallstones are probably the most common single cause of pancreatitis. Judging from this series, about 42 per cent of the cases of acute pancreatitis are associated with gallstones. 2 Gastrointestinal disorders are the next most common cause of acute pancreatitis. In this series of cases about 30 per cent belong to this group. Seventeen out of 32 of this group gave a history of alcoholism. It is probable that retrojection of bile may be caused by intestinal disorders closing the papilla of Vater. 3 Acute pancreatitis may be caused by many other conditions, such as typhoid, tuberculosis, mumps, trauma, syphilis, emboli, appendicitis, malaria and gastric ulcer. 4 The organism most commonly present is *B. coli communis*, next comes the streptococcus and the staphylococci. 5 Typhoid is the most common of the acute febrile diseases present according to the previous histories of these acute cases of pancreatitis. In the present series three were associated directly with typhoid fever alone, and four had suffered from typhoid some time before the onset of the pancreatitis, and had apparently recovered, another had had typhoid and erysipelas. But two out of these cases were associated with gallstones

conclusions from this research and other experiences are that life insurance companies are not justified in excluding from insurance all persons with chronic ear affections, as they do in Germany. If the ear affection is shown by its clinical course to be a benign one, the life expectancy is scarcely affected by it, and candidates should be accepted, with an extra premium. The decision as to the benign character of the affection can be made only by a specialist.

78 Exercise During the Intervals Between Classes.—Mushat urges brief and frequent gymnastic exercises, between classes, not attempting many movements, but doing each exercise very carefully and with precision. He states that the medical school inspectors have reported that about half of all the school children suffer from curvature of the spine, not including the children who are merely round shouldered.

80—This paper is practically the same as that which appeared in *THE JOURNAL*, May 11, 1907, page 1586, by Hoffa and Wollenberg.

81 Tetanus.—Tilmann relates a case in which gangrene developed three days after a child had been kicked in the arm by a horse. The arm was amputated at once, but two days later tetanus developed and the child succumbed. He calls attention to the case to show that amputation, removing the focus, is not inevitably of benefit in case of tetanus. In this case the focus had been removed two days before the first symptoms of tetanus. The operation was done in a well equipped operating room and infection with tetanus during the amputation is out of the question. In another case of tetanus described the knee had been run over and a large skin flap torn off. Symptoms of tetanus developed on the tenth day and 10 cc of tetanus antitoxin were injected into the spinal canal and the same amount into the right sciatic nerve, with morphin and chloral every hour. The next day 12 cc. of antitoxin were injected into the sciatic nerve on the left side, and the next day 20 cc into the right side. The patient soon recovered. Every suspicious wound at Tilmann's clinic is examined for tetanus bacilli, if found, antitoxin is injected at once.

82 Modification of the Bassini Technic.—The details of the technic are shown in several illustrations, as it has been applied in 89 cases in Papaiannou's service and in 21 elsewhere. Primary healing without infiltration or injury of the seminal cord or tendency to recurrence was the rule in every case, including one very large hernia reaching below the knees. The stump of the sac is fastened 2.5 cm above the inner inguinal ring where the seminal cord emerges, and 4 safety sutures above and below produce a solid muscular wall holding back the stump of the sac. The rows of the sutures do not come above each other, but lap at least 2 cm.

83 Recurrences After Gallstone Operations.—Ehrhardt remarks that the principal causes of recurrence are generally supposed to be the overlooking of concretions, the development of adhesions and the continuance of hysterical disturbances. Infectious plugs of mucus in the biliary passages are liable to simulate true recurrence, but the main cause of recurrence of symptoms is to be sought in the glandular elements of the mucosa which are frequently of abnormal size and development, sometimes extending down to the peritoneal covering of the gall bladder. Inflammation may persist in one of these little recesses in the mucosa—which he calls Luschka's ducts—and possibly a minute concretion in one may be overlooked. They are to the gall bladder what an incipient diverticulum is to the intestine. The practical conclusions are that the best way to prevent recurrence is to remove the gall bladder entirely.

85 Transmission of Syphilis to Dogs.—Hoffmann and Brünig announce that inoculation of two dogs in the cornea with scraps from a human primary syphilitic lesion induced an affection presenting the characteristics of syphilis, even to the positive finding of the pale spirochete. Inoculation in the anterior chamber and also scarification of the cornea, in both rabbits and monkeys, induced a syphilitic keratitis. This confirms the fact that it is not necessary to inoculate the virus into a blood vessel, but that the lymph spaces offer favorable conditions for the proliferation of the spirochetes.

89 Influence of Cholin and Roentgen Rays on Course of Gestation.—The rabbits in the experiments related were injected with cholin or exposed to the Roentgen rays, the results indicating that gestation was arrested and the embryo absorbed under their influence. See editorial in *THE JOURNAL*, May 4, page 1530.

90 Influence of Roentgen Exposures on Nephrectomized Animals.—The toxic effects of the exposures were greater in the nephrectomized animals. This suggests that a leucotoxin is formed under the action of the rays and that this leucotoxin is eliminated by the kidneys.

92 Further Experience with the Benzidin Test for Invisible Hemorrhage.—Examination of the stools from more than 150 patients and urine from 200 patients during the last few months has confirmed the reliability and the accuracy of the benzidin technic. It was described in these columns on page 1334 of the last volume. Admixture of blood from the food may obscure the findings in seeking for minimal hemorrhage in the digestive tract but this error is not possible in examination of the urine. The test with urine is twenty times more sensitive than the Heller urine test and five times more than the guaiac and alon test. The reliability and delicacy of the test render it very valuable for examining for blood in the urine and for hemoglobinuria. The urine must be treated first with glacial acetic acid and ether to prepare it for the test. From 0.5 to 1 cc of glacial acetic acid is added to 10 cc of the urine and lightly shaken. Then about a third of ether, by volume, is added and the whole is thoroughly shaken and set aside for a short time. The separation of the supernatant layer of ether is aided by addition of from 5 to 10 drops of alcohol and slight shaking. The limpid layer of ether is then taken up in a pipette and transferred to another reagent glass containing the benzidin reagent. The contents of the glass are shaken a little to distribute the ether extract through the reagent. In the presence of even traces of blood, the fluid turns green in a few seconds, or blue in case there is much blood present. The benzidin reagent is merely 0.5 cc. of a freshly prepared mixture of benzidin and acetic acid and 2 or 3 cc of a 3 per cent solution of hydrogen dioxide. The specimen of stool, the size of a pea, is suspended in about one fifth of a reagent glass of water and boiled up briefly. A few drops of this suspension are added to the benzidin mixture, in case of the presence of blood the fluid turns green or blue. The patients are not allowed to eat any meat during the three or four days preceding the test. Positive findings then indicate without fail that the source of the blood is in the stomach or intestines. In cases giving negative findings, con

trol examination with other tests never resulted positively. Schlesinger and Holst sum up their experiences, therefore, in the statement that the testimony is all in favor of the accuracy and reliability of the benzidin technic.

93 Operative Treatment of Epilepsy.—Auerbach reviews the opinions and experiences of the most prominent German surgeons on this subject, and reports a case of Jacksonian epilepsy showing remarkable improvement to date after excision of a part of the cortex, 5x15x30 mm., corresponding to the motor disturbances as determined by electric tests. In childhood and youth the results of operative intervention are liable to be better than after 40, as also when the disturbances are more strictly limited to one side, and when there is a history of trauma affecting the head or of an encephalitic process. The disturbances in the case described developed during the incubation stage of scarlet fever, without trauma. He thinks that accumulating evidence is limiting more and more the assumption of an idiopathic epilepsy as some unsuspected underlying lesion is becoming such a frequent discovery.

95 Silver Acetate in Prophylaxis of Ophthalmia Neonatorum.—Seefelder states that he treated one eye with 2 per cent. silver nitrate and the other eye with 1 per cent. silver acetate in 50 infants in his practice and found that the results were fully as good with the acetate as with the nitrate. The acetate has the advantage, he says, that it is harmless under all circumstances, which can not be said of the silver nitrate.

98 String Electrometer.—Cremer has had a string electrometer made, similar to the string galvanometer, and states that it is superior to all other instruments yet devised for electrophysiology. He describes its workings in detail.

99 Urobilinuria in Typhoid.—Rubin gives the tracings of the curve of urobilinuria in eight cases of typhoid fever. They show that very high urobilinuria, in the onset of a febrile affection suggesting typhoid, speaks against its typhoid nature. Pronounced negative findings also have the same significance when the fever is subsiding by lysis. Pronounced urobilinuria accompanying lysis is a good omen, but when the urobilinuria persists into convalescence it should be regarded as an indication for great caution in the diet and in allowing the patient to get up. He should not be dismissed until the urobilin in the urine has returned to normal proportions.

100 Cysticercus in Fourth Ventricle.—Versé describes two cases in which sudden death occurred and autopsy revealed dead cysticerci free in the fourth ventricle. In both cases the foramen of Magendie had been long occluded. The sudden death must have been due to the internal hydrocephalus which had likewise long existed. One of his patients, a woman, died as she sat up in bed.

104 Protection of the Perineum.—Toff remarks that the number of cases of laceration reported from various clinics shows that the technic for preventing injury of the perineum is still far from perfect. He believes that better results could be attained if more regard were paid to the most favorable diameter of the head in guiding delivery. Most of the tears occur while the brow is passing, the suboccipito-frontal diameter being one of the largest, while the occipito-frontal and the mento-occipital are still larger and more dangerous. He stands or sits on the right of the patient, and as soon as the head appears in the vulva he strives to deliver more and more of the back of the head past the symphysis, while forcing the head of the child forward on its breast. After the occiput has passed the symphysis, then the face can be readily delivered, especially if the patient is turned on her left side. Pressing the back of the neck against the symphysis also aids in gaining space to spare the perineum. By this means the shortest diameter of the head, passing from the subocciput to the bregma, is the one involved when the head is emerging. In face presentation the same principle is followed, working out the chin as far in advance as possible, bending the head backward, and delivering the back of the head as the face was delivered above. The technic is illustrated with 6 diagrams.

105 Instrument for Obtaining Blood for Diagnostic Purposes.—Schottelius gives an illustration of a convenient little instrument for obtaining a drop of blood. Two metal rings fit on the

tips of the thumb and forefinger. Each ring is shaped like a broad signet ring, but one has a slit in which works a small triangular knife on a spring. Holding the lobe of the ear between the thumb and forefinger, armed with these rings, pressure on the knife makes the desired little incision, exactly the right size and depth, when the ear can be at once released. The physician can put on the rings and make the incision without attracting the patient's attention to the instrument. It has been in use in his clinic for several years with constant satisfaction.

106 Intratumoral Roentgen Treatment of Cancer.—Streibl has done a large amount of pioneer work in radiotherapy. He advocated three years ago the introduction of radium inside the tumor as a routine procedure in radium treatment of cancer. He has since devised a small Roentgen tube to use in the depths of the tumor. The tumor is incised under adrenalin-Schleich infiltration, the tube is introduced and a weak current turned on. The adrenalin and the pressure of the tube keep the blood expelled from the parts, while most of the radiant energy is utilized, absorption by the skin being abolished. The epidermis is generally assumed to absorb 1/10 of the radiant energy, while the derma proper absorbs more than 1/2. He claims that in ordinary superficial exposures the rays penetrate only a short distance into the tissues, the deeper parts of the tumor escaping most of their influence, and that all this is done away with by this intratumoral exposure which brings the action of the rays exactly where they are most needed. He also says that it obviates danger of the dreaded Roentgen dermatitis, as the rays do not reach the skin first, and that the exposures can be continued as long as desired without fear of cutaneous lesions. One form of the tube has the outer side protected so that the tube can be shoved in under the skin and send its rays downward only, sparing the protected skin above. This has been found useful in treating metastases and tumefied glands near the surface. With these intratumoral exposures "cancer nests" can be thoroughly destroyed without injury to the skin. His experience has convinced him that the formation of antibodies or other immunization processes can be utilized as adjuvants to direct Roentgen treatment of the tumor proper. This he accomplishes by not restricting the exposures to the tumor alone, but by a general application of the rays to larger portions of the body, in order to accelerate the hemolytic processes and thus induce a kind of autoserotherapy in the cancer patient. He adds that recent research showing the marked hemolytic properties of potassium chlorate and the way in which cancer is influenced by it (Lomer) justifies its tentative administration internally and externally as an adjuvant to radiotherapy. He also refers to the works of Werner, Exner, Heineke and others which have demonstrated that local and general Roentgen exposures induce hyperleucocytosis and lymphopeny, that substances appear in the tissues after exposure for which the polynuclear leucocytes display a positive chemotactic affinity, and that exposure of the leucocyte-producing organs checks new formation of leucocytes. He thinks that these facts can be utilized in radiotherapy of cancer, promoting the destruction of the malignant tumor by accelerating the hemolytic processes in general.

- 108 (LXVIII No 2 pp 105-216) *Mouse Tumors and Experimental Transmission of Cancers (Muskekraft og eksperimentel Kreftrforsknig) M. Haaland
109 *Pathogenesis and Treatment of Ulcer of the Stomach (Ulcerus Vetriculi) J. Thesen
110 *Carcinoma of the Prostate with Metastases in Spleen and Peritoneum (Carc. Prostatae) A. Nilsen

108 Mouse Cancers.—Haaland describes his experience with experimental transmission of tumors with research on heredity, immunity etc. He remarks in conclusion that experimental transmission of malignant tumors is still in its infancy and has not yet produced any results that can be applied in practice. It has afforded, however, a number of various factors which influence the tumors and suggested for malignant disease. In of the general constitution of the cancer disease. The cancer is

tumor is due to embryonal or aberrant cells or to an impulse from some unknown parasite, but experimental research has demonstrated that these are not enough—there must be some constitutional predisposition or the cancer cell is unable to proliferate and to produce a tumor. The transplantable mouse tumors enable us to submit this constitutional tendency to experimental tests. The experiments described are susceptible of various explanations, but Haaland thinks that the most plausible is Ehrlich's assumption that the tumor growth is a "fight between cell avidities."

109 Treatment of Ulcer of the Stomach.—Thesen explains gastric ulcer as a chronic, infected ulceration, secondary to some septic process in mouth, nose or throat, accompanied by a local lymphangitis with hyperalgesia of the corresponding parietal peritoneum. The latter is the cause of the pains. He cites statistics to show that the ulcers are always located on parts of the stomach corresponding to certain lymphatic tracts especially the retroperitoneal. The symptoms are explained by this conception of the origin of gastric ulcer, and its correctness is confirmed, he thinks, by his fine results in 35 cases of gastric ulcer in which treatment was based on these premises. He enforces strict bed rest for three weeks, or for six weeks in the older cases, and applies a wet pack around the entire trunk, as he ascribes the pains to the retroperitoneal glands rather than to the stomach itself. He agrees with Lenhartz in regard to the necessity for not starving the already famished patients any more, and he also agrees with those who insist that rest is what the ulcerated stomach needs. He reconciles these apparently contradictory indications by assuming that the food can not directly induce pain in the stomach and that direct irritation of the ulcer has only a very mildly deleterious influence on the ulcer. On the other hand, the slightest movement of the stomach is painful, and any movement of the kind is extremely prejudicial for the healing of the ulcer. He therefore gives his patients all the food they can take without its causing painful movements of the stomach. The quantity is more important in this respect than the quality. The meals must be small and frequent, or, as he expresses it, the ulcer patients do not have any meals but keep lurching all day long—never taking more than from 15 to 100 c.c. at a time. One of his patients could eat a raw plum without hearing from it, but had pain after even a small cup of milk. In case of thirst or too small amounts of urine, he supplies water by rectal injection. The foods that excite the stomach peristalsis least are the white of egg, raw scraped meat and fish, butter and cream, and he restricts the diet to these. He obtains good results from bismuth, but he explains them differently from others, ascribing the benefit to the disinfecting action of the bismuth on the surface of the ulcer and also to the probable fact that the bismuth albuminates formed are taken up by the lymph and are carried into the lymphatics where they exert a direct curative action on the lymphangitis. He does not give the bismuth according to the usual technic, but administers it in suspension in the smallest possible amount of water, in the morning, on the fasting stomach, without previous lavage. He gives the bismuth for five days, then empties the bowels with a copious enema, and recommences the bismuth on the seventh day, until he has thus given fifteen powders. He then suspends the bismuth, as a rule, but has sometimes given up to 45 powders without appreciable harm. All pain generally vanishes by the second powder, and he ascribes to the credit of the bismuth the fact that his patients are so soon able to eat without pain. He has never found blood in the stools after they show traces of bismuth except after severe hematemesis. He has experimented with silver nitrate, but never noted such benefit as after the bismuth, probably because the dosage must be so small. In the first 5 days with 10 gm. of bismuth, the patient is allowed from 350 to 550 c.c. milk, with from 0 to 4 raw eggs. The sixth day no bismuth, but a copious enema. In the next 5 days the food allowed is gradually increased to 750 c.c. milk, 50 c.c. cream, 5 eggs, a little fish and 3 biscuits with butter and raw scraped meat. He gives the bismuth in 100 c.c. of water and allows the patient half this amount of water afterward. The patient then reclines with the pelvis raised for 20 minutes and no food is allowed until after he has rested

quietly for 45 minutes. The milk is given in sips at first, even later, more than 50 c.c. is never allowed at a time. Sometimes substitutes kefir or uses lime water with the milk. After the eighteenth day the patient is allowed to get up. The eggs are given raw at first, but later can be cooked. He does not approve of bread until two or three months after the commencement of the course of treatment.

110 Metastases from Cancer of the Prostate.—In the reported case the carcinoma in the prostate had induced metastases in the seminal vesicles, bladder, peritoneum and spine. In this case the process was an actual osteoplastic carcinoma and the principal symptoms were those of compression of the caudal equina.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sent them. A selection from these volumes will be made for review, dictated by their merits, or in the interest of our readers.

MEDICAL JURISPRUDENCE, FORENSIC MEDICINE AND TOXICOLOGY. By R. A. Witthaus, A.M., M.D., Professor of Chemistry, Physics and Toxicology in Cornell University and Tracy C. Becker, A.B., J.D., Counselor at Law, Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo. With the Collaboration of Others. Second Edition. Volume II. Cloth. Pp. 1008. \$3.00. New York: William Wood & Co., 1907.

PRACTICAL PHYSIOLOGICAL CHEMISTRY, A Book Designed for Use in Courses in Practical Physiological Chemistry in Schools of Medicine and Science. By Philip B. Hawk, M.S., Ph.D., Demonstrator of Physiological Chemistry in the Department of Medicine of the University of Pennsylvania. With Color Plates and Other Illustrations. Cloth. Pp. 416. Price \$4.00. Philadelphia: P. Blakiston's Son & Co., 1907.

DIAGNOSIS OF ORGANIC NERVOUS DISEASES. By Christian A. Herter, M.D., Professor of Pharmacology and Therapeutics at Columbia University. Revised and Enlarged by L. Pierce Clark, M.D., Visiting Neurologist to the Randall's Island Hospitals and Schools. With 109 Illustrations. Cloth. Pp. 690. Price, \$3.00. New York and London: G. P. Putnam's Sons, 1907.

DIE BEHANDLUNG DER ANGEBORENEN HÜFTGELENKVERRENKUNG, UND DER BEHANDLUNG DER TUBERKULÖSEN WIRBELSÄULENERGÜNDUNG VON DR. F. CALOT. Uebersetzt von Dr. P. Ewald. Illustrated, and vorwort von Prof. Dr. Oscar Vulpius. Paper. Stuttgart: Verlag von Ferdinand Enke, 1906-7. (See abstract in THE JOURNAL May 18, page 1728.)

PRACTITIONER'S HANDBOOK OF MATERIA MEDICA AND THERAPEUTICS. Based on Physiological Actions and the Indications in Small Doses, to Which is Added Some Pharmaceutical Data. By Thos. S. Blair, M.D., Member Visiting Staff of Harrisburg City Hospital etc. Cloth. Pp. 253. Price, \$2.00 net. Philadelphia: The Medical Council.

TICS AND THEIR TREATMENT. By Henry Melge and E. Feindel with a Preface by Prof. Brissaud. Translated and Edited with a Critical Appendix by S. A. K. Wilson, M.A., M.B., B.Sc., Resident Medical Officer National Hospital for the Paralyzed and Epileptic, London. Cloth. Pp. 386. Price \$2.50. New York: William Wood & Co., 1907.

SURGICAL DIAGNOSIS. by Daniel N. Eisendrath, A.B., M.D., Adjunct Professor of Surgery in the Medical Department of the University of Illinois College of Physicians and Surgeons. Illustrated partly in colors. Cloth. Pp. 776. Price, \$0.50 net. Philadelphia and London: W. B. Saunders Co., 1907.

SIXTH ANNUAL REPORT OF THE BOARD OF TRUSTEES OF THE NEW YORK STATE HOSPITAL FOR THE TREATMENT OF INCIDENT PULMONARY TUBERCULOSIS. Ray Brook, N. Y. For the Year Ending Dec. 31, 1906. Transmitted to the Legislature Jan. 28, 1907. Paper. Pp. 30. Albany: J. B. Lyon Company.

CLINICAL LECTURES ON NEURASTHENIA, by Thomas D. Savill, M.D., London Physician to the West End Hospital for Diseases of the Nervous System. Third Edition. Revised and Enlarged. Cloth. Pp. 216. Price, \$1.50 net. New York: William Wood & Co., 1907.

GALLSTONES AND DISEASES OF THE BILE-DUCTS. By J. Bland Sutton, F.R.C.S., Eng., Surgeon and Lecturer on Surgery to the Middlesex Hospital. With 48 Illustrations. Cloth. Pp. 234. Price \$2.00. New York: William Wood & Co., 1907.

LESSONS ON MASSAGE by Margaret D. Palmer, Formerly Masseuse and Manager of the Massage Department of the London Hospital. Third Edition. Cloth. Pp. 272. Price, \$2.50 net. New York: William Wood & Co., 1907.

SURGERY OF THE RECTUM. By Fred C. Wallis, B.A., M.D., B.C., Cantab., F.R.C.S., Surgeon to the Charing Cross Hospital. Cloth. Pp. 168. Price, \$2.00 net. New York: William Wood & Co., 1907.

EXPERIMENTS ON ANIMALS. By Stephen Paget. With an Introduction by Lord Lister. Third Edition. Revised. Cloth. Pp. 387. Price, \$3.00. New York: William Wood & Co., 1907.

FORTY-FIFTH GENERAL ASSEMBLY OF ILLINOIS. Index to Senate and House Bills. Paper. Edited and Published by the Bureau of Legislative Publicity, Springfield, Ill.

THE MIRACLE WORKER. By Gerald Maxwell. Frontispiece by G. F. Gray. Cloth. Pp. 340. Price \$1.50. Boston: John W. Luce Co., 1907.

WELLCOME'S PHOTOGRAPHIC EXPOSURE RECORD AND DIARY. 1907. Cloth. Pp. 259. New York and London: Burroughs Wellcome & Co.
